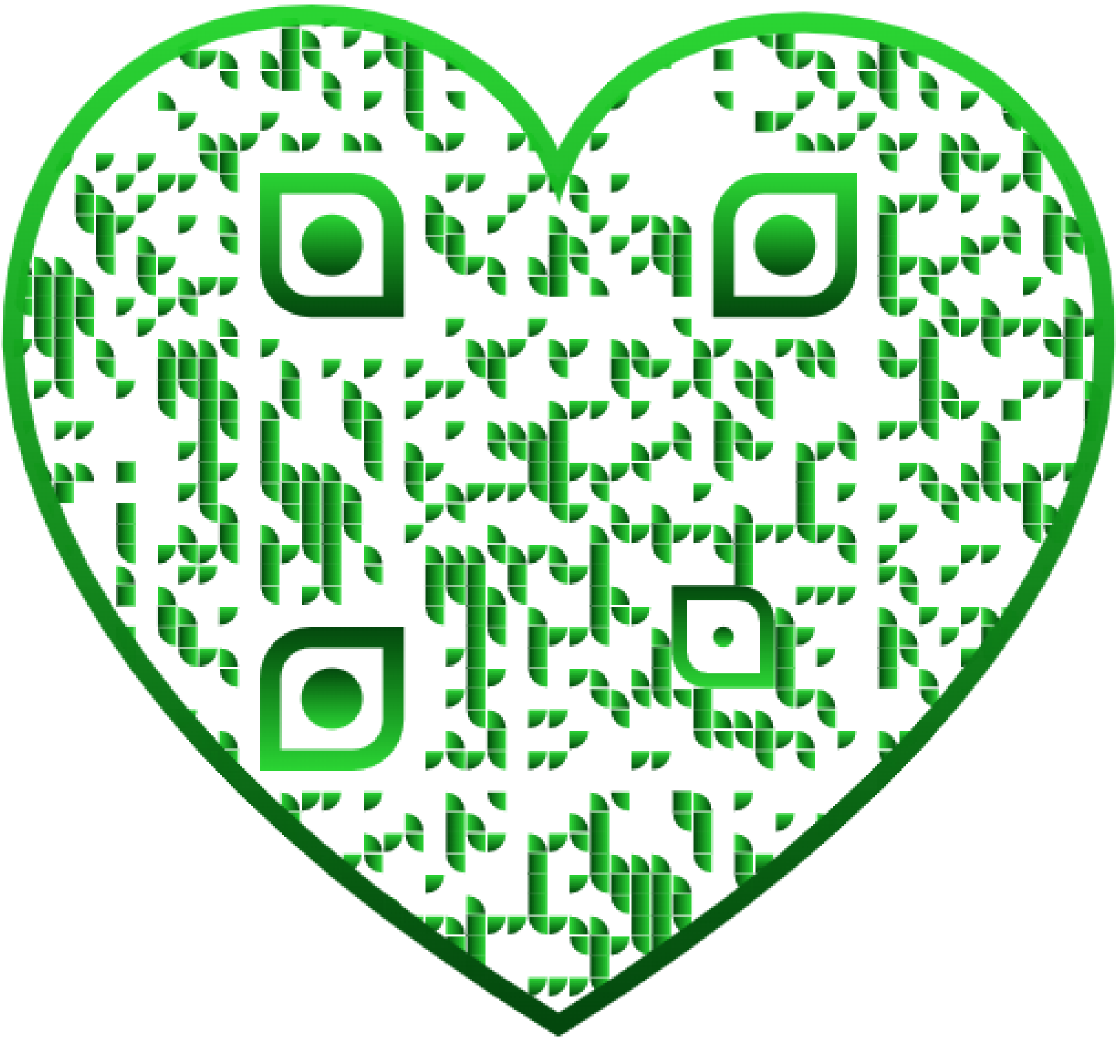
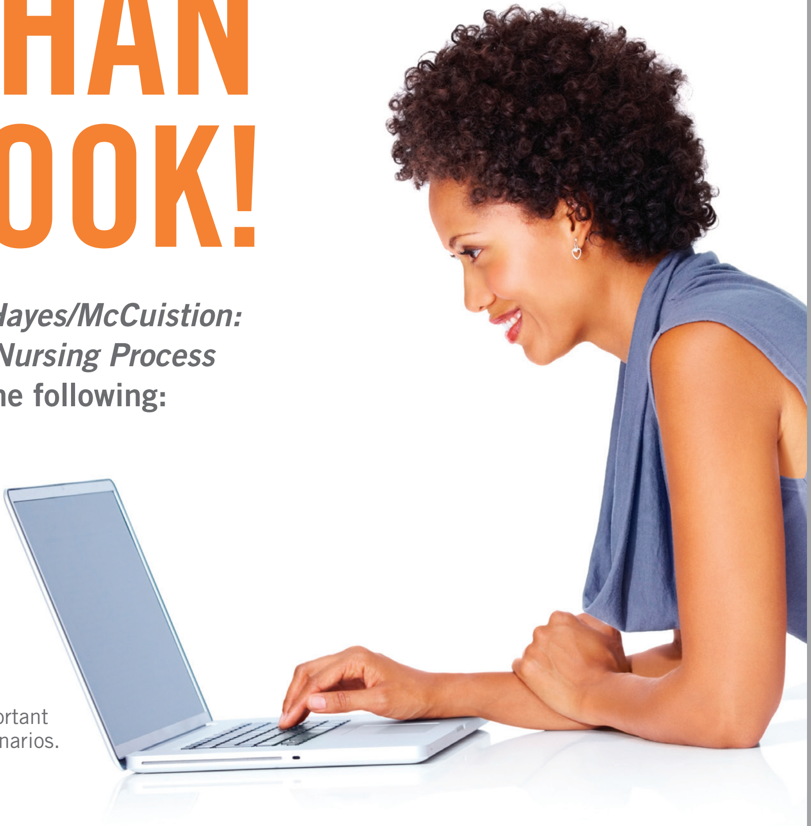
ELSEVIER



ELSEVIER evolve

YOU'VE JUST PURCHASED MORE THAN A TEXTBOOK!



Evolve Student Resources for *Kee/Hayes/McCuistion: Pharmacology: A Patient-Centered Nursing Process Approach, eighth edition,* include the following:

- **Review Questions for the NCLEX® Examination**
  NCLEX® Examination–style review questions for every chapter help you review and apply important content as you prepare for the NCLEX® Examination.
- **Key Points**
  Key Points for every chapter are available as downloadable files so you can review essential chapter content anywhere.
- **Interactive Unfolding Case Studies**
  Case Studies offer an engaging way to apply important pharmacology concepts to true-to-life patient scenarios.
- **Additional Resources**
  Additional resources include animations, videos, and periodic content updates!

CONTENTS

UNIT I INTRODUCTION TO PHARMACOLOGY

1 Drug Action: Pharmaceutic, Pharmacokinetic, and Pharmacodynamic Phases, 2
2 The Drug Approval Process, 14
3 Cultural and Pharmacogenetic Considerations, 21
4 Drug Interactions and Over-the-Counter Drugs, 29
5 Drugs of Abuse, 41
6 Herbal Therapies, 61
7 Pediatric Pharmacology, 79
8 Geriatric Pharmacology, 88
9 Collaboration in Community Settings, 98
10 The Role of the Nurse in Drug Research, 105

UNIT II A NURSE'S PERSPECTIVE OF PHARMACOLOGY

11 The Nursing Process in Patient-Centered Pharmacotherapy, 113
12 Safety and Quality in Pharmacotherapy, 120
13 Medication Administration, 133

UNIT III DRUG CALCULATIONS

14 Medications and Calculations, 148

UNIT IV NUTRITION AND ELECTROLYTES

15 Vitamin and Mineral Replacement, 211
16 Fluid and Electrolyte Replacement, 223
17 Nutritional Support, 243

UNIT V AUTONOMIC NERVOUS SYSTEM AGENTS

18 Adrenergic Agonists and Adrenergic Blockers, 255
19 Cholinergic Agonists and Anticholinergics, 268

UNIT VI NEUROLOGIC AND NEUROMUSCULAR AGENTS

20 Central Nervous System Stimulants, 284
21 Central Nervous System Depressants, 291
22 Anticonvulsants, 304
23 Drugs for Neurologic Disorders: Parkinsonism and Alzheimer's Disease, 314
24 Drugs for Neuromuscular Disorders: Myasthenia Gravis, Multiple Sclerosis, and Muscle Spasms, 326

UNIT VII PAIN AND INFLAMMATION MANAGEMENT AGENTS

25 Antiinflammatory Drugs, 336
26 Nonopioid and Opioid Analgesics, 352

UNIT VIII PSYCHIATRIC AGENTS

27 Antipsychotics and Anxiolytics, 370
28 Antidepressants and Mood Stabilizers, 386

UNIT IX ANTIBACTERIAL AND ANTIINFECTIVE AGENTS

29 Penicillins and Cephalosporins, 400
30 Macrolides, Tetracyclines, Aminoglycosides, and Fluoroquinolones, 414
31 Sulfonamides, 429

UNIT X ADDITIONAL ANTIINFECTIVE AGENTS

32 Antituberculars, Antifungals, Peptides, and Metronidazole, 436
33 Antivirals, Antimalarials, and Anthelmintics, 448
34 Drugs for Urinary Tract Disorders, 460

UNIT XI IMMUNOLOGIC AGENTS

35 HIV- and AIDS-Related Drugs, 469
36 Vaccines, 489

UNIT XII ANTINEOPLASTIC AGENTS

37 Anticancer Drugs, 502
38 Targeted Therapies to Treat Cancer, 530
39 Biologic Response Modifiers, 554

UNIT XIII RESPIRATORY AGENTS

40 Drugs for Upper Respiratory Disorders, 573
41 Drugs for Lower Respiratory Disorders, 583

UNIT XIV CARDIOVASCULAR AGENTS

42 Cardiac Glycosides, Antianginals, and Antidysrhythmics, 601
43 Diuretics, 620
44 Antihypertensives, 633
45 Anticoagulants, Antiplatelets, and Thrombolytics, 650
46 Antihyperlipidemics and Peripheral Vasodilators, 664

UNIT XV GASTROINTESTINAL AGENTS

47 Drugs for Gastrointestinal Tract Disorders, 676
48 Antiulcer Drugs, 693

UNIT XVI EYE, EAR, AND SKIN AGENTS

49 Drugs for Eye and Ear Disorders, 709
50 Drugs for Dermatologic Disorders, 727

UNIT XVII ENDOCRINE AGENTS

51 Endocrine Drugs: Pituitary, Thyroid, Parathyroid, and Adrenal Disorders, 742
52 Antidiabetics, 758

UNIT XVIII REPRODUCTIVE AND GENDER-RELATED AGENTS

53 Female Reproductive Cycle I: Pregnancy and Preterm Labor Drugs, 777
54 Female Reproductive Cycle II: Labor, Delivery, and Preterm Neonatal Drugs, 800
55 Postpartum and Newborn Drugs, 826
56 Drugs for Women's Reproductive Health and Menopause, 845
57 Drugs for Men's Health and Reproductive Disorders, 873
58 Drugs for Disorders in Women's Health, Infertility, and Sexually Transmitted Infections, 885

UNIT XIX EMERGENCY AGENTS

59 Adult and Pediatric Emergency Drugs, 909

APPENDIX A
Therapeutic Drug Monitoring, 927

APPENDIX B
Selected Potential Weapons of Bioterrorism, 932

REFERENCES, 934

INDEX, 939

Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

MEET THE AUTHORS

JOYCE LEFEVER KEE

Joyce LeFever Kee received her Bachelor of Science and Master of Science degrees in Nursing from the University of Maryland and earned 36 postgraduate credits from the University of Delaware. She was a distinguished faculty educator at the University of Maryland for 4 years and at the University of Delaware for 27 years.

Joyce is a member of the Sigma Theta Tau Nursing Honor Society and Phi Kappa Phi Honor Society. She received the Excellence in Teaching Award from and was inducted into the Mentor's Circle at the University of Delaware.

Joyce gave numerous lectures and presentations throughout the United States from 1970 to 1990. She has written various articles, particularly on fluids and electrolytes, laboratory and diagnostic tests, and research projects, in the *American Journal of Nursing, Nursing Clinics of North America, Nursing Journal,* and *Critical Care Quarterly.* She has participated in several research studies on "Identification of Hypertensive Young Adults."

Joyce has authored and coauthored several text and reference books, including *Fluids and Electrolytes with Clinical Applications*, eighth edition; *Handbook of Fluid, Electrolyte, and Acid-Base Imbalances,* third edition; *Clinical Calculations in General and Specialty Areas,* seventh edition; *Laboratory and Diagnostic Tests with Nursing Implications,* ninth edition; and *Handbook of Laboratory and Diagnostic Tests with Nursing Implications,* seventh edition.

Joyce and her husband enjoy traveling all over the world.

EVELYN R. HAYES

Evelyn (Lyn) R. Hayes received her Bachelor of Science in Nursing from Cornell University—New York Hospital School of Nursing; an MPH in Public Health Nursing from the University of North Carolina, School of Public Health, in Chapel Hill, North Carolina; and a PhD in Higher Education from Boston College. In addition, she completed a Post Master's Certificate as Family Nurse Practitioner at the University of Massachusetts at Amherst and is a certified family nurse practitioner. Her professional practice experience includes both acute care institutions and the community setting. Currently she is a Professor in the School of Nursing, College of Health Sciences, at the University of Delaware. In this role, she has vast experience with a variety of teaching modalities at both the undergraduate and graduate levels and experience with distance learning. Reflective of a global focus, Lyn has provided consultation to university faculty in Taiwan and Panama.

A strong advocate of health promotion, Lyn served as Project Director and co-investigator of a U.S. Public Health Service grant promoting healthy lifestyles in Delaware. She was a finalist for the Excellence in Community Based Nursing Practice Award sponsored by the Delaware Nurses Association and Delaware Organization of Nurse Executives.

As author, coauthor, and collaborative team member, she has published in multiple journals. Research interests include smoking cessation in teens and young adults, online caregiver support groups, and the meaning of storytelling of military experience by veterans at end of life. In addition, Lyn has made multiple presentations at regional, national, and international professional meetings.

Throughout her career, Lyn has assumed member and leadership positions at various levels within the University of Delaware as well as professional and community organizations. She ably provides long-term service and leadership to Sigma Theta Tau International, the American Nurses Association, the National League for Nursing Accrediting Commission (NLNAC), and the Delaware Nurses Association.

Now a retired colonel in the United States Army Reserve, Lyn's last assignment was as Principal Reservist to Deputy Commander for Nursing, Walter Reed Army Medical Center, Washington, DC. When at her home base, she enjoys being creative with crafts and spending time with family and friends.

LINDA E. MCCUISTION

Dr. Linda E. McCuistion received a Diploma of Nursing from the Lutheran Hospital School of Nursing in Fort Wayne, Indiana; Bachelor of Science in Nursing from William Carey College in Hattiesburg, Mississippi; Masters in Nursing from Louisiana State University Medical Center; and PhD in Curriculum and Instruction from the University of New Orleans. She was licensed as an Advanced Practice Nurse in Louisiana and has many years of nursing experience, including acute care and home health nursing. For 20 years, Linda was a Nursing Professor at Our Lady of Holy Cross College in New Orleans, Louisiana. She received an Endowed Professorship Award in 2000 and 2003. Linda is currently a Nursing Professor at South University, Richmond, Virginia.

Linda has served as a past president, vice president, and faculty advisor of the Sigma Theta Tau International Honor Society in Nursing, Xi Psi chapter-at-large. She is a past associate editor of the *NODNA Times*, a New Orleans District Nurses' Association newsletter. She has been a member of Phi Delta Kappa and The American Society of Hypertension.

Linda was coordinator for the Graduate Plus Internship Program, a preceptorship program for new nursing graduates in the state of Louisiana. She has served as a legal nurse consultant; a member of a medical review panel; advisory board member, consultant, and reviewer of a software preparation company focused on the state licensure examination; advisory board member for a school for surgical technicians; and consultant to a local hospital to improve the quality of nursing care and assist acute care facilities in preparation for accreditation.

Linda was chosen as a "Great One Hundred Nurse" by the New Orleans District Nurses' Association in 1993. She is also listed in the 2005/2006 edition of the Empire Who's Who Executive and Professional Registry.

Linda has given numerous lectures and presentations regionally and nationally on a variety of nursing topics. She has published articles in nursing journals and authored many chapters in several nursing textbooks, including *Pharmacotherapeutics: Clinical Decision-Making in Nursing* (1999), *Saunders Manual of Medical-Surgical Nursing: A Guide for Clinical Decision-Making* (2002), and the *Saunders Nursing Survival Guide: Pathophysiology* (2007). She is author and coauthor of many chapters and co-editor of the *Saunders Nursing Survival Guide: Pharmacology* (2007).

Linda enjoys cruises and other travel. When at home, she enjoys family, friends, crafts, golf, and writing.

PREFACE

The eighth edition of *Pharmacology: A Patient-Centered Nursing Process Approach* is written for students in a variety of nursing programs who can benefit from its presentation of the principles of pharmacology in a straightforward, student-friendly manner. It focuses on need-to-know content and helps students learn to administer drugs safely and eliminate medication errors through extensive practice of dosage calculations and careful application of the nursing process.

ORGANIZATION

Pharmacology: A Patient-Centered Nursing Process Approach is organized into 19 units and 59 chapters. **Unit I** is an introduction to pharmacology and includes thoroughly updated chapters on drug action, the drug approval process, cultural and pharmacogenetic considerations, drug interactions, over-the-counter drugs, drugs of abuse, herbal therapies, lifespan issues, patient collaboration in community settings, and the role of the nurse in drug research.

Unit II focuses on patient care and safety, with completely revised and updated chapters on the nursing process in patient-centered pharmacotherapy, safety and quality in pharmacotherapy, and medication administration. Unit II features an introduction to the QSEN (Quality and Safety Education for Nurses) initiative, with special emphasis on patient-centered care and on the QSEN competencies of safety and quality.

Unit III, a comprehensive review of drug dosage calculations for adults and children, is a unique strength of this book. This unit, tabbed for quick reference, consists of six sections: Systems of Measurement with Conversion, Methods for Calculation, Calculations of Oral Dosages, Calculations of Injectable Dosages, Calculations of Intravenous Fluids, and Pediatric Drug Calculations. Six methods of dosage calculation are presented, with color coding for easy identification: basic formula, ratio and proportion, fractional equation, dimensional analysis, body weight, and body surface area. Integral to Unit III are its clinical practice problems (featuring actual drug labels in full color), which provide extensive practice in real-world dosage calculations. With this wide array of practice problems in a variety of health care settings, the unit eliminates the need to purchase a separate dosage calculations book.

Unit IV addresses nutrition and fluids and electrolytes, with separate chapters covering vitamin and mineral replacement, fluid and electrolyte replacement, and nutritional support.

Units V through XIX make up the core of *Pharmacology: A Patient-Centered Nursing Process Approach* and cover the drug families that students must understand to practice effectively. Each drug family chapter includes a chapter outline, learning objectives, key terms, at least one Prototype Drug Chart, a drug table, and an extensive Nursing Process section.

- The **Prototype Drug Charts** are a unique tool that students can use to view the many facets of a prototype drug through the lens of the nursing process. Each prototype drug is one of the common drugs in its drug class. The charts include Drug Class, Trade Names, Contraindications, Dosage, Drug-Lab-Food Interactions, Pharmacokinetics, Pharmacodynamics, Therapeutic Effects/Uses, Side Effects, and Adverse Reactions. With these charts, students can see how the steps of the Nursing Process correlate with these key aspects of drug information and therapy.
- The **drug tables** provide a quick reference to routes, dosages, uses, and key considerations for the most commonly prescribed medications for a given class. They list drug names (generic, brand, and Canadian), dosages, uses and considerations, pregnancy categories, and specific information on half-life and protein-binding.
- The **Nursing Process sections** provide a convenient summary of how to assess a patient, develop nursing diagnoses, determine and follow through with the plan of care, and evaluate the outcomes of your efforts. These sections also include cultural content, nursing interventions, suggestions for patient teaching, and relevant herbal information.

ADDITIONAL FEATURES

Throughout this edition, we have retained, enhanced, and added a variety of features that teach students the fundamental principles of pharmacology and the role of the nurse in drug therapy:

- **NCLEX Study Questions** at the end of each chapter help prepare students for the NCLEX examination with its increasing emphasis on pharmacology; answers are listed upside down below the questions for quick feedback.
- **Safety: Preventing Medication Errors boxes** have been updated and include information on packaging, dosages, look-alike and sound-alike drugs, and other causes of medication errors.
- **Key Terms** include page numbers and are defined in the text to enhance this "built-in glossary" feature for students.
- **Canadian drug names** are identified with **a special maple-leaf icon** (🍁).
- **Critical Thinking Case Studies** conclude many chapters. These clinical scenarios are followed by a series of questions, challenging students to carefully consider the scenario and apply their knowledge and analytical skills to respond to the situations.

- **Herbal Alerts** appear throughout the text, providing students with a quick reference to information on popular herbs and their side effects, drug interactions, and more.
- **Anatomy and physiology.** Unit openers for all drug therapy chapters include illustrated overviews of normal anatomy and physiology. These introductions give students the foundation for understanding how drugs work in various body systems.
- **High-alert drugs** (denoted with the symbol 🚩), **evidence-based practice** (denoted with the symbol 🔍), and **safety concerns** (denoted with the symbol ⚡) are identified within the text with distinctive icons that make it easy to find crucial information.

TEACHING AND LEARNING RESOURCES

The eighth edition of *Pharmacology: A Patient-Centered Nursing Process Approach* is the core of a complete teaching and learning package for nursing pharmacology. Additional components of this package include resources for students, resources for faculty members, and resources for both students and faculty.

For Students

A comprehensive *Study Guide,* available for purchase separately, provides thousands of study questions and answers, including clinically based situational practice problems, drug calculation problems and questions (many with actual drug labels), and case studies to help students master textbook content. Answers are provided at the end of the *Study Guide.*

A completely updated Evolve website (http://evolve.elsevier.com/KeeHayes/pharmacology/) provides additional resources for students, including the following:

- **Review Questions for the NCLEX® Examination** organized by chapter
- **Downloadable Key Points** for content review on-the-go
- **Pharmacology animations** and **videos**
- **Unfolding Case Studies** with review questions
- **References** from the textbook

For Faculty Members

The updated faculty Evolve website (http://evolve.elsevier.com/KeeHayes/pharmacology/) includes all of the student resources mentioned previously, plus the following instructor-only resources:

- ***TEACH for Nurses* Lesson Plans (NEW for this edition!)** focus on the most important content from each chapter and provide innovative strategies for student engagement and learning. The Lesson Plans include strategies for integrating nursing curriculum standards (QSEN, concept-based learning, and BSN essentials), links to all relevant student and instructor resources, and an original instructor-only case study in each chapter.
- **ExamView Test Bank** features more than 1000 NCLEX® Examination–format questions, including alternate-item questions, as well as rationales and page references for each question.
- **PowerPoint Collection** features customizable slides with images, integrated Audience Response System Questions, and new unfolding case studies with questions.
- **Image Collection** provides approximately 125 full-color images from the book.

This textbook may be supplemented with the drug content found on government agency websites, which supply the latest information regarding changes to drug brand names. It is our hope that *Pharmacology: A Patient-Centered Nursing Process Approach* and its comprehensive ancillary package will serve as a dynamic resource for teaching students the basic principles of pharmacology and their vital role in drug therapy.

Joyce LeFever Kee
Evelyn R. Hayes
Linda E. McCuistion

ACKNOWLEDGMENTS

We wish to extend our sincere appreciation to the many professionals who assisted in the preparation of the eighth edition of *Pharmacology: A Patient-Centered Nursing Process Approach* by reviewing chapters and offering suggestions.

We wish to especially thank the original authors and those who updated the established chapters: Margaret Barton-Burke, Joseph Boullata, Jacqueline Rosenjack Burchum, Katherine L. Byar, Michelle M. Byrne, Karen Carmody, Robin Webb Corbett, Sandy Elliott, Linda Goodwin, Janice Heinssen, Marilyn Herbert-Ashton, Judith W. Herrman, Kathleen J. Jones, Bettyrae Jordan, Robert J. Kizior, Paula R. Klemm, Anne E. Lara, Linda Laskowski-Jones, Ronald J. Lefever, Patricia S. Lincoln, Patricia O'Brien, Laura K. Williford Owens, Byron Peters, Lisa Ann Plowfield, Larry D. Purnell, Nancy C. Sharts-Hopko, Jane Purnell Taylor, Donald L. Taylor, Lynette M. Wachholz, Marcia Welsh, Gail Wilkes, and M. Linda Workman.

Of course, we are deeply indebted to the many patients and students we have had throughout our many years of professional nursing practice. From them we have learned many fine points about the role of therapeutic pharmacology in nursing practice.

Our deepest appreciation goes to pharmaceutical companies for use of their drug labels. Pharmaceutical companies that extended their courtesy to this book include the following:

Abbott Laboratories
AstraZeneca Pharmaceuticals
Aventis
Bayer Corporation
Bristol-Myers Squibb (including Apothecon Laboratories and Mead Johnson Pharmaceuticals)
DuPont/Merck Pharmaceuticals
Eli Lilly and Company
Elkins-Sinn, Inc.
Glaxo-Wellcome
Marion Merrell Dow, Inc.
McNeill Laboratory, Inc.
Merck and Co., Inc.
Parke-Davis Co.
Pfizer Inc.
Rhone-Poulenc Rorer
SmithKline Beecham Pharmaceutical
Wyeth-Ayerst Laboratories

Thanks to Becton, Dickinson and Company for the syringe displays. Thanks to CareFusion Corporation for the photos of the infusion pumps.

Our sincere thanks to Elsevier, especially Lee Henderson, Executive Content Strategist; Jennifer Ehlers, Content Manager; Clay Broeker, Senior Project Manager; and Jeff Patterson, Publishing Services Manager, for their suggestions and assistance.

Joyce LeFever Kee
Evelyn R. Hayes
Linda E. McCuistion

UNIT I

Introduction to Pharmacology

Assessing a patient's response to drug therapy is an ongoing nursing responsibility. To adequately assess, plan, intervene, and evaluate drug effects, the nurse must have knowledge of the pharmaceutic, pharmacokinetic, and pharmacodynamic phases of drug action, all of which are described in Chapter 1, Drug Action: Pharmaceutic, Pharmacokinetic, and Pharmacodynamic Phases.

The rest of the unit is composed of nine chapters that cover a range of important issues affecting drug therapy and nursing. Chapter 2, The Drug Approval Process, discusses drug standards and federal legislation for American and Canadian drugs that establish safety guidelines for drug use, drug names, and drug resources.

Chapter 3, Cultural and Pharmacogenetic Considerations, helps the nurse understand and respond to unique cultural and genetic factors that may influence drug therapy for a particular patient. Factors such as heritage, communication styles, family organization, spirituality and religion, health beliefs and practices, biocultural ecology, and traditional medicine are discussed.

Chapter 4, Drug Interactions and Over-the-Counter Drugs, and Chapter 5, Drugs of Abuse, cover two areas of special interest to nurses. Assessing drug interaction has always been and remains an ongoing function of the nurse. Because drug abuse is a national problem from which no portion of the population is immune—including health professionals—it is a topic of great concern to nurses.

Chapter 6, Herbal Therapies, explores herbal-based preparations that are available over the counter. It covers the most commonly used herbs and discusses their indications, preparation, dosages, potential hazards, and tips for safe and effective use.

Chapter 7, Pediatric Pharmacology, and Chapter 8, Geriatric Pharmacology, cover pharmacokinetic and pharmacodynamic effects specific to these age groups. They also discuss the special attention required when administering drugs to these age groups.

With the increasing movement of health care into the community, nurses are gaining more responsibilities and opportunities to collaborate with patients in safe medication administration and use. Chapter 9, Collaboration in Community Settings, focuses on aspects of drug therapy unique to the home, school, workplace, and other alternative care settings.

Chapter 10, The Role of the Nurse in Drug Research, discusses the nurse's challenges regarding drug research. In general practice, the nurse identifies specific needs that may be met by medications. When part of clinical drug trials, the nurse must be aware of informed consent issues and patient responses to drugs.

OBJECTIVES

- Differentiate the three phases of drug action.
- Discuss the two processes that occur before tablets are absorbed into the body.
- Describe the four processes of pharmacokinetics.
- Explain the meaning of pharmacodynamics, dose response, maximal efficacy, receptors, and nonreceptors in drug action.
- Define the terms *protein-bound drugs, half-life, therapeutic index, therapeutic drug range, side effects, adverse reaction,* and *drug toxicity.*
- Check drugs for half-life, percentage of protein-binding effect, therapeutic range, and side effects in a drug reference book.
- Describe the nursing implications of pharmacokinetics and pharmacodynamics.

A tablet or capsule taken by mouth goes through three phases—pharmaceutic, pharmacokinetic, and pharmacodynamic—as drug actions occur. In the **pharmaceutic phase,** the drug becomes a solution so that it can cross the biologic membrane. When the drug is administered parenterally by subcutaneous (subQ), intramuscular (IM), or intravenous (IV) routes, there is no pharmaceutic phase. The second phase, the pharmacokinetic phase, is composed of four processes: absorption, distribution, metabolism (or biotransformation), and excretion (or elimination). In the pharmacodynamic phase, a biologic or physiologic response results.

PHARMACEUTIC PHASE

Approximately 80% of drugs are taken by mouth. The pharmaceutic phase (dissolution) is the first phase of drug action. In the gastrointestinal (GI) tract, drugs need to be in solution so they can be absorbed. A drug in solid form (tablet or capsule) must disintegrate into small particles to dissolve into a liquid, a process known as *dissolution*. Drugs in liquid form are already in solution. Figure 1-1 displays the pharmaceutic phase of a tablet.

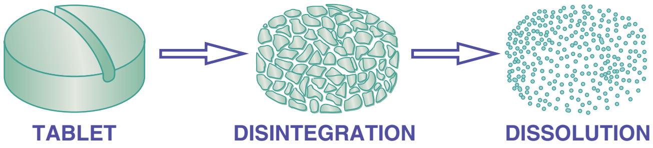

FIGURE 1–1 The two pharmaceutic phases are disintegration and dissolution.

Tablets are not 100% drug. Fillers and inert substances, generally called **excipients,** are used in drug preparation to allow the drug to take on a particular size and shape and to enhance drug dissolution. Some additives in drugs, such as the ions potassium (K) and sodium (Na) in penicillin potassium and penicillin sodium, increase the absorbability of the drug. Penicillin is poorly absorbed by the GI tract because of gastric acid. However, by making the drug a potassium or sodium salt, penicillin can then be absorbed. **Disintegration** is the breakdown of a tablet into smaller particles. **Dissolution** is the dissolving of the smaller particles in the GI fluid before absorption. Rate of dissolution is the time it takes the drug to disintegrate and dissolve to become available for the body to absorb it. Drugs in liquid form are more rapidly available for GI absorption than are solids. Generally, drugs are both disintegrated and absorbed faster in acidic fluids with a pH of 1 or 2 rather than in alkaline fluids. Alkaline drugs would become ionized and have difficulty crossing cell membrane barriers. Both the very young and older adults have less gastric acidity; therefore, drug absorption is generally slower for those drugs absorbed primarily in the stomach.

Enteric-coated drugs resist disintegration in the gastric acid of the stomach, so disintegration does not occur until the drug reaches the alkaline environment of the small intestine. Enteric-coated tablets can remain in the stomach for a long time; therefore, their effect may be delayed in onset. Enteric-coated tablets or capsules and sustained-release (beaded) capsules should not be crushed. Crushing would alter the place and time of absorption of the drug. Food in the GI tract may interfere with the dissolution of certain drugs. Some drugs irritate the gastric mucosa, so fluids or food may be necessary to dilute the drug concentration and to act as protectants.

PHARMACOKINETIC PHASE

Pharmacokinetics is the process of drug movement to achieve drug action. The four processes are absorption, distribution, metabolism (or biotransformation), and excretion (or elimination). The nurse applies knowledge of pharmacokinetics when assessing the patient for possible adverse drug effects. The nurse communicates assessment findings to members of the health care team in a timely manner to promote safe and effective drug therapy for the patient.

Absorption

Absorption is the movement of drug particles from the GI tract to body fluids by passive absorption, active absorption, or pinocytosis. Most oral drugs are absorbed into the surface area of the small intestine through the action of the extensive mucosal villi. Absorption is reduced if the villi are decreased in number because of disease, drug effect, or the removal of small intestine. Protein-based drugs such as insulin and growth hormones are destroyed in the small intestine by digestive enzymes. **Passive absorption** occurs mostly by diffusion (movement from higher concentration to lower concentration). With the process of diffusion, the drug does not

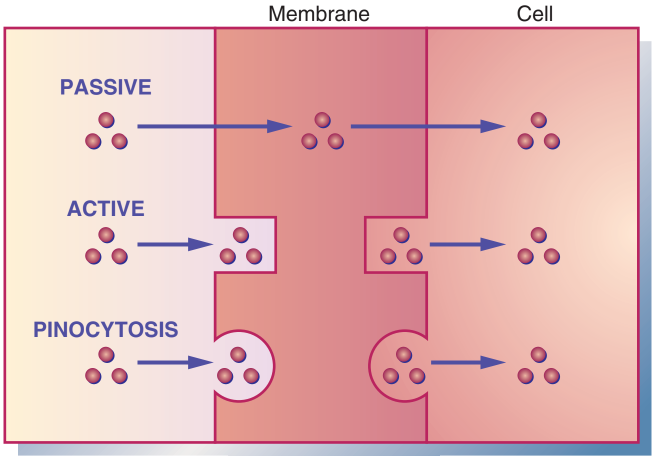

FIGURE 1–2 The three major processes for drug absorption through the gastrointestinal membrane are passive absorption, active absorption, and pinocytosis.

require energy to move across the membrane. **Active absorption** requires a carrier such as an enzyme or protein to move the drug against a concentration gradient. Energy is required for active absorption. **Pinocytosis** is a process by which cells carry a drug across their membrane by engulfing the drug particles (Figure 1-2).

The GI membrane is composed mostly of lipid (fat) and protein, so drugs that are lipid soluble pass rapidly through the GI membrane. Water-soluble drugs need a carrier, either enzyme or protein, to pass through the membrane. Large particles pass through the cell membrane if they are nonionized (have no positive or negative charge). Weak acid drugs such as aspirin are less ionized in the stomach, and they pass through the stomach lining easily and rapidly. An infant's gastric secretions have a higher pH (alkaline) than those of adults; therefore, infants can absorb more penicillin. Certain drugs such as calcium carbonate and many of the antifungals need an acidic environment to achieve greater drug absorption; thus food can stimulate the production of gastric acid. Hydrochloric acid destroys some drugs such as penicillin G; therefore a large oral dosage of penicillin is needed to offset the partial dose loss. Drugs administered by many routes do not pass through the GI tract or liver. These include parenteral drugs, eyedrops, eardrops, nasal sprays, respiratory inhalants, transdermal drugs, and sublingual drugs**. Remember**, drugs that are lipid soluble and nonionized are absorbed faster than water-soluble and ionized drugs.

Blood flow, pain, stress, hunger, fasting, food, and pH affect drug absorption. Poor circulation to the stomach as a result of shock, vasoconstrictor drugs, or disease hampers absorption. Pain, stress, and foods that are solid, hot, or high in fat can slow gastric emptying time, so the drug remains in the stomach longer. Exercise can decrease blood flow by causing more blood to flow to the peripheral muscle, thereby decreasing blood circulation to the GI tract.

Drugs given IM are absorbed faster in muscles that have more blood vessels (e.g., deltoids) than in those that have fewer blood vessels (e.g., gluteals). Subcutaneous tissue has fewer blood vessels, so absorption is slower in such tissue.

Some drugs do not go directly into the systemic circulation following oral absorption but pass from the intestinal lumen to the liver via the portal vein. In the liver, some drugs may be metabolized to an inactive form that may then be excreted, thus reducing the amount of active drug. Some drugs do not undergo metabolism at all in the liver, and others may be metabolized to drug metabolite, which may be equally or more active than the original drug. The process in which the drug passes to the liver first is called the **first-pass effect,** or hepatic first pass.

Most drugs given orally are affected by first-pass metabolism. Lidocaine and some nitroglycerins are not given orally because they have extensive first-pass metabolism and therefore most of the dose would be destroyed.

Bioavailability is a subcategory of absorption. It is the percentage of the administered drug dose that reaches the systemic circulation. For the oral route of drug administration, bioavailability occurs after absorption and first-pass metabolism. The percentage of bioavailability for the oral route is always less than 100%, but for the IV route it is 100%. Oral drugs that have a high first-pass hepatic metabolism may have a bioavailability of only 20% to 40% on entering systemic circulation. To obtain the desired drug effect, the oral dose could be higher than the drug dose for IV use.

Factors that alter bioavailability include (1) the drug form (e.g., tablet, capsule, sustained-release, liquid, transdermal patch, rectal suppository, inhalation), (2) route of administration (e.g., oral, rectal, topical, parenteral), (3) GI mucosa and motility, (4) food and other drugs, and (5) changes in liver metabolism caused by liver dysfunction or inadequate hepatic blood flow. A decrease in liver function or a decrease in hepatic blood flow can increase the bioavailability of a drug, but only if the drug is metabolized by the liver. Less drug is destroyed by hepatic metabolism in the presence of liver disorder.

With some oral drugs, rapid absorption increases the bioavailability of the drug and can cause an increase in drug concentration. Drug toxicity may result. Slow absorption can limit the bioavailability of the drug, thus causing a decrease in drug serum concentration.

Distribution

Distribution is the process by which the drug becomes available to body fluids and body tissues. Drug distribution is influenced by blood flow, the drug's affinity to the tissue, and the **protein-binding effect** (Figure 1-3). In addition, volume of drug distribution (Vd) is dependent on drug dose and its concentration in the body. Drugs with a larger volume of drug distribution have a longer half-life and stay in the body longer. See the section on metabolism, or biotransformation, later in this chapter.

Protein Binding

As drugs are distributed in the plasma, many are bound to varying degrees (percentages) with protein (primarily albumin). Drugs that are greater than 89% bound to protein are known as *highly protein-bound drugs*; drugs that are 61%

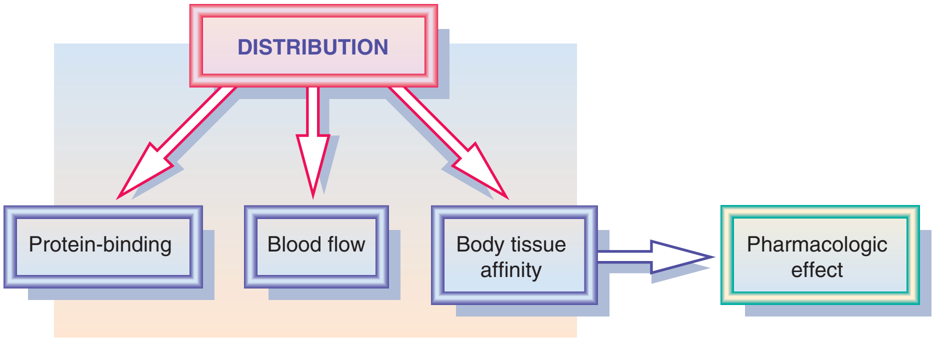

FIGURE 1–3 Drug distribution.

to 89% bound to protein are moderately highly protein-bound; drugs that are 30% to 60% bound to protein are moderately protein-bound; and drugs that are less than 30% bound to protein are low protein-bound drugs. Table 1-1 lists selected highly protein-bound drugs and moderately highly protein-bound drugs. The portion of the drug that is bound is inactive because it is not available to receptors, and the portion that remains unbound is free, active drug. Only **free drugs** (drugs not bound to protein) are active and can cause a pharmacologic response. As the free drug in the circulation decreases, more bound drug is released from the protein to maintain the balance of free drug. Drugs bound to proteins cannot leave the systemic circulation to get to the site of action. This is why only free drug is active.

When two highly protein-bound drugs are given concurrently, they compete for protein-binding sites, thus causing more free drug to be released into the circulation. In this situation, drug accumulation and possible drug toxicity can result. Also, a low serum protein level decreases the number of protein-binding sites and can cause an increase in the amount of free drug in the plasma. Drug toxicity may then result. Drug dose is prescribed according to the percentage in which the drug binds to protein.

Patients with liver or kidney disease or those who are malnourished may have an abnormally low serum albumin level. This results in fewer protein-binding sites, which in turn leads to excess free drug and eventually to drug toxicity. Older adults are more likely to have hypoalbuminemia. With some health conditions that result in a low serum protein level, excess free or unbound drug goes to nonspecific tissue binding sites until needed and excess free drug in the circulation does not occur. Consequently, a decreased drug dose is needed as there is not as much protein circulated for the drug to bind to.

Some drugs bind with a specific protein component such as albumin or globulin. Most anticonvulsants bind primarily to albumin. Some basic drugs such as antidysrhythmics (e.g., lidocaine, quinidine) bind mostly to globulins.

To avoid possible drug toxicity, checking the protein-binding percentage of all drugs administered to a patient is important. The nurse should also check the patient's plasma protein and albumin levels, because a decrease in plasma protein (albumin) decreases protein-binding sites, permitting

TABLE 1-1 PROTEIN-BINDING AND HALF-LIFE OF DRUGS

DRUG	PROTEIN-BOUND (%)	HALF-LIFE (t½) (h)
Highly Protein-Bound Drugs (89%)		
amitriptyline	97	40
chlorpromazine	95	30
diazepam	98	30-80

valproic acid	92	15
warfarin	97	20-60
Moderately High Protein-Bound Drugs (61% to 89%)		
erythromycin	70	3
nafcillin	86	2-20
phenytoin	88	10-40
quinidine	70	6
trimethoprim	70	11
Moderately Protein-Bound Drugs (30% to 60%)		
aspirin	49	0.25-2
lidocaine	50	2
meperidine	56	3
pindolol	40	3-4
theophylline	60	9
ticarcillin	45-65	1-1.5
Low Protein-Bound Drugs (30%)		
amikacin	4-11	2-3
amoxicillin	20	1-1.5
atenolol	6-16	6-7
cephalexin	10-15	0.5-1.2
digoxin	25	36
neostigmine bromide	15-25	1-1.5
terbutaline sulfate	25	3-11
timolol maleate	<10	3-4
tobramycin sulfate	10	2-3

h, Hour; >, greater than; <, less than.

more free drug in the circulation. Depending on the drug, the result could be life-threatening.

Abscesses, exudates, body glands, and tumors hinder drug distribution. Antibiotics do not distribute well at abscess and exudate sites. In addition, some drugs accumulate in particular tissues such as fat, bone, liver, muscle, and eye tissues.

The blood-brain barrier (BBB) is a semipermeable membrane in the central nervous system (CNS) that protects the brain from foreign substances. Highly lipid-soluble drugs are able to cross the BBB. Drugs that are not bound to proteins and are not lipid soluble are not able to cross the BBB, which makes it difficult to distribute the drug (Figure 1-4).

During pregnancy, both lipid-soluble and lipid-insoluble drugs are able to cross the placental barrier, which can affect the fetus and the mother. The risk-benefit ratio should be considered before drugs are given during pregnancy (Figure 1-5; see also Chapter 53). During lactation, drugs can be secreted into breast milk, which could affect the nursing infant. The nurse needs to check which drugs may cross into breast milk before administering to a lactating patient.

Metabolism, or Biotransformation

Metabolism is the process by which the body inactivates or biotransforms drugs. Drugs can be metabolized in several organs; however, the liver is the primary site of metabolism. Most drugs are inactivated by liver enzymes and are then converted or transformed by hepatic enzymes to inactive metabolites or water-soluble substances for excretion. A large percentage of drugs are lipid soluble; thus the liver metabolizes the lipid-soluble drug substance to a water-soluble substance for renal excretion. However, some drugs are transformed into active metabolites, causing an increased pharmacologic response. Liver diseases such as cirrhosis and hepatitis alter drug metabolism by inhibiting the drug-metabolizing enzymes in the liver. When the drug metabolism rate is decreased, excess drug accumulation can occur and lead to toxicity.

The **half-life** (t½) of a drug is the time it takes for one half of the drug concentration to be eliminated. Metabolism and elimination affect the half-life of a drug. For example, with liver or kidney dysfunction, the half-life of the drug is prolonged and less drug is metabolized and eliminated. When a drug is taken continually, drug accumulation may occur. Table 1-1 shows the half-life of selected drugs.

A drug goes through several half-lives before more than 90% of the drug is eliminated. If the patient takes 650 mg of aspirin and the half-life is 3 hours, it takes 3 hours for the first half-life to eliminate 325 mg, 6 hours for the second half-life to eliminate an additional 162 mg, and so on until the sixth half-life (or 18 hours), when 10 mg of aspirin is left in the body (Table 1-2). A short half-life is considered to be 4 to 8 hours, and a long one is 24 hours or longer. If the drug has a long half-life (such as digoxin at 36 hours), it takes several days for the body to completely eliminate the drug.

By knowing the half-life, the time it takes for a drug to reach a steady state of serum concentration can be computed. Administration of the drug for three to five half-lives

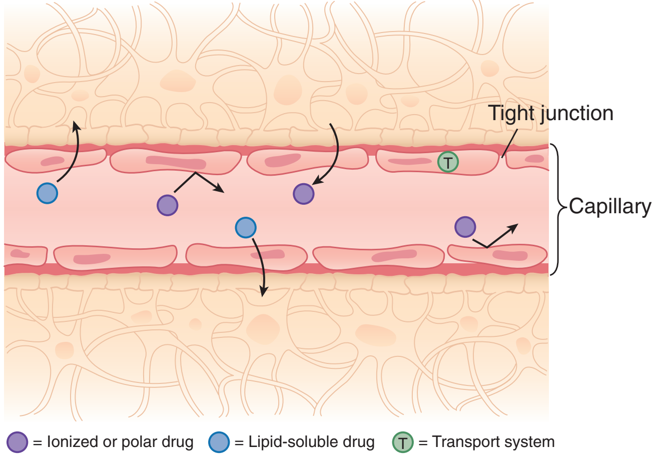

FIGURE 1–4 Drug movement across the blood-brain barrier.

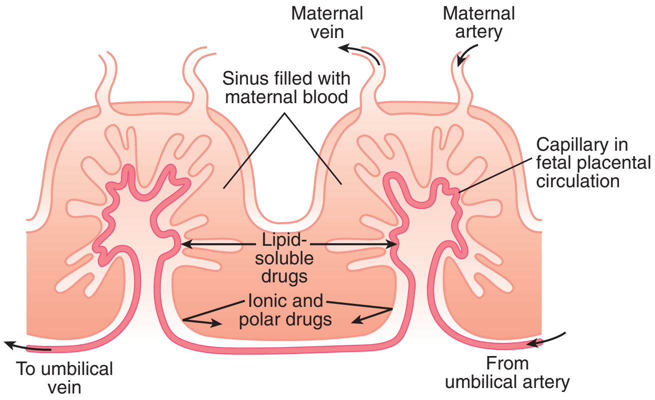

FIGURE 1–5 Drug crossing the placenta.

TABLE 1-2 **HALF-LIFE OF 650 mg OF ASPIRIN**

NUMBER (t½)	TIME OF ELIMINATION (h)	DOSAGE REMAINING (mg)	PERCENTAGE LEFT
1	3	325	50
2	6	162	25
3	9	81	12.5
4	12	40	6.25
5	15	20	3.1
6	18	10	1.55

h, Hour; *t½*, half-life.

saturates the biologic system to the extent that the intake of drug equals the amount metabolized and excreted. An example is digoxin, which has a half-life of 36 hours with normal renal function. It would take approximately 5 days to 1 week (three to five half-lives) to reach a steady state for digoxin concentration.

Excretion, or Elimination

The main route of drug **elimination** is through the kidneys (urine). Other routes include bile, feces, lungs, saliva, sweat, and breast milk. The kidneys filter free unbound drugs, water-soluble drugs, and drugs that are unchanged. The lungs eliminate volatile drug substances and products metabolized to carbon dioxide (CO_2) and water (H_2O).

The urine pH influences drug excretion. Urine pH varies from 4.5 to 8. Acidic urine promotes elimination of weak base drugs, and alkaline urine promotes elimination of weak acid drugs. Aspirin, a weak acid, is excreted rapidly in alkaline urine. If a person takes an overdose of aspirin, sodium bicarbonate may be given to change the urine pH to alkaline to promote excretion of the drug. Large quantities of cranberry juice can decrease urine pH, causing acidic urine and thus inhibiting the elimination of aspirin.

With a kidney disease that results in decreased glomerular filtration rate (GFR) or decreased renal tubular secretion, drug excretion is slowed or impaired. Drug accumulation with possible severe adverse drug reactions can result. A decrease in blood flow to the kidneys can also alter drug excretion.

Common tests used to determine renal function are **creatinine clearance (CLcr)** and blood urea nitrogen (BUN). Creatinine is a metabolic by-product of muscle that is excreted by the kidneys. The creatinine clearance test compares the level of creatinine in the urine with the level of creatinine in the blood. Creatinine clearance varies with age and gender. Lower values are expected in older adult and female patients because of their decreased muscle mass. GFR may be the best test, but it is expensive and not so commonly used. A decrease in GFR results in an increase in serum creatinine level and a decrease in urine creatinine clearance.

With renal dysfunction either in older adults or as a result of kidney disorders, drug dosage usually needs to be decreased. In these cases, the creatinine clearance needs to be determined to establish appropriate drug dosage. When the creatinine clearance is decreased, drug dosage likewise may need to be decreased. Continuous drug dosing according to a prescribed dosing regimen without evaluating creatinine clearance could result in drug toxicity.

PHARMACODYNAMIC PHASE

Pharmacodynamics is the study of the way drugs affect the body. Drug response can cause a primary or secondary physiologic effect or both. The primary effect is desirable, and the secondary effect may be desirable or undesirable. An example of a drug with a primary and secondary effect is diphenhydramine (Benadryl), an antihistamine. The primary effect of diphenhydramine is to treat the symptoms of allergy, and the secondary effect is a central nervous system depression that causes drowsiness. The secondary effect is undesirable when the patient drives a car, but at bedtime it could be desirable because it causes mild sedation.

Dose Response and Maximal Efficacy

Dose response is the relationship between the minimal versus the maximal amount of drug dose needed to produce the desired drug response. Some patients respond to a lower drug dose, whereas others need a high drug dose to elicit the desired response. The drug dose is usually adjusted to achieve the desired drug response.

All drugs have a maximum drug effect (maximal efficacy). For example, morphine and tramadol hydrochloride (Ultram) are prescribed to relieve pain. The maximum efficacy of morphine is greater than tramadol hydrochloride, regardless of how much tramadol hydrochloride is given. The pain relief with the use of tramadol hydrochloride is not as great as it is with morphine.

Onset, Peak, and Duration of Action

One important aspect of pharmacodynamics is knowing the drug's onset, peak, and duration of action. **Onset of action** is the time it takes to reach the minimum effective concentration (MEC) after a drug is administered. **Peak action** occurs when the drug reaches its highest blood or plasma concentration. **Duration of action** is the length of time the drug has a pharmacologic effect. Figure 1-6 illustrates the areas in which onset, peak, and duration of action occur.

Some drugs produce effects in minutes, but others may take hours or days. A **time-response curve** evaluates three parameters of drug action: the onset of drug action, peak action, and duration of action. Figure 1-6 indicates these parameters by using T (time) with subscripts (e.g., T_0, T_1, T_2, T_3).

It is necessary to understand the time response in relationship to drug administration. If the drug plasma or serum level decreases below threshold or MEC, adequate drug dosing is

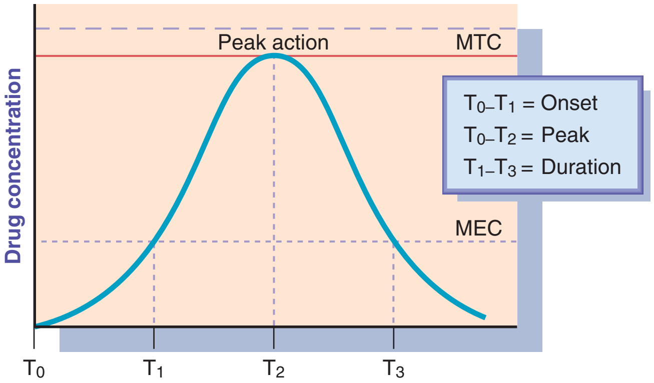

FIGURE 1–6 The time-response curve evaluates three parameters of drug action: (1) onset, (2) peak, and (3) duration. *MEC,* Minimum effective concentration; *MTC,* minimum toxic concentration.

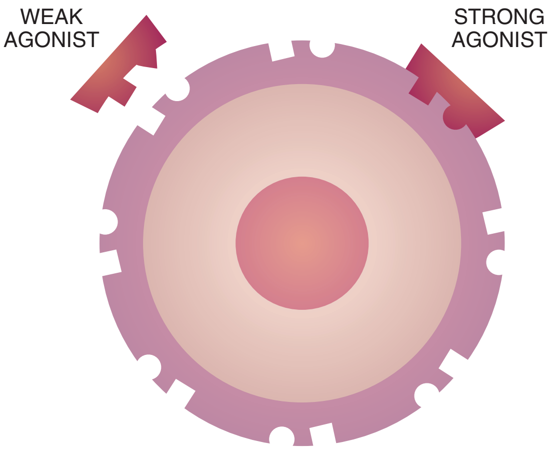

FIGURE 1–7 Two drug agonists attach to the receptor site. The drug agonist that has an exact fit is a strong agonist and is more biologically active than the weak agonist.

not achieved; too high a drug level above the minimum toxic concentration (MTC) can result in toxicity.

Receptor Theory

Drugs act through receptors by binding to the receptor to produce (initiate) a response or to block (prevent) a response. The activity of many drugs is determined by the ability of the drug to bind to a specific receptor. The better the drug fits at the receptor site, the more biologically active the drug is. It is similar to the fit of the right key in a lock. Figure 1-7 illustrates a drug binding to a receptor.

Most receptors, which are protein in nature, are found in cell membranes. Drug-binding sites are primarily on proteins, glycoproteins, proteolipids, and enzymes. There are four **receptor families:** (1) kinase-linked receptors, (2) ligand-gated ion channels, (3) G protein–coupled receptor systems, and (4) nuclear receptors. The **ligand-binding domain** is the site on the receptor at which drugs bind.

- *Kinase-linked receptors.* The ligand-binding domain for drug binding is on the cell surface. The drug activates the enzyme (inside the cell), and a response is initiated.
- *Ligand-gated ion channels.* The channel spans the cell membrane and, with this type of receptor, the channel opens, allowing for the flow of ions into and out of the cells. The ions are primarily sodium and calcium.
- *G protein–coupled receptor systems.* There are three components to this receptor response: (1) the receptor, (2) the G protein that binds with guanosine triphosphate (GTP), and (3) the effector that is either an enzyme or an ion channel. The system works as follows:

$$\text{drug} \xrightarrow{\text{activates}} \text{receptors} \xrightarrow{\text{activates}} \text{G protein} \xrightarrow{\text{activates}} \text{effect}$$

- *Nuclear receptors.* Found in the cell nucleus (not on the surface) of the cell membrane. Activation of receptors through the transcription factors is prolonged. With the first three receptor groups, activation of the receptors is rapid.

Agonists and Antagonists

Drugs that produce a response are called **agonists,** and drugs that block a response are called **antagonists.** Epinephrine (Adrenalin) stimulates beta$_1$ and beta$_2$ receptors, so it is an agonist. Atropine, an antagonist, blocks the histamine (H_2) receptor, thus preventing excessive gastric acid secretion. The effects of an antagonist can be determined by the inhibitory (I) action of the drug concentration on the receptor site. IC_{50} is the antagonist drug concentration required to inhibit 50% of the maximum biological response.

Nonspecific and Nonselective Drug Effects

Many agonists and antagonists lack specific and selective effects. A receptor produces a variety of physiologic responses, depending on where in the body the receptor is located. Cholinergic receptors are located in the bladder, heart, blood vessels, stomach, bronchi, and eyes. A drug that stimulates or blocks the cholinergic receptors affects all anatomic sites of location. Drugs that affect various sites are **nonspecific drugs** and have properties of nonspecificity. Bethanechol (Urecholine) may be prescribed for postoperative urinary retention to increase bladder contraction. This drug stimulates the cholinergic receptor located in the bladder, and urination occurs by strengthening bladder contraction. Because bethanechol affects the cholinergic receptor, other cholinergic sites are also affected. The heart rate decreases, blood pressure decreases, gastric acid secretion increases, the bronchioles constrict, and the pupils of the eye constrict (Figure 1-8). These other effects may be either desirable or harmful. Drugs that evoke a variety of responses throughout the body have a nonspecific response.

Drugs may act at different receptors. Drugs that affect various receptors are **nonselective drugs** or have properties of nonselectivity. Chlorpromazine (Thorazine) acts on the norepinephrine, dopamine, acetylcholine, and histamine receptors, and a variety of responses result from action at these receptor sites. Epinephrine acts on the alpha$_1$, beta$_1$, and beta$_2$ receptors (Figure 1-9). Drugs that produce a response but do not act on a receptor may act by stimulating or inhibiting enzyme activity or hormone production.

Categories of Drug Action

The four categories of drug action include (1) stimulation or depression, (2) replacement, (3) inhibition or killing of organisms, and (4) irritation. In drug action that stimulates, the rate of cell activity or the secretion from a gland increases. In drug action that depresses, cell activity and function of a specific organ are reduced. Replacement drugs such as insulin replace essential body compounds. Drugs that inhibit or kill organisms interfere with bacterial cell growth (e.g., penicillin exerts its bactericidal effects by blocking the synthesis of the bacterial cell wall). Drugs also can act by the mechanism of irritation (e.g., laxatives irritate the inner wall of the colon, thus increasing peristalsis and defecation).

Therapeutic Index and Therapeutic Range (Therapeutic Window)

The safety of drugs is a major concern. The **therapeutic index (TI)** estimates the margin of safety of a drug through the use of a ratio that measures the effective (therapeutic) dose (ED) in 50% of people (ED_{50}) and the lethal dose (LD) in 50% of people (LD_{50}) (Figure 1-10). The closer the ratio is to 1, the greater the danger of toxicity.

$$TI = \frac{LD_{50}}{ED_{50}}$$

In some cases, the ED may be 25% (ED_{25}) or 75% (ED_{75}).

Drugs with a low therapeutic index have a narrow margin of safety (Figure 1-11, *A*). Drug dosage might need adjustment, and plasma (serum) drug levels need to be monitored because of the small safety range between the ED and LD. Drugs with a high therapeutic index have a wide margin of safety and less danger of producing toxic effects (Figure 1-11, *B*). Plasma (serum) drug levels do not need to be monitored routinely for drugs with a high TI.

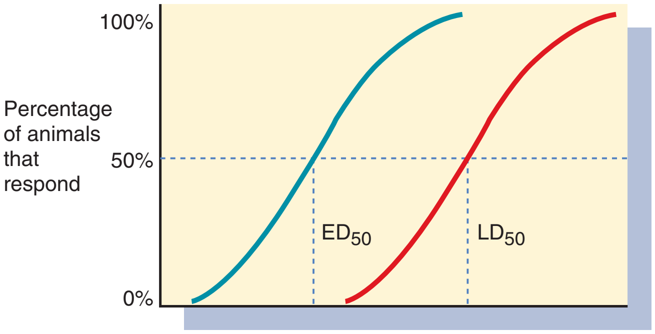

FIGURE 1–10 The therapeutic index measures the margin of safety of a drug. It is a ratio that measures the effective therapeutic dose and the lethal dose.

The **therapeutic range (therapeutic window)** of a drug concentration in plasma is the level of drug between the minimum effective concentration in the plasma for obtaining desired drug action and the minimum toxic concentration (the toxic effect). When the therapeutic range is given, it includes both protein-bound and unbound portions of the drug. If the therapeutic range is narrow, such as for digoxin (0.5 to 1 ng/mL), the plasma drug level should be monitored periodically to avoid drug toxicity. Monitoring the therapeutic range is not necessary if the drug is not considered highly toxic. When the therapeutic range is given, it includes both protein-bound and unbound portions of the drug. Table 1-3 lists the therapeutic ranges and toxic levels for anticonvulsants.

Peak and Trough Drug Levels

Peak drug levels indicate the rate of absorption of the drug, and trough drug levels indicate the rate of elimination of the drug. Peak and trough levels are requested for drugs that have a narrow therapeutic index and are considered toxic, such as the aminoglycoside antibiotics (Table 1-4). If either the peak or trough level is too high, toxicity can occur. If the peak is too low, no therapeutic effect is achieved. **Peak drug level** is the highest plasma concentration of drug at a specific time. Peak drug levels indicate the rate of absorption. If the drug is given orally, the peak time might be 1 to 3 hours after drug administration. If the drug is given IV, the peak time might occur in 10 minutes. If a peak drug level is ordered, a blood sample should be drawn at the proposed peak time, according to the route of administration.

The **trough drug level** is the lowest plasma concentration of a drug, and it measures the rate at which the drug is eliminated. Trough levels are drawn immediately before the next dose of drug is given, regardless of route of administration.

TABLE 1-3 ANTICONVULSANTS: THERAPEUTIC RANGES AND TOXIC LEVELS

DRUG	THERAPEUTIC RANGE (mcg/mL)	TOXIC LEVEL (mcg/mL)
carbamazepine	6-12	>12-15
ethosuximide	40-80	>80-100
phenytoin	10-20	>30
primidone	5-10	>12-15
valproic acid	50-150	>150

>, Greater than.

Loading Dose

When immediate drug response is desired, a large initial dose, known as the **loading dose,** of drug is given to achieve a rapid minimum effective concentration in the plasma. After a large initial dose, a prescribed dosage per day is ordered. Digoxin (Digitek, Lanoxicaps, Lanoxin), a digitalis preparation, requires a loading dose when first prescribed. Digitalization is the process by which the minimum effective concentration level for digoxin is achieved in the plasma within a short time.

Side Effects, Adverse Reactions, and Toxic Effects

Side effects are physiologic effects not related to desired drug effects. All drugs have desirable or undesirable side effects. Even with a correct drug dosage, side effects occur and are predicted. Side effects result mostly from drugs that lack specificity, such as bethanechol (Urecholine). In some health problems, side effects may be desirable (e.g., the use of diphenhydramine HCl [Benadryl] at bedtime when its side effect of drowsiness is beneficial). At times, however, side

TABLE 1-4 AMINOGLYCOSIDE ANTIBIOTICS: PEAK AND TROUGH LEVELS

DRUG	PEAK (mcg/mL)	TROUGH (mcg/mL)	TOXIC PEAK LEVEL (mcg/mL)	TOXIC TROUGH LEVEL (mcg/mL)
amikacin	15-30	5-10	>35	>10
gentamicin	5-10	<2	>12	>2
tobramycin	5-10	<2	>12	>2

>, Greater than; <, less than.

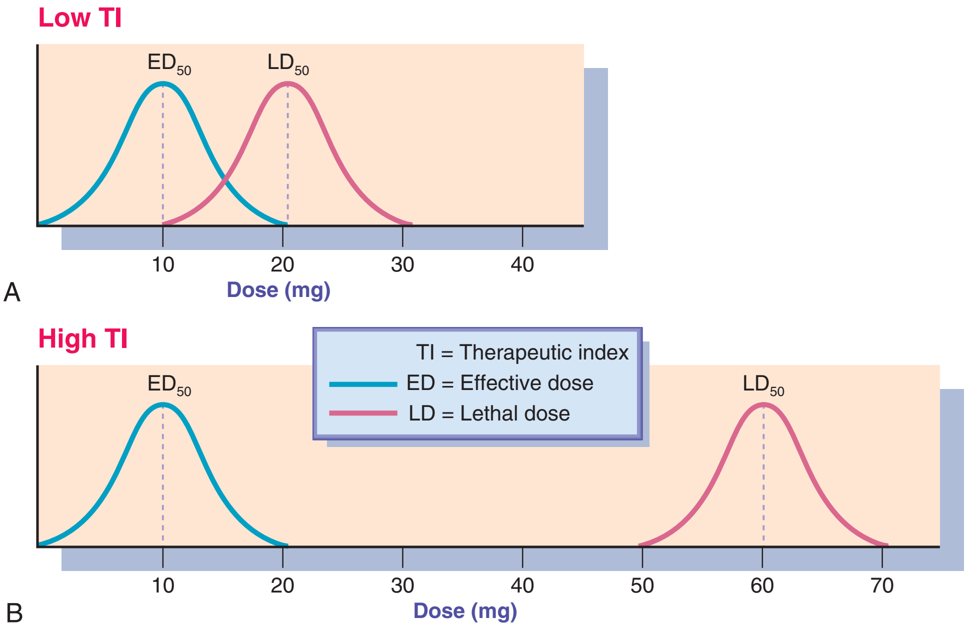

FIGURE 1–11 **A,** Low therapeutic index drug has a narrow margin of safety, and the drug effect should be closely monitored. **B,** High therapeutic index drug has a wide margin of safety and carries less risk of drug toxicity.

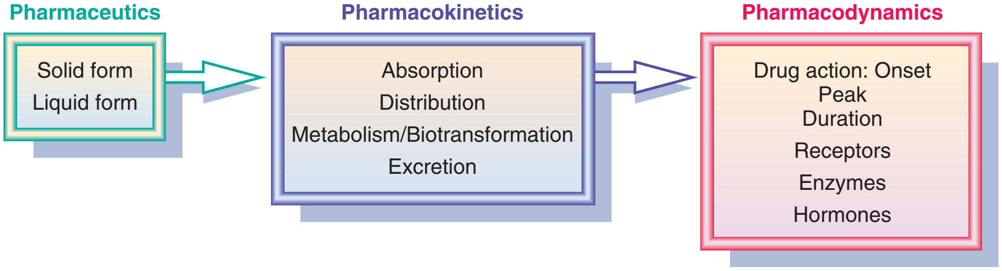

FIGURE 1–12 The three phases of drug action.

effects are called *adverse reactions.* The terms *side effects* and *adverse reactions* are sometimes used interchangeably in the literature and in speaking, but they are different. Some side effects are expected as part of drug therapy. The occurrence of these expected but undesirable side effects is not a reason to discontinue therapy. The nurse's role includes teaching patients to report any side effects. Many can be managed with dosage adjustments, changing to a different drug in the same class of drugs, or implementing other interventions. It is important to know that the occurrence of side effects is one of the primary reasons patients stop taking the prescribed medication. **Adverse reactions** are more severe than side effects. They are a range of untoward effects (unintended and occurring at normal doses) of drugs that cause mild to severe side effects, including anaphylaxis (cardiovascular collapse). Adverse reactions are always undesirable. Adverse effects must always be reported and documented because they represent variances from planned therapy.

Toxic effects, or **toxicity,** of a drug can be identified by monitoring the plasma (serum) therapeutic range of the drug. However, for drugs that have a wide therapeutic index, the therapeutic ranges are seldom given. For drugs with a narrow therapeutic index, such as aminoglycoside antibiotics and anticonvulsants, the therapeutic ranges are closely monitored. When the drug level exceeds the therapeutic range, toxic effects are likely to occur from overdosing or drug accumulation.

Pharmacogenetics

Pharmacogenetics is the scientific discipline studying how the effect of a drug action varies from a predicted drug response because of genetic factors or hereditary influence. Because people have different genetic makeup, they do not always respond identically to a drug dosage or planned drug therapy. Genetic factors can alter the metabolism of the drug in converting its chemical form to an inert metabolite; thus, the drug action can be enhanced or diminished. Some persons are less or more sensitive to drugs and their drug actions because of genetic factors. For example, African Americans do not respond as well as Caucasians to some classes of antihypertensive medications such as ACE inhibitors. (See Chapter 3 for a discussion of pharmacogenetics.)

Tolerance and Tachyphylaxis

Tolerance refers to a decreased responsiveness over the course of therapy. In contrast, **tachyphylaxis** refers to a rapid decrease in response to the drug. In essence, tachyphylaxis is an "acute tolerance." Drug categories that can cause tachyphylaxis include narcotics, barbiturates, laxatives, and psychotropic agents. For example, drug tolerance to narcotics can result in decreased pain relief for the patient. If the nurse does not recognize the development of drug tolerance, the patient's request for more pain medication might be interpreted as drug-seeking behavior associated with addiction. Prevention of tachyphylaxis should always be part of the therapeutic regimen (see Chapter 42).

Placebo Effect

A **placebo effect** is a psychological benefit from a compound that may not have the chemical structure of a drug effect. The placebo is effective in approximately one third of persons who take a placebo compound. Many clinical drug studies involve a group of subjects who receive a placebo. The nurse can increase the therapeutic effect of the drug (e.g., narcotics for pain management) but violate the truth-telling ethical principle if a nontherapeutic drug is presented as a therapeutic agent. Hence, it is required that participants in drug trials be told from the start that they might receive a placebo.

To review, the phases of drug action are pharmaceutic, pharmacokinetic, and pharmacodynamic. Figure 1-12 illustrates these three phases for drugs given orally, but drugs given by injection are involved only in the pharmacokinetic and pharmacodynamic phases. Nurses should be aware that tablets must disintegrate and go into solution (the pharmaceutic phase) to be absorbed.

To avoid toxic effects, the nurse must know the half-life, protein-binding percentage, normal side effects, and therapeutic ranges of the drug. This information can be obtained from drug reference books.

Nursing Process

Patient-Centered Collaborative Care

Assessment

- Take patient history to identify factors that may affect drug pharmacokinetics (e.g., gastric surgery will affect absorption; low serum albumin will affect protein binding; peripheral vascular disease may affect drug distribution to extremities).

- Examine the patient's history to identify factors that may affect pharmacodynamics (e.g., a G6PD deficiency may cause hemolytic anemia if some common drugs are given)
- Collect a medication history.
- Perform a physical exam to identify problems that may affect pharmacodynamics (e.g., elevated BP, dysrhythmias, or other abnormal findings may be an indication for drug therapy).
- Identify side effects of drugs that are nonspecific (same receptor at different tissue and organ sites). For example, when atropine is the drug to be administered, assess for tachycardia, dry mouth and throat, constipation, urinary retention, and blurred vision. If nonspecific drugs are given in large doses or at frequent intervals, many side effects are likely to occur.
- Check peak levels and trough levels of drugs such as aminoglycosides that have a narrow therapeutic range. If the trough level is high, toxic effects can result.
- Check the drug literature for the protein-binding percentage of the drug. Drugs with a high protein-binding effect have a large portion of drug bound to protein. This causes the drug to become inactive until it is released from the protein. The portion not bound to protein is a free and active drug.

Nursing Interventions

- Advise patient not to eat high-fat food before ingesting an enteric-coated tablet, because high-fat foods decrease absorption rate.
- Report to the health care provider if drugs with a long half-life (i.e., greater than 24 hours) are given more than once a day. Some drugs with a long half-life (e.g., the anticoagulant warfarin [Coumadin]) can be more dangerous than others and must be monitored frequently.
- Monitor the therapeutic range of drugs that are more toxic or have a narrow therapeutic range (e.g., digoxin).

Cultural Considerations

- Be aware that individuals of some ethnic or racial heritage metabolize drugs differently than the general population.
- Assess for adverse effects that may result from this variation in metabolism.

Evaluation

- Evaluate the determinants that affect drug therapy according to Figure 1-13.
- Assess for signs and symptoms of drug toxicity when giving two drugs that are highly protein-bound. The drugs compete for protein-binding sites, and displacement of drugs occurs. More free drug is in circulation because there are not enough protein-binding sites. Too much of a free drug can result in drug toxicity.

CRITICAL THINKING CASE STUDY

The nurse is caring for JM, a patient who was admitted to the hospital with new onset of seizures. JM has been taking warfarin (Coumadin), a highly protein-bound drug that decreases blood clotting. The neurologist has ordered valproic acid (Depakote), an antiseizure medication. Valproic acid is also highly protein bound.

1. What information needs to be included in the interdisciplinary health/teaching plan for this patient?

NCLEX STUDY QUESTIONS

1. Which components of pharmacokinetics does the nurse need to understand before administering a drug? (Select all that apply.)
   - a. Drugs with a smaller volume of drug distribution have a longer half-life.
   - b. Oral drugs are dissolved through the process of pinocytosis.
   - c. Patients with kidney disease may have fewer protein-binding sites and are at risk for drug toxicity.
   - d. Rapid absorption decreases the bioavailability of the drug.
   - e. When the drug metabolism rate is decreased, excess drug accumulation can occur, which can cause toxicity.
2. The nurse will question the health care provider if a drug with a half-life (t½) of more than 24 hours is ordered to be given more than how often?
   - a. Once daily
   - b. Every other day
   - c. Twice weekly
   - d. Once weekly
3. The nurse is explaining drug action to a nursing student. Which statement made by the nurse is correct?
   - a. "Water-soluble and ionized drugs are quickly absorbed."
   - b. "A drug not bound to protein is an active drug."
   - c. "Most receptors are found under the cell membrane."
   - d. "Toxic effects can result if the trough level is low."
4. The nurse is caring for a patient with congestive heart failure who is receiving digoxin (Digitek, Lanoxicaps, Lanoxin). The nurse plans to take which action when administering digoxin?
   - a. Check the peak levels of digoxin.
   - b. Check the trough levels digoxin.
   - c. Monitor for tachyphylaxis.
   - d. Monitor the therapeutic range of digoxin.
5. The nurse anticipates that the health care provider will order which laboratory test for an older adult with renal dysfunction?
   - a. Creatinine clearance
   - b. Glomerular filtration rate
   - c. Urine specific gravity
   - d. Urine pH
6. When reviewing the patient's medication regimen, the nurse understands that the interval of drug dosage is related to what?
   - a. Half-life
   - b. Stimulation of receptors
   - c. Therapeutic index
   - d. Trough level
7. Which nursing assessment(s) will the nurse include when developing a patient medication plan? (Select all that apply.)
   - a. Check peak and trough levels of drugs.
   - b. Check the drug literature for the protein-binding percentage of a drug.
   - c. Identify side effects of drugs that are nonspecific.
   - d. Evaluate the patient's reaction to a drug.
   - e. To enhance absorption, advise the patient to crush an enteric-coated tablet before taking.
8. A student nurse is studying the phases of drug action. Which statement by the student indicates to the nursing instructor that the student understands the pharmaceutic phase?
   - a. "To achieve drug action, drugs are moved by four processes."
   - b. "For the drug to cross the biologic membrane, the drug becomes a solution."
   - c. "In this phase, drugs are concentrated and a biologic or physiologic response occurs."
   - d. "The pharmaceutic phase is the process by which the drug becomes available to body fluids and tissue."
9. The nurse plans to advise the patient to avoid which food(s) before ingesting an enteric-coated medication? (Select all that apply.)
   - a. Bananas
   - b. Baked lamb chops
   - c. Broiled fish
   - d. Ice cream
   - e. Fried chicken

Answers: 1, c, e; 2, a; 3, b; 4, d; 5, a; 6, a; 7, a, b, c; 8, b; 9, d, e.

CHAPTER 2

The Drug Approval Process

- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Discuss the federal legislation acts related to U.S. Food and Drug Administration drug approvals.
- Explain the Canadian schedules for drugs sold in Canada.
- Describe the function of nurse practice acts.
- Differentiate between chemical, generic, and brand names of drugs.
- Describe useful drug references.

Approval of new drugs by the **U.S. Food and Drug Administration** (FDA) has been steady since the early 2000s; the FDA's Center for Drug Evaluation and Research (CDER) has averaged 23 approvals per year. In 2004, the FDA established its Critical Path Initiative, a national strategy "to drive innovation in the scientific processes through which medical products are developed, evaluated, and manufactured." One focus is on "improving the prevention, diagnosis, and treatment of rare and neglected disorders." Successes of the initiative include developing biomarkers and other scientific tools, streamlining clinical trials, and ensuring product safety.

DRUG STANDARDS AND LEGISLATION

The combination of drug discovery and manufacturing takes 12 to 20 years, with a cost of more than $1 billion. Only a small percentage of drugs are approved. The steps of the process are shown in Figure 2-1.

Drug Standards

The set of drug standards used in the United States is the *United States Pharmacopeia* of 1820. The ***United States Pharmacopeia National Formulary (USP-NF),*** the current three-volume authoritative source for drug standards, is an annual

publication with two supplements. Experts in nursing, pharmaceutics, pharmacology, chemistry, and microbiology all contribute. Drugs included in the *USP-NF* have met high standards for therapeutic use, patient safety, quality, purity, strength, packaging safety, and dosage form. Drugs that meet these standards have the initials "USP" following their official name, denoting global recognition of high quality. The *USP-NF* is the official publication for drugs marketed in the United States, so designated by the U.S. Federal Food, Drug, and Cosmetic Act.

The *International Pharmacopeia,* first published in 1951 by the World Health Organization (WHO), provides a basis for standards in strength and composition of drugs for use throughout the world. The book is published in English, Spanish, and French. The fourth edition (Volumes I and II) was published in 2006, with the first supplement in 2008.

Federal Legislation

Through federal legislation, the public is protected from drugs that are impure, toxic, ineffective, or not tested before public sale. The primary purpose of the legislation is to ensure safety. America's first law to regulate drugs was the Federal Pure Food and Drug Act of 1906, which did not include drug effectiveness and drug safety.

1938: Food, Drug, and Cosmetic Act

The Food, Drug, and Cosmetic Act of 1938 empowered the FDA to ensure drug safety by monitoring and regulating the manufacture and marketing of drugs. It is the FDA's responsibility to ensure that all drugs are tested for harmful effects, have labels with accurate information, and enclose detailed literature in the drug packaging that explains adverse effects. The FDA can prevent the marketing of any drug it judges to be incompletely tested or dangerous. Only drugs considered safe by the FDA are approved for marketing.

1952: Durham-Humphrey Amendment to the 1938 Act

The Durham-Humphrey Amendment to the Food, Drug, and Cosmetic Act of 1938 distinguished between drugs that can be sold with or without prescription and those that should not be refilled without a new prescription. Those drugs that should not be refilled without a new prescription, such as narcotics, hypnotics, or tranquilizers, must be so labeled.

1962: Kefauver-Harris Amendment to the 1938 Act

The Kefauver-Harris Amendment to the Food, Drug, and Cosmetic Act of 1938 resulted from the widely publicized thalidomide tragedy of the 1950s in which European patients who took the sedative-hypnotic thalidomide during the first trimester of pregnancy gave birth to infants with extreme limb deformities. The Kefauver-Harris amendment tightened controls on drug safety, especially experimental drugs, and required that adverse reactions and contraindications must be labeled and included in the literature. The amendment also included provisions for the evaluation of testing methods used by manufacturers, the process for withdrawal of approved drugs when safety and effectiveness were in doubt, and the establishment of effectiveness of new drugs before marketing.

1970: The Controlled Substances Act

In 1970, Congress passed the Controlled Substances Act (CSA) of the Comprehensive Drug Abuse Prevention and Control Act, Title II. This act, designed to remedy the escalating problem of drug abuse, included several provisions: (1) promotion of drug education and research into the prevention and treatment of drug dependence; (2) strengthening of enforcement authority; (3) establishment of treatment and rehabilitation facilities; and (4) designation of schedules, or categories, for controlled substances according to abuse liability.

Controlled substances are described in five schedules, or categories, and are listed in Table 2-1. Schedule I drugs are not approved for medical use; schedule II through V drugs have accepted medical use. In addition, the abuse potential and extent of physical and psychological dependence are greatest with schedule I drugs. This dependency decreases as one moves through the schedule, with schedule V drugs having only limited abuse potential. Some drugs might be listed in more than one schedule category. Codeine is a schedule II drug, but when it is added to acetaminophen, it becomes a schedule III drug, and when it is used in combination as a cough preparation, it becomes a schedule V drug.

Nursing interventions for controlled substances are as follows:

- Account for all controlled drugs.
- Keep a special controlled-substance record for required information.
- Countersign all discarded or wasted medication; wastage must be witnessed.
- Ensure that documentation and drugs on hand match.
- Keep all controlled drugs in a locked storage area; keep narcotics under double lock. Be certain that only authorized persons have access to the keys, including keys for patient-controlled analgesia and epidural pumps. Medication may also be administered via an automated dispensing cabinet, with bioidentical identifiers used for access.
- The American Nurses Association (ANA) recognizes nurse drug diversion and recommends that all states have a peer-to-peer assistance program for addicted nurses. Reporting is mandatory if suspected or known diversion occurs.

1978: Drug Regulation Reform Act

This act shortened the time in which new drugs could be developed and marketed. It protects patients' rights and at the same time facilitates the investigational process and promotes research.

1983: The Drug Enforcement Administration and the Orphan Drug Act

In 1983, the **Drug Enforcement Administration** (DEA) of the Department of Justice was charged with the role of being the nation's sole legal drug enforcement agency. In the same year, the Orphan Drug Act was designed to promote the development and manufacture of orphan drugs, those drugs used in the treatment of rare diseases. The act's three primary incentives are (1) federal funding of grants and contracts to perform clinical trials of orphan products; (2) 50% tax credit for costs of clinical testing; and (3) exclusive right to market the drug for 7 years from the marketing approval date.

1997: The Food and Drug Administration Modernization Act

The five provisions in this act are (1) review and use of new drugs is accelerated; (2) drugs can be tested in children before marketing; (3) clinical trial data are necessary for experimental drug use for serious or life-threatening health conditions; (4) drug companies are required to give information on "off-label" drugs (non–FDA-approved drugs) and their uses and costs; and (5) drug companies that plan to discontinue drugs must inform health professionals and patients at least 6 months before stopping drug production.

TABLE 2-1 SCHEDULE CATEGORIES OF CONTROLLED SUBSTANCES

SCHEDULE	EXAMPLES OF SUBSTANCES	DESCRIPTION
I	Heroin, hallucinogens (LSD, marijuana [except when prescribed with cancer treatment], mescaline, peyote, psilocybin)	High potential for drug abuse. No accepted medical use. Labeled C-I.
II	Meperidine (Demerol), morphine, hydrocodone (Hycodan), hydromorphone (Dilaudid), methadone (Dolophine), oxycodone (Oxy-Contin), codeine, amphetamines, secobarbital, pentobarbital (Nembutal)	High potential for drug abuse. Accepted medical use. Can lead to strong physical and psychological dependency. Labeled C-II.
III	Codeine preparations, paregoric, nonnarcotic drugs (e.g., pentazocine [Talwin])	Medically accepted drugs. Potential abuse is less than that for schedules I and II. May cause dependence. Labeled C-III.
IV	Phenobarbital (Luminal), benzodiazepines (e.g., diazepam [Valium], oxazepam [Serax], lorazepam [Ativan], chlordiazepoxide [Librium]), chloral hydrate (Aquachloral), meprobamate	Medically accepted drugs. May cause dependence. Labeled C-IV.
V	Opioid-controlled substances for diarrhea and cough (e.g., codeine in cough preparations)	Medically accepted drugs. Very limited potential for dependence. Labeled C-V.

C, Control; *LSD,* lysergic acid diethylamide.

2002: Best Pharmaceuticals for Children Act

This act gives manufacturers extension of patents to evaluate drugs on the market for their safety and efficacy in children.

2003: Health Insurance Portability and Accountability Act

The Health Insurance Portability and Accountability Act (HIPAA) of 2003 set the standards for the privacy of individually identifiable health information. This rule gives patients more control over their health information, including boundaries on the use and release of health records. Implications of HIPAA related to the individual's therapeutic regimen include limitation on access to information from the pharmacy. For example, patient history can be released only to the patient, and the pharmacist must provide a private area for consultation and have all patients sign a statement that they have received a copy of the privacy statement.

2003: Pediatric Research Equity Act

This act authorizes the FDA to require that drug manufacturers test drugs and biologic products for their safety and effectiveness in children, noting that "children are not small adults."

2007: Food and Drug Administration Amendments Act

This act allows the FDA to mandate postmarketing safety studies and to affect the distribution of drugs that are found to be not as safe as premarket studies indicated.

2009: Family Smoking Prevention and Tobacco Control Act

This act allows the FDA to regulate cigarettes by various measures such as requiring prominent warning labels and complete ingredient lists and prohibiting youth marketing.

2010: Patient Protection and Affordable Care Act

This act was signed into law in 2010 but will not be fully executed until 2014. Essential components of the reform include (1) quality, affordable health care for all Americans; (2) improved quality and efficiency of health care; (3) prevention of chronic disease and improved public health; (4) improved access to innovative medical therapies; and (5) community living services and supports.

NURSE PRACTICE ACTS

Every state has its own laws regarding drug administration by nurses. Generally, nurses cannot prescribe or administer drugs without a health care provider's order. Practicing nurses should be knowledgeable about the nurse practice act in the state where they are licensed. (Nurse practice acts are available online.) Nurses are responsible for knowing their state's law and administrative code. Nurses who administer a drug without a licensed health care provider's order are in violation of the nurse practice act and can have their licenses revoked.

In a civil court, the nurse can be prosecuted for giving the wrong drug or dosage, omitting a drug dose, or giving the drug by the wrong route. The legal terms for these offenses are as follows:

- ***Misfeasance.*** Negligence; giving the wrong drug or drug dose that results in the patient's death
- ***Nonfeasance.*** Omission; omitting a drug dose that results in the patient's death
- ***Malfeasance.*** Giving the correct drug but by the wrong route that results in the patient's death

CANADIAN DRUG REGULATION

In Canada, the Health Protection Branch, Department of National Health and Welfare, is responsible for the administration of the two acts that are the foundation of national drug laws. The manufacture, distribution, and sale of drugs (except narcotics) are controlled by the Canadian Food and Drug Act, which was amended in 1953. The manufacture, distribution, and sale of narcotic drugs are controlled by the 1996 Controlled Drugs and Substances Act (CDSA). Like the U.S. Controlled Substances Act, the Canadian act requires prescriptions and strict recordkeeping for all narcotics.

Drugs sold in Canada are assigned to one of the following schedules:

1. *Schedule F Prescription Drugs.* All prescription drugs, except narcotics and controlled substances, are available only by prescription (written or verbal); thus, these drugs have essentially no potential for abuse. Manufacturing labels are required to include Pr.
2. The CDSA regulates the control and sale of narcotics and controlled substances through identification of eight schedules based on potential for abuse. Recordkeeping and degree of control are specified for each. Labels must include a C for controlled agents and an N for narcotic agents. Benzodiazepines are "targeted substances," with *t/c* on all labels. The schedules are as follows:
   1. *Schedule I*: Opium poppy and its derivatives (e.g., morphine, heroin); methadone; coca and its derivates (e.g., cocaine)
   2. *Schedule II*: Cannabis and its derivatives (e.g., marijuana, hashish)
   3. *Schedule III*: Amphetamines, methylphenidate, lysergic acid diethylamide (LSD), methaqualone, psilocybin, mescaline
   4. *Schedule IV*: Sedative-hypnotic agents (e.g., barbiturates, benzodiazepines); anabolic steroids
   5. Schedules V through VIII are in development.

The CDSA covers select codeine preparations. Low-dose codeine (20 mg/30 mL and 8-mg tablets) is an exception and can be sold only by a pharmacist. Two additional medicinal ingredients (usually caffeine and acetylsalicylic acid) must be part of this codeine preparation.

Nonprescription drugs are administered by the pharmacy acts of the respective Canadian provinces that identify the place and conditions of sale. These drugs are assigned to one of three categories:

1. *Nonprescription drugs sold at any retailer.* There is no requirement for professional supervision. Labeling provides information for the patient to make an informed choice for safe use. An example of this category is antiulcer medications.
2. *Pharmacy-only nonprescription drugs.* A pharmacist must be available for advice. The patient self-selects a medication that may have risks for certain populations. An example of this category is antihistamines.
3. *Restricted access nonprescription drugs.* These are available only from the pharmacist. Consultation with a pharmacist is required, and referral to a health care provider is supplied if necessary. An example of this category is insulin.

To address the proliferation of a variety of provincial schedules and regulations, the National Association of Pharmacy Regulatory Authorities (NAPRA) has proposed to "harmonize" regulations nationwide by creating three national drug schedules using the same nomenclature and numbering as the controlled substances schedule system. The NAPRA website at *www.napra.ca* provides detailed information on this system. The schedules are as follows:

1. *Schedule I:* All prescription drugs, including narcotics and controlled substances
2. *Schedule II:* Restricted access of pharmacist-only nonprescription drugs
3. *Schedule III:* Pharmacy-only nonprescription drugs
4. *Unscheduled Drugs:* Drugs that are available at retail outlets and not placed in the above categories

In Canada, therapeutic and toxic levels are monitored according to the International System of Units (SI); this is also true in many European countries. The mole (mol) was adopted to express drug concentration in body fluid in molar units, such as millimoles per liter (mmol/L), instead of the traditional expression of mass units, milligrams per liter (mg/L). Some institutions in the United States use SI units, but the traditional use of mass units in the United States continues.

INITIATIVES TO COMBAT DRUG COUNTERFEITING

Use of counterfeit and adulterated prescription drugs is on the rise. Contributing reasons are that reporting of counterfeit incidents is not mandatory and that counterfeiting has features of a "perfect crime" (medicine is taken; evidence is gone). (See Chapter 12.) The FDA and consumer groups are working on strategies to combat this problem, including tougher oversight of distributors, a rapid alert system, and better-informed consumers. The role of the nurse is critical in consumer education. The nurse must advise patients to report any differences in taste or appearance of a drug or in its packaging. Patients should be alert to slight variations in packaging or labeling (e.g., color, package seal); should note any unexpected side effects; and should buy drugs from reputable sources. Reputable online pharmacies have the designation of Verified Internet Pharmacy Practice Site (VIPPS) and display an approval seal. If any suspicion of counterfeit arises, the patient, family, or nurse should contact the FDA at *www.fda.gov/Safety/MedWatch/HowToReport/*.

DRUG NAMES

Drugs have several names. The **chemical name** describes the drug's chemical structure. The **generic name** is the official, nonproprietary name for the drug. This name is not owned by any drug company and is universally accepted. Most drugs are ordered by generic name. The **brand (trade) name,** also known as the *proprietary name,* is chosen by the drug company and is usually a registered trademark owned by that specific company. Drug companies market a compound using its brand name. For example, Narcan is the brand (proprietary) name of a drug whose generic name is naloxone HCl.

Throughout this text, both generic and brand names are given for each drug at its first mention. Because many brand names may exist for a single generic name, the generic name is given first in lowercase letters, followed by the most commonly used brand name in parentheses. Brand names always begin with a capital letter. An example of a generic and brand-name drug listing is "furosemide (Lasix)."

Generic drugs must be approved by the FDA before they can be marketed. If the generic drug is found to be bioequivalent to the brand-name drug, then the generic drug is considered therapeutically equivalent and is given an "A" rating. If the peak serum concentration and the plasma-concentration curve of the generic drug fall within 80% to 125% of the brand-name drug, then the generic drug is considered equivalent to the brand-name drug.

Approved generic drugs can be checked at *www.accessdata.fda.gov/scripts/cder/drugsatfda/*. The FDA also publishes a list of approved generic drugs that are bioequivalent to brand-name drugs. Generic drugs have the same active ingredients as brand-name drugs but are usually less expensive because manufacturers do not have to do extensive testing; these drugs were clinically tested for safety and efficacy by the pharmaceutic company that first formulated the drug. However, some generic drugs have inert fillers and binders that may result in variations of drug effectiveness.

The health care provider and the patient must exercise care in choosing generic drugs because of possible variation in their action or the response to them. Brand-name drugs are preferred when ordering anticonvulsants for seizures; anticoagulants (e.g., Coumadin); medication for heart failure (e.g., Lanoxin); and aspirin in large doses for rheumatoid arthritis. The nurse should check with the health care provider or the pharmacist when generic drugs are prescribed. The health care provider must note on the prescription whether the pharmacist may substitute the generic drug when the brand name is prescribed.

DRUG RESOURCES

Many drug references are available, including nursing texts that identify related nursing interventions and areas for health teaching. Some recommended resources follow.

American Hospital Formulary Service (AHFS) Drug Information is published by the American Society of Health-System Pharmacists in Bethesda, Maryland. It provides accurate and complete drug information on nearly all prescription drugs marketed in the United States. This text contains drugs listed according to therapeutic drug classification. The information given for each drug includes chemistry and stability, pharmacologic actions, pharmacokinetics, uses, cautions per body system, precautions, contraindications, acute toxicity, drug interactions, dosage and administration, and preparations.

This reference is updated yearly with monthly supplements. The supplements contain information on new drugs such as dosage forms and strengths, uses, and cautions. The text is unbiased; it does not contain information about the drug only from the drug company.

United States Pharmacopeia—Drug Information (USP-DI) is a three-volume set that is available in most hospitals and pharmacies and supplies monthly supplements. The first two volumes, Volumes IA and IB, provide drug information for the health care provider. They include pharmacology, precautions to consider, side effects and adverse effects, patient consultation, general dosing information, and dosage forms. Volume II offers drug information for the patient. It explains the information in a way the patient can understand. The topics include administration of drugs, drug effects, indications, adverse reactions, dosage guidelines, and what to do for missed doses.

The *Medical Letter* on drugs and therapeutics is a nonprofit publication for physicians, nurse practitioners, and other health professionals. Biweekly issues cover one of two themes, such as (1) drugs for the treatment of disease entities (e.g., human immunodeficiency virus, peptic ulcers) and (2) two to four new drugs that have been recently approved by the FDA. Information for each new drug includes pharmacokinetics, clinical studies, dosage, adverse effects, and interactions.

Prescriber's Letter is a newsletter published monthly by the Therapeutic Research Center in Stockton, California. It addresses new FDA-approved drugs, various uses of older drugs, and FDA warnings.

Handbook on Injectable Drugs by Lawrence A. Trissel is published by the American Society of Hospital Pharmacists. It is an excellent reference for injectable medications and lists drug compatibility with other drugs, base fluids, and drugs available in large-volume parenterals. Also, it includes the pH of each drug and offers some dosing administration guidelines.

MedlinePlus is a service of the U.S. National Library of Medicine. Available at *www.nlm.nih.gov/medlineplus/druginformation*, it offers extensive information on prescribed drugs as well as herbs and supplements, indexed by generic and brand names. Other key websites are listed at the end of each chapter of this text.

U.S. FOOD AND DRUG ADMINISTRATION PREGNANCY CATEGORIES

The FDA has developed a classification system related to the effects of drugs on the fetus. These categories are described in Chapter 12.

NCLEX STUDY QUESTIONS

1. The nurse is having a health teaching session with a patient who has many questions about the history of drug labels. What is the nurse's best legislation reference for drug labels and increased control on drug safety?
   a. Kefauver-Harris Amendment to the 1938 Act
   b. Controlled Substances Act
   c. Food, Drug, and Cosmetic Act
   d. Durham-Humphrey Amendment to the 1938 Act
2. The nurse is reviewing a patient's list of medications and notes that several have the highest abuse potential. According to U.S. standards, the highest potential for abuse of drugs with accepted medical use is found in drugs included in which schedule?
   a. II
   b. III
   c. IV
   d. V
3. The nurse is reviewing the drug-approval process in the United States and learns that the Food and Drug Administration Modernization Act of 1997 contains which provisions? (Select all that apply.)
   a. Review of new drugs is accelerated.
   b. Drug companies must provide information on "off-label" drugs.
   c. Privacy of individually identifiable health information must be protected.
   d. Drug companies must offer advanced notice of plans to discontinue drugs.
   e. Drug labels must describe side effects and adverse effects.

4. The patient has questions about counterfeit drugs. Which factors alert the patient or nurse that a drug is counterfeit or adulterated? (Select all that apply.)
   a. Variations in packaging
   b. Unexpected side effects
   c. Different taste
   d. Different chemical components
   e. Different odor
5. The nurse must be knowledgeable about the Nurse Practice Act. In the event the nurse gives the correct drug via the wrong route, resulting in the death of the patient, what may the nurse be charged with in a civil court?
   a. Misfeasance
   b. Nonfeasance
   c. Malfeasance
   d. Negligence
6. The nurse knows the importance of administering the right medication to the patient and that drugs have many names. It is therefore most important that drugs be ordered by which name?
   a. Generic
   b. Brand
   c. Trade
   d. Chemical
7. A drug label has "t/c" on it. The nurse knows that which statement is true about this designation? (Select all that apply.)
   a. It is on all schedule F prescription drugs.
   b. It is on targeted substances, such as benzodiazepines.
   c. It is a designation of the Canadian Controlled Drugs and Substances Act.
   d. It is on all narcotics.
   e. It is on over-the-counter drugs.
8. What provisions from the Controlled Substances Act of 1970 were designed to remedy drug abuse?
   a. The act established treatment and rehabilitation facilities.
   b. The act tightened controls on experimental drugs.
   c. The act required clinical trial data on drugs.
   d. The act required drug companies to give information on off-label drugs.

Answers: 1, a; 2, a; 3, a, b, d; 4, a, b, c; 5, c; 6, a; 7, b, c; 8, a.

OBJECTIVES

- Recognize verbal and nonverbal communication practices of various social and cultural groups.
- Explain appropriate spatial configurations for patients when delivering nursing care.
- Discuss the importance of including significant members of the social group in planning and implementation of patient care.
- Compare patients' perception of time based on cultural constructs.
- Describe patients' need to exercise control in their environment.
- Anticipate potential unique responses to drugs based on social, cultural, and biologic influences.
- Safeguard patients' rights to confidentiality during inclusion of significant others in the plan of care.

ETHNOPHARMACOLOGY

Ethnopharmacology is the study of drug responses that may be unique to an individual owing to social, cultural, and biologic phenomena. The emergence of ethnopharmacology highlights the need for nurses to use knowledge and research from the social sciences as well as the biologic and physical sciences to provide holistic nursing care.

Pharmacogenetics integrates the study of pharmacokinetics, pharmacodynamics, and variations of the predicted response to a drug due to genetic factors. The nurse must integrate knowledge of pharmacogenetics within patients' cultural contexts. **Culture** is defined as sets of learned behavior and ideas that human beings acquire as members of a community. A **community** is a cluster of individuals who function as a group to attain cultural universals. **Cultural universals** are designed to meet the community's survival needs and common goals such as the obtainment of food and other practices that maintain the group. Providing culturally competent care complements the Quality and Safety Education for Nurses (QSEN) initiative (see Chapters 11 and 12 for more information on QSEN).

TRANSCULTURAL NURSING

The concept of transcultural nursing was formalized by Madeleine Leininger, a nurse anthropologist. She founded the Transcultural Nursing Society in 1974. A challenge for nurses worldwide is the degree of cultural diversity owing to migration and global movement. Numerous cultural groups engage in the use of **traditional health practices**, which may include use of teas, herbs, spices, and special foods as well as homeopathic remedies, poultices, and ointments. These practices can have neutral, beneficial, or deleterious effects on a patient's health. The nurse must obtain a thorough health history to determine all the pharmacotherapeutic agents the patient is using. Obtaining a thorough history is more difficult than it seems; patients may not reveal all information, assuming that because herbs, teas, and spices are natural substances, they are therefore not drugs. They may also be reluctant to share this information with a conventional health care practitioner.

Healers play a role in traditional health practices in about 80% of the population worldwide. Traditional healers usually have some practical knowledge of human anatomy and physiology, pharmacology, and pharmaceutical substances. Healers may combine practical knowledge with rituals that seek to control otherworldly forces such as deities or spirits. Every cultural group has its own traditions, superstitions, and belief systems. Throughout history, healing practices, religious ideology, and spirituality have been tightly intertwined.

Owing to varying degrees of assimilation and acculturation within and among cultural groups, it is essential for the nurse to not make generalizations about an individual's beliefs or behaviors. **Assimilation** occurs when a less powerful group changes its ways to blend in with the dominant cultural group. Adults who immigrate to a new region usually take longer to assimilate than do younger people. **Acculturation** is the process by which a group adjusts to living within a dominant culture while at the same time maintaining its original identity. This sets the stage for **complementary health practices** that combine traditional beliefs and mainstream health practices.

Adding to the challenges faced by nurses in countries with numerous cultural groups is the phenomenon of the dominant group borrowing traditional health practices from other groups. When a dominant group adopts health practices from a nondominant group, they are called **alternative health practices.**

Use of complementary and alternative health practices is growing in the United States. A major impetus for this movement is that many individuals experience difficulty accessing or paying for mainstream health care. Even individuals who have access to mainstream health care may perceive that it is not personalized or effective, so they may opt for complementary health care (using a new therapy along with a mainstream therapy already in use) or alternative health care (using a new therapy in place of a mainstream therapy). This is evidenced by the vast amounts of teas and herbs available in most supermarkets (see Chapter 6) and by the increase in the use of acupuncture, acupressure, and massage as therapies.

HERBAL ALERT 3-1

Gender-Specific Herb Protocols

Women have traditionally sought substitutes for hormonal replacement therapy. More women are now using phytoestrogens like those found in flaxseed, licorice, black cohosh, and soybeans. Health care providers should ask patients about the use of these naturally occurring phytoestrogens because they are contraindicated in women with a history of or risk for hormonally mediated cancers and benign tumors.

THE GIGER AND DAVIDHIZAR TRANSCULTURAL ASSESSMENT MODEL

The Transcultural Assessment Model, developed by Giger and Davidhizar in 1998, suggests that all cultures have six cultural phenomena. These cultural phenomena flow from a culturally unique individual (Figure 3-1). The model has been frequently reviewed for relevancy and has been clinically useful for nurses and other members of the health care team.

Communication

Communication occurs verbally and nonverbally. Nurses must be alert to different types of communication styles among patients to provide culturally competent care.

Language

Patients' use of languages other than English may pose a challenge to nurses working in the United States. Professional translators should be used whenever possible to safeguard a patient's confidentiality. If a professional translator is not available, the nurse must select an alternative person carefully. (For example, asking the teenage son of a patient with gynecological health issues to translate may create an uncomfortable situation that is better avoided.) Even with the use of a translator, nuances in languages are unique and may not lend themselves to accurate translation in another language. There can be miscommunication between the patient, the translator, and the nurse.

Nurses should not confuse politeness with meaningful communication. Many patients will nod in agreement to

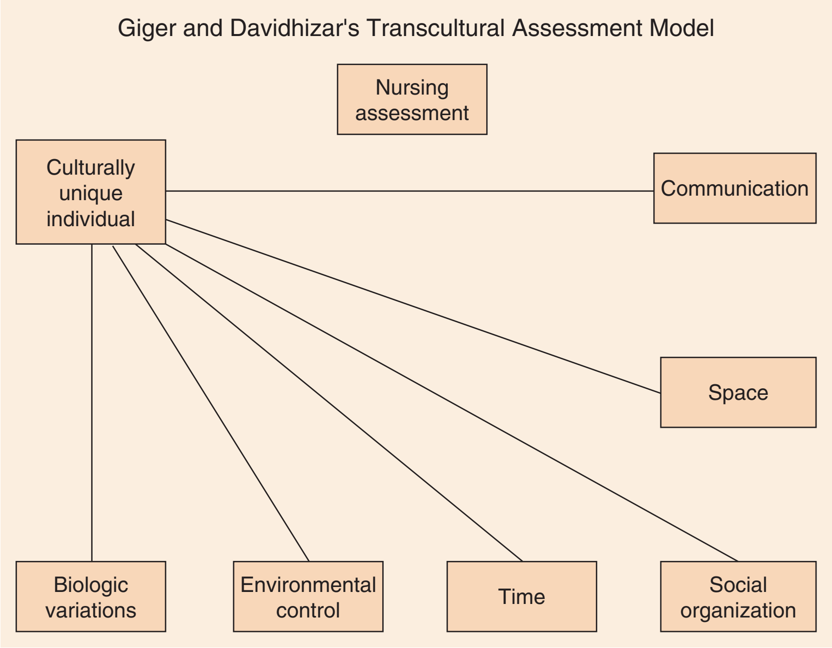

FIGURE 3–1 The Giger and Davidhizar Transcultural Assessment Model. (From Giger J, Davidhizar R: *Transcultural nursing: assessment and intervention,* ed. 6, St Louis, 2013, Elsevier.)

statements made by the nurse even if the statements are not well understood because of language differences.

Vernacular English

Adding to the challenge of communication is the pervasive use of words and phrases that are popular in particular social or cultural groups. For example, the term "African-American Vernacular English" has been used to describe a style of English speaking that is used among some African Americans. It is thought to have its roots in the myriad of West African languages spoken by slaves brought to America. More generally, vernacular English is any style of English that varies from standard English. Its use by patients can lead to misunderstanding by the nurse or to other communication difficulties.

Greetings and Communication Styles

All cultures have prescribed norms for greeting and addressing others. Americans of European descent may be more informal when greeting and addressing others than descendants of non-European cultures. Nurses must keep in mind that patient-nurse interactions in health care settings are considered formal and that informal styles of communication should be used only after careful consideration.

For example, a communication style that might hinder culturally competent nursing care may be found in some patients of Asian descent, who might speak in a soft tone of voice and avoid direct eye contact. The nurse who is unaware of this may miss cues that care is needed. Asian Americans and Native Americans may be comfortable with periods of silence, while persons of Latin American, African, or European descent may be uneasy during periods of silence. Being cognizant of these preferences will help the nurse provide a comfortable environment for the patient.

Space

The amount of space around a person's body is an important psychological consideration. Americans may desire a great deal of personal space. In some other cultures, population density may dictate limited personal space. Patients who are used to dense living quarters may feel insecure in a hospital room. It is important that the nurse have frequent contact with these patients and allow significant members of the social group to remain with the patient as much as possible.

A major challenge in caring for patients is the use of touch and the protection of modesty. Although nurses must touch patients to administer care, all cultures have taboos regarding touch. There are added considerations when the patient is of a different gender than the nurse. This is a particularly sensitive issue for groups within the Muslim, Orthodox Jewish, Amish, and Roma communities. For example, a Muslim woman may prefer to be cared for by a female nurse rather than a male nurse. Nurses should consider inquiring about patients' preferences regarding touch before implementing nursing care. It may be best to have a family member of the same gender as the patient present during procedures, if possible. There may also be apparent paradoxes within cultures; for example, persons of Hispanic descent may value human contact but also value modesty.

Social Organization

Families are basic social units. The definition of family and the criteria for inclusion varies among individuals and among cultures. Americans of western European descent may have small, nuclear families, whereas other cultural groups living in the United States may have larger, extended families. Delivery of nursing care can be enhanced by including family whenever appropriate; nurses are in a position to advocate for inclusion of family in health care settings. Limiting the amount of time a patient can visit with members of the social group is a long-standing practice in American health care settings, but in some other countries, such as the Philippines, it is expected that family members will stay by the patient's bedside and participate in his or her care.

Time

Nurses and their patients may have different perceptions of time. Time moves slowly for a patient who is anxious or in pain but moves quickly for a nurse who has a demanding workload. The use of vague terms to denote time may also cause a disparity between nurses' and patients' perceptions of time. Words like *now, soon,* or *later* may have vastly different nuances among individuals and groups.

Adding to the complexity of time perception are the concepts of *linear* time and *circular* time. When time is perceived as linear, the present flows into the future and is irretrievably lost. Viewing time as linear is likely to prompt thinking such as "I must do this now." When time is perceived as circular, the present has more stability and the need to do things at the moment has less urgency. Viewing time as circular is likely to prompt thinking such as, "I will have the opportunity to do this later."

The cultural aspect of time perception has a profound effect on pharmacotherapeutic adherence. All cultures have a concept of time as it is related to the past, present, and future. All humans are acutely aware that the present is here and now and in real time; it is the *relative importance* placed on the past, present, and future that directs the use of time.

People of western European descent may exhibit a great deal of future orientation. This can lead to health practices perceived to prevent illness, such as adhering to a low-fat diet to prevent higher cholesterol or wearing a condom during sex to prevent disease. Concern for the future also serves as motivation to take steps to control chronic illness, which is likely to lead to greater adherence to long-term pharmacotherapy. Explanations for these phenomena are that people of western European descent have historically experienced longevity and expect to have a lengthy future, and that their economic and social lives have revolved around calendars and clocks for centuries.

Non-European cultural groups such as those of African, Asian, Native American, or Latin American descent have exhibited less dependence on strict time schedules for economic and social activities. These groups' perception of time may be rooted in agrarian cultures that use daily and seasonal rhythms of the earth and the sun to direct activities. This could result in emphasis being placed on the present; measures to ease the discomfort of a current illness may take precedence over measures to promote long-term wellness or treat a chronic illness. Patients with a present-oriented perception of time are more likely to discontinue mainstream prescriptive therapies when they feel well. It must be noted, however, that with the shrinking of agrarian cultures and the spreading of European-style practices, this treatment of time is changing. The nurse must therefore assess the patient's degree of acculturation or assimilation.

Cultural groups that are steeped in traditional practices or perceive that their cultural identities are threatened are likely to have a past orientation of time, which may lead to the use of traditional health practices over mainstream health practices. Health behaviors of individuals are also influenced by the quantity and quality of past experiences with the health care system.

Environmental Control

A major aspect of culture is the desire to control nature to facilitate the needs of human beings. The concept of "nature" may include otherworldly forces or beings, such as deities and spirits. Illness may be attributed to cosmic forces and believed to be cured or ameliorated by persons who possess special abilities. Traditional healers are thought to have influence over otherworldly forces.

Healers and spiritual advisors can be beneficial in health care settings; examples include the practice of clergy (e.g., minister, priest, rabbi) visiting ill members of a congregation or the inclusion of a traditional healer in the plan of care.

The Indian Health Service is a federal agency within the U.S. Department of Health and Human Services that oversees the health care of approximately 2 million Native Americans who belong to federally recognized tribes. Similarly, the Canadian health care system has developed many initiatives to improve the health care of its indigenous peoples, known as *First Nation*, *Inuit*, and *Metis*. In both systems, the use of traditional healers and spiritual guides is incorporated into mainstream prescriptive therapies.

Biologic Variations

Through the work of the *Human Genome Project,* an international collaborative research program, the field of pharmacogenomics is rapidly expanding. In the United States, the project is managed by the National Human Genome Research Institute, which is part of the National Institutes of Health (NIH). **Pharmacogenomics** refers to the general study of all the different genes that determine drug behavior. An example of a significant finding of pharmacogenomics is the effect of the Cytochrome P-450 (CYP) enzymes on drug response, drug-drug interactions, and adverse drug events, which are described later in the chapter.

The Genographic Project has performed DNA testing on populations all over the world. Findings reveal that human beings are 99.9% genetically identical; this implies that there are not multiple races but multiple genotypes (an individual's genetic identity).

To illustrate the significance of these findings to the patient care setting, it is necessary to review additional terms used in the fields of pharmacogenomics and pharmacogenetics. **Genomes** are a complete set of chromosomes and make up a cell's DNA. **Polymorphisms** are DNA variants that occur within a specific population at a frequency greater than 1%. A **substrate** is a substance that binds to and is metabolized by one or more enzymes. Drugs are chemical substances and a type of substrate. The Cytochrome P-450 enzyme system either induces or inhibits the action of substrates. Induction or inhibition of a substrate accounts for the variations in drug metabolism in individuals and groups. The Division of Clinical Pharmacology at Indiana University Department of Medicine continually updates a clinically relevant table of drug interactions caused by the Cytochrome P-450 system.

Human migration around the world has been so vast over such a long period that most people have a variety of genetic markers. The study of pharmacogenetics can pave the way for pharmacotherapy that yields greater therapeutic benefits and causes fewer adverse reactions. The application of pharmacogenetics should be approached with caution. A person who is dark-skinned and appears to be of African descent is likely to have some European genetic markers.

Certain classifications of medications have different effects in individuals whose genetic markers are predominantly characteristic of a certain biologic group. For example, in the United States, Caucasian people are more likely than people of Asian or African heritage to have abnormally low levels of the CYP2D6 enzyme that metabolizes drugs belonging to a variety of therapeutic areas, such as antidepressants, antipsychotics, and beta blockers.

African Americans respond poorly to several classes of antihypertensive agents (beta blockers and angiotensin-converting enzyme inhibitors). Differences in skin structure and physiology can affect response to dermatologic and topically applied products. Clinical trials have demonstrated lower responses to interferon-alpha used in the treatment of hepatitis C among African Americans compared with other racial subgroups.

As another example, the U.S. Food and Drug Administration has entered into an agreement with the manufacturers of drugs containing carbamazepine (Tegretol) to include product labeling recommending that patients of Asian ancestry be genetically tested before starting on this agent. There is a strong association between serious skin reactions and an inherited variant of the *H 1502LA-B* gene found in Asians.

These intrinsic biologic factors must be considered along with extrinsic factors such as diet and environmental and sociocultural issues to prescribe effective therapies and provide holistic health care.

Researchers conducting clinical trials for development of new drugs are now required to obtain genetic testing of the participants in the study. Issues to be resolved before widespread testing are the cost-versus-benefit ratio and ethical considerations. Genetic testing is expensive and generally not covered by third-party payers. Genetic information can affect employment, insurability, and family relationships.

Table 3-1 applies the Giger and Davidhizar Transcultural Assessment model to four broad cultural categories of peoples of European descent, African descent, Latin and Native American descent, and Asian descent. It is important to keep in mind that there is no generic prototype for any of these categories. Italian Americans are likely to have different customs than German Americans. There may be a perception in the United States that most Asians are Chinese and most Hispanics are Mexican, but in fact there is great variation among these broad groups regarding geography of origin, language, customs, and spiritual systems. Another misperception in the United States is that people of African descent are from one country, but Africa comprises 54 countries over a large geographical area; language, customs, and spiritual systems vary extensively.

Box 11-1 in Chapter 11 supplies additional information on culturally sensitive care.

Nursing Process
Patient-Centered Collaborative Care

Cultural and Pharmacogenetic Considerations

Assessment

- Assess patient's ability to communicate using standard English.
- Determine if patient participates in traditional health practices and/or complementary or alternative medical practices.
- List patient's use of pharmacotherapeutic agents, including prescription medications, over-the-counter medications, herbs, and teas.
- Ascertain if including a traditional healer would facilitate compliance with prescriptive therapies.
- Inquire about patient's preferences regarding touch, modesty, and personal space.
- Gauge patient's perception of time.

Nursing Diagnoses

- Anxiety related to inability to communicate and understand diagnosis
- Impaired verbal communication related to not understanding primary language
- Ineffective community coping related to lack of relationships with members of the community
- Ineffective self–health management related to not accessing or understanding health care resources

Planning

- Patient's health care needs will be met within a culturally competent framework.
- Patient will effectively manage health care.

Nursing Interventions

- Use appropriate persons as translators when patient's use of standard English is limited.
- Anticipate that therapeutic communication with patient and significant others who use limited standard English will require additional time with each encounter.

TABLE 3-1 SELECTED ETHNIC/CULTURAL GROUPS AND COMPONENTS OF THE GIGER AND DAVIDHIZAR TRANSCULTURAL ASSESSMENT MODEL*

CULTURAL PHENOMENA	COMMUNICATION STYLES	SPATIAL PREFERENCES	SOCIAL ORGANIZATION	PERCEPTION OF TIME	ENVIRONMENTAL CONTROL	BIOLOGIC VARIATIONS
People of European descent	Prefer direct eye contact. Use moderate to loud vocal volume. Use many words to describe symptoms. Uncomfortable with periods of silence.	Prefer a large amount of personal space. Value privacy. Exhibit a low to moderate amount of touching among group members.	Small, nuclear families. Extended family members often live a far distance away. High degree of individualism.	High level of importance placed on the future. Expect that the present level of comfort be addressed. Little focus on the past.	Primarily believe that healthy behaviors prevent illness. Secondarily believe that illness is caused by cosmic forces. Believe in being united with a deity in the afterlife.	Poor metabolizers of antidepressants, antipsychotics, cardiovascular agents, and isoniazid (INH), which can lead to toxicity.
People of African descent	Prefer direct eye contact. Use moderate to loud vocal volume. Uncomfortable with periods of silence.	Comfortable with a smaller amount of personal space. Exhibit moderate amount of touching among group members.	Small, nuclear families in America but might classify nonrelated persons as family. Important to recognize these members of the social group.	High level of importance placed on the present. Connected with the past as evidenced by the use of home remedies passed through generations. Become more concerned with the future as longevity increases.	Spiritually oriented. Important to include clergy in care. Believe in being united with a deity in the afterlife.	May have diminished therapeutic effects from beta blockers, ACE inhibitors, and warfarin sodium (Coumadin).
People of Latin American descent and Native Americans	Not likely to make direct eye contact with persons perceived to be in authoritative positions. Varying degrees of comfort with silence.	Comfortable with a small amount of personal space. Latin Americans value touching. Native Americans use touch lightly.	Large, extended families. Important to include family members in care.	High level of importance placed on the present. Connected with the past as evidenced by the use of traditional healers. Become more concerned with the future as longevity increases.	Spiritually oriented. Followers of Christian religions derive comfort from religious artifacts such as rosary beads. There may be multiple deities in indigenous religions.	Native Americans have a high incidence of lactose intolerance resulting in low-calcium diets. Also exhibit enhanced vasomotor responses to alcohol.

*This table is limited in scope and does not necessarily reflect an individual's beliefs, behaviors, or biologic functioning.

- Provide appropriate spatial configurations for individual patients and members of their social groups when delivering nursing care.
- Include significant members of the social group in planning and implementation of patient care.
- Allow patient adequate time with significant members of the social group.
- Recognize the need for patients to exercise control in their environment.
- Anticipate unique responses to drugs based on social, cultural, and biologic influences.
- Consult with persons who are knowledgeable about the patient's culture and mainstream culture.
- Incorporate nonharmful traditional health practices with mainstream prescriptive therapies when appropriate.
- Facilitate adherence to mainstream prescriptive therapies within patient's social and cultural contexts.

Patient Teaching

- Include significant members of the social group, when appropriate, while teaching about prescriptive therapies.
- Provide health information written in the patient's primary language. Medline, an online service of the National Institutes of Health, offers a variety of patient education materials in a number of languages available at *www.nlm.nih.gov/medlineplus/languages/languages.html*.
- Use illustrations to explain prescriptive therapies.

Evaluation

- Monitor for patient adherence to prescriptive therapies.
- Evaluate physical, social, and psychological outcomes of prescriptive therapies.

CRITICAL THINKING CASE STUDY

1. NS is a 72-year-old woman who immigrated to the United States from Egypt 5 years ago. She is a widow, has five grown children, and follows Islamic doctrine. She lives with her oldest daughter. A younger daughter and three sons live near her home. NS is currently hospitalized owing to a recent cerebral vascular accident. She has left-sided paralysis. The attending physician tells the patient she should go to a rehabilitation unit for 3 weeks for physical therapy. The oldest daughter is present for the physician's visit. Both the patient and her daughter appear anxious but do not ask the physician any questions.
    1. What cultural factors could explain the apparent anxiety?
    2. Which nursing interventions would help decrease the anxiety?
    3. How may the patient view the idea of physical therapy?
    4. What should the nurse consider before applying an ointment?

NCLEX STUDY QUESTIONS

1. The nurse is performing a health assessment on a newly admitted patient of Asian descent. The patient looks at the floor whenever the nurse asks a question. Communication is enhanced when the nurse does which action?
    a. Frequently touches the patient
    b. Asks questions that require only "yes" or "no" for answers
    c. Discontinues the health assessment
    d. Uses eye contact sparingly
2. The nurse has been measuring the blood pressure of an African-American patient every 4 hours for the past 3 days in a hospital setting. The blood pressure is consistently above 140/90. The patient has been compliant with the antihypertensive drug therapy while hospitalized. The nurse will initially perform which action?
    a. Question the patient about the types of food consumed in the last 3 to 4 days.
    b. Inform the prescriber that the antihypertensive drug therapy is not working.
    c. Increase blood pressure measurements to every 2 hours.
    d. Place the patient on a restricted fluid intake.
3. A nurse who is male is caring for a young, married woman who is an observant Muslim. It is important that the nurse perform which action?
    a. Touch no part of the patient's body.
    b. Identify the patient's preference regarding touch.
    c. Touch the patient only when her spouse is present.
    d. Tell the nurse manager he cannot care for female patients who practice Islam.

4. A nurse is teaching a 16-year-old female patient about a newly prescribed medication. The patient is bilingual in Spanish and English. Which behavior best indicates the patient's understanding of the instructions?
   - **a.** The patient frequently nods her head while listening to the nurse's instructions.
   - **b.** The patient states that she understands the instructions.
   - **c.** The patient repeats the nurse's instructions to her parents.
   - **d.** The patient does not ask the nurse for clarification of the instructions.
5. A Native American patient is newly diagnosed with diabetes mellitus type 2 and is prescribed the antidiabetic drug metformin (Glucophage) 500 mg PO with morning and evening meals. Which statement best indicates to the nurse that the patient will adhere to the pharmacotherapy?
   - **a.** "I will no longer put sugar on my cereal because that will help me be healthier."
   - **b.** "If I take this medicine, I will feel better soon and won't have to take it anymore."
   - **c.** "To reduce the possibility of damage to my body, I must take the medicine as scheduled."
   - **d.** "I have diabetes because of my ancestry, so there's not much I can do about it."

Answers: 1, d; 2, b; 3, b; 4, c; 5, c.

CHAPTER 4

Drug Interactions and Over-the-Counter Drugs

evolve WEBSITE

- Key Points
- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Differentiate the four pharmacokinetic processes related to drug interaction.
- Explain the three effects associated with pharmacodynamic interactions.
- Discuss drug interaction, and give examples
- Describe the effects of drug-food interactions.
- Explain the meaning of drug-induced photosensitivity.
- Discuss the nursing implications related to patients' use of over-the-counter drugs.

over-the-counter drugs, p. 29
photosensitivity, p. 34
synergistic effects, p. 33

Drug therapy is complex because of the great number of drugs available. Drug-drug, drug-food, and drug-laboratory interactions are an increasing problem. Because of the possibility of numerous interactions, the nurse should be knowledgeable about drug interactions and should closely monitor patient responses. Thorough and timely communication among members of the health team is essential. Patients at high risk for interactions include those who have chronic health conditions, take multiple medications, see more than one health care provider, and use multiple pharmacies. Older adults are at especially high risk for drug interactions; 75% take prescription drugs, and 82% take **over-the-counter (OTC) drugs**—drugs that are obtainable without a prescription.

DRUG INTERACTIONS

A **drug interaction** is defined as an altered or modified action or effect of a drug as a result of interaction with one or multiple drugs. It should not be confused with adverse drug reaction or drug incompatibility. An **adverse drug reaction** is an undesirable drug effect that ranges from mild untoward effects to severe toxic effects, including hypersensitivity reaction and anaphylaxis. **Drug incompatibility** is a chemical or physical reaction that occurs among two or more drugs in vitro. In other words, the reaction occurs between two or more drugs within a syringe, IV bag, or other artificial environment outside of the body.

Drug interactions can be divided into two categories: (1) pharmacokinetic interactions and (2) pharmacodynamic interactions.

Pharmacokinetic Interactions

Pharmacokinetic interactions are changes that occur in the absorption, distribution, metabolism or biotransformation, and excretion of one or more drugs.

Absorption

When a person takes two drugs at the same time, the rate of absorption of one or both drugs can change. One drug can block, decrease, or increase the absorption of another drug. It can do this in one of the following ways:

1. By decreasing or increasing gastric emptying time
2. By changing the gastric pH
3. By forming drug complexes

Drugs that increase the speed of gastric emptying (e.g., laxatives, metoclopramide [Reglan]) may cause an increase in gastric and intestinal motility and a decrease in drug absorption. Most drugs are absorbed primarily in the small intestine; exceptions include barbiturates, salicylates, and theophylline (Theo-24), which undergo gastric absorption. Opioids and anticholinergic drugs (e.g., atropine) decrease gastric emptying time and gastrointestinal (GI) motility, causing an increase in absorption rate. For drugs that undergo gastric absorption, the amount or extent of absorption increases the longer the drug remains in the stomach.

When the gastric pH is decreased, a weakly acidic drug like aspirin is less ionized and more rapidly absorbed. Drugs that increase the gastric pH decrease absorption of weak-acid drugs. Antacids such as magnesium hydroxide (Maalox) and aluminum hydroxide (Amphojel) raise the gastric pH and block or slow absorption. Some drugs may react chemically. For example, tetracycline and the heavy-metal ions (calcium, magnesium, aluminum, and iron) found in antacids or iron supplements may lead to the formation of a drug complex and thus prevent the absorption of tetracycline. This phenomenon may also be observed when products that contain divalent cations are ingested with fluoroquinolone antibiotics such as ciprofloxacin (Cipro). Consequently, dairy products, multivitamins, and antacids should be avoided 1 hour before and 2 hours after tetracycline or ciprofloxacin consumption.

Certain cholesterol-lowering drugs, such as cholestyramine and colestipol, also form complexes with drugs like carbamazepine (Tegretol) and furosemide (Lasix). The drugs are then less soluble, resulting in reduced drug absorption. Drug complexation may be desired; for example, activated charcoal may be administered after toxic ingestion of a medication to decrease its absorption and, consequently, diminish or eliminate any untoward effects associated with the overdose.

Alteration of bacteria normally found in the GI tract may affect the pharmacokinetics of a medication. For example, intestinal microflora have the ability to metabolize digoxin (Lanoxin). Digoxin is a digitalis preparation that is used to treat heart failure and arrhythmias. Metabolism of this drug by gut bacteria decreases its bioavailability. Erythromycin, a macrolide antibiotic, and tetracycline are broad-spectrum antibiotics (effective against both gram-positive and gram-negative organisms) that destroy or inhibit the growth of these GI microflora. Consequently, the administration of one of these drugs to a patient on digoxin therapy may lead to an increase in the absorption of digoxin and, ultimately, to toxicity. Another example of this phenomenon occurs with oral contraceptives. Gut bacteria are necessary to hydrolyze estrogen conjugates into free estrogens so they may be optimally absorbed to exert their contraceptive effect. Concurrent antibiotic administration may alter these intestinal bacteria, impairing this process and preventing the optimal absorption and effectiveness of the oral contraceptive. A patient who takes oral birth control to prevent pregnancy should use a barrier form of protection during sex when she takes a course of antibiotics.

Distribution

A drug's distribution to tissues can be affected by its binding to plasma/serum protein. Only drugs unbound to protein are free active agents and can enter body tissues. Two drugs that are highly protein bound and administered simultaneously can result in drug displacements. Factors that influence displacement of drugs are (1) drug concentration in the blood, (2) protein-binding power of the drugs, and (3) volume of distribution (Vd).

Two drugs that are highly bound to protein or albumin will compete for binding sites in the plasma. The result is a decrease in protein binding of one or both drugs; therefore, more free drug circulates in the plasma and is available for drug action. This effect can lead to drug toxicity. When two highly protein-bound drugs must be taken concurrently, the drug dosage of one or both drugs may need to be decreased to avoid drug toxicity.

Drugs that are highly protein bound include the anticoagulant warfarin, anticonvulsants such as phenytoin and valproic acid, gemfibrozil (antihyperlipidemic), most nonsteroidal antiinflammatory drugs (NSAIDs), sulfisoxazole (sulfonamide), glyburide (antidiabetic), and quinidine (antidysrhythmic). Warfarin (Coumadin) is 99% protein-bound, allowing only 1% to be free drug. If 2% to 3% of warfarin is displaced from albumin binding sites, the amount of free warfarin would be 3% to 4% instead of 1%. This action has the potential to increase the anticoagulant effect of warfarin; excess bleeding may result.

A significant decrease in serum albumin level because of liver disease or poor nutritional status can increase the free amount of highly protein-bound drugs such as phenytoin and warfarin, making more drug available to exert its pharmacologic effect.

Metabolism or Biotransformation

Many drug interactions of metabolism occur with the induction or inhibition of the hepatic microsomal system. A drug can increase the metabolism of another drug by stimulating liver enzymes. These enzymes produce a cascade effect in drug function. Drugs that promote induction of enzymes are called *enzyme inducers.* Barbiturates like phenobarbital are enzyme inducers. Phenobarbital increases the metabolism of most antipsychotics and methylxanthine (theophylline). Increased metabolism promotes drug elimination and decreases plasma concentration of the drug. The result is a decrease in drug action. Sometimes liver enzymes convert drugs to active or passive metabolites. The drug metabolites may be excreted or may produce an active pharmacologic response.

The anticonvulsant drugs phenytoin and carbamazepine and the antimicrobial medication rifampin are hepatic enzyme inducers that can increase drug metabolism—for example, for the anticoagulant drug warfarin. A larger dose of warfarin is usually needed while the patient takes a hepatic inducer, because metabolism aids in decreasing the amount of drug. If the drug inducer is withdrawn, warfarin dosages must be decreased, because less drug is eliminated by hepatic metabolism. Usually interaction occurs after 1 week of drug therapy and can continue for 1 week after the drug inducer is discontinued. Drugs with narrow therapeutic ranges should be closely monitored.

Some drugs are enzyme inhibitors. The antiulcer drug cimetidine (Tagamet) is an enzyme inhibitor that decreases metabolism of certain drugs such as theophylline, causing an increase in the plasma concentration of theophylline. The theophylline dose must be decreased to avoid toxicity. If cimetidine or any enzyme drug inhibitor is discontinued, the theophylline dosage should be adjusted. Other well-known hepatic enzyme inhibitors are erythromycin (an antibacterial) and itraconazole (an antifungal).

The use of tobacco and alcohol may have variable effects on drug biotransformation. Polycyclic aromatic hydrocarbons found in cigarette smoke induce production of the specific family of enzymes responsible for theophylline metabolism. Chronic cigarette smoking leads to an increase in hepatic enzyme activity and can increase theophylline clearance. Asthmatics who smoke and take theophylline to manage their disease may require an increase in theophylline dosage. The ingestion of alcohol may have variable effects on biotransformation. With chronic alcohol use, hepatic enzyme activities are increased; with acute alcohol use, metabolism is inhibited.

Natural or herbal products may also have an impact on metabolism. St. John's wort, an OTC herbal product used to manage symptoms of depression, induces the metabolism of certain drugs such as warfarin, digoxin, and theophylline. This action potentially decreases the effectiveness of these medications, possibly necessitating a dose increase to sustain efficacy. Flavonoids, a group of naturally occurring compounds found in the juice and pulp of citrus fruits, are potent inhibitors of the metabolism of certain drugs. Patients who are stabilized on therapeutic doses of carbamazepine, diazepam, statins, calcium channel blockers, or erectile dysfunction drugs may subject themselves to adverse effects from greater-than-expected drug levels if they eat or drink grapefruit products concurrently with the drug.

Certain drugs alter hepatic blood flow, causing a decrease in liver metabolism. Table 4-1 describes the effects of drug enzyme inducers and inhibitors.

TABLE 4-1 **DRUGS: ENZYME INDUCERS AND ENZYME INHIBITORS**

DRUG CATEGORY	DRUG EFFECT
Drug enzyme inducer	Onset and termination of drug effect is slow, approximately 1 week. Drug dosage may need to be increased with use of drug inducer. Drug dosage should be adjusted after termination of drug inducer. Monitor serum drug levels, especially if the drug has a narrow therapeutic drug range.
Drug enzyme inhibitor	Onset of drug effect usually occurs rapidly. Half-life ($t\frac{1}{2}$) of the second drug may be increased, causing a prolonged drug effect. Interaction may occur related to the dosage prescribed. Disease entities affect drug dosing. Monitor serum drug levels, especially if the drug has a narrow therapeutic range.

Excretion

Most drugs are filtered through the glomeruli and excreted in the urine. With some drugs, excretion occurs in the bile, which passes into the intestinal tract. Drugs can increase or decrease renal excretion and have an effect on the excretion of other drugs. Drugs that decrease cardiac output, decrease blood flow to the kidneys, and decrease glomerular filtration rate can also decrease or delay drug excretion. The antiarrhythmic drug quinidine decreases the excretion of digoxin; therefore, the plasma concentration of digoxin is increased, and digitalis toxicity can occur.

Diuretics promote water and sodium excretion from the renal tubules. Furosemide (Lasix) acts on the loop of Henle, and hydrochlorothiazide (HydroDIURIL) acts on the distal tubules. Both diuretics decrease reabsorption of water, sodium, and potassium. A renal loss of potassium, which may lead to a condition known as *hypokalemia*, can enhance the action of digoxin, and digitalis toxicity could occur (see "Drug-Laboratory Interactions" later in the chapter).

Two or more drugs that undergo the same route of excretion may compete with one another for elimination from the body. Probenecid, a drug for gout, decreases penicillin excretion by inhibiting the secretion of penicillin in the renal tubules of the kidneys. In some cases, this effect may be desirable to increase or maintain the plasma concentration of penicillin (which has a short half-life) for a prolonged period of time.

Changing urine pH affects drug excretion. The antacid sodium bicarbonate causes the urine to be alkaline. Alkaline urine promotes the excretion of drugs that are weak acids (e.g., aspirin, barbiturates). Alkaline urine also promotes reabsorption of weak base drugs. Acid urine promotes the excretion of weak base drugs such as quinidine.

With decreased renal or hepatic function, there is usually an increase in free drug concentration. It is essential to closely monitor these patients for drug toxicity when they take multiple drugs. Checking serum drug levels, a practice also known as *therapeutic drug monitoring (TDM)*, is especially important for drugs that have a narrow therapeutic range and are highly protein bound. Digoxin and phenytoin are two drugs that require TDM. Table 4-2 summarizes the drug interactions that affect pharmacokinetics.

Pharmacodynamic Interactions

Pharmacodynamic interactions are those that result in additive, synergistic, or antagonistic drug effects.

Additive Drug Effect

When two drugs with similar action are administered, the drug interaction is called an **additive effect** and is the sum of the effects of the two drugs. Additive effects can be desirable or undesirable. For example, a desirable additive drug effect occurs when a diuretic and a beta blocker are administered for the treatment of hypertension. In combination, these two drugs use different mechanisms to have a more pronounced blood pressure–lowering effect. As another example, aspirin and codeine are two analgesics that work by different mechanisms but can be given together for increased pain relief.

An example of an undesirable additive effect is that from two vasodilators: hydralazine (Apresoline) prescribed for hypertension and nitroglycerin prescribed for angina. The result could be a severe hypotensive response. Another example is the interaction of aspirin and alcohol. Aspirin is directly irritating to the stomach, causes platelet dysfunction, and inhibits prostaglandin-mediated mucus production of

TABLE 4-2 **PHARMACOKINETIC INTERACTIONS OF DRUGS**

PROCESS	DRUG	EFFECT
Absorption	Laxatives	Speeds gastric emptying time Increases gastric motility Decreases drug absorption
	Opioids Anticholinergics	Slows gastric emptying time Decreases gastric motility Increases or decreases drug absorption, depending on where the drug is delayed (gastric vs. intestinal)
	Aspirin	Decreases gastric pH Increases drug absorption
	Antacids	Increases gastric pH Slows absorption of acid drugs
	Antacids and tetracycline	Forms drug complexes Blocks drug absorption
Distribution	Anticoagulant and antiinflammatory (sulindac)	Competes for protein-binding sites Increases free drug (e.g., increases anticoagulant)
Metabolism or biotransformation	Barbiturates	Promotes induction of liver enzymes Increases drug metabolism Decreases plasma concentration of second drug
	Antiulcer cimetidine (Tagamet)	Inhibits liver enzyme release Decreases metabolism of diazepam (Valium), phenytoin (Dilantin), morphine, and so on Increases plasma concentration of second drug
Excretion	Antiarrhythmic (quinidine)	Decreases renal excretion of second drug (e.g., digoxin) Increases digoxin concentration
	Antigout (probenecid)	Decreases penicillin excretion by competing for renal tubular secretion Increases penicillin concentration
	Antacid (sodium bicarbonate)	Promotes excretion of weak acid drugs (e.g., aspirin, barbiturates, sulfonamides)
	Aspirin, ammonium chloride	Promotes excretion of weak base drugs (e.g., quinidine, theophylline)
Other: Decrease in cardiac output and renal blood flow	Most drug categories	Decreases drug excretion Increases drug plasma concentration

the gastric mucosa, which protects the underlying tissues of the stomach. Alcohol disrupts the gastric mucosal barrier and suppresses platelet production. Both aspirin and alcohol can prolong bleeding time and, when taken together, may result in gastric bleeding.

Synergistic Drug Effect or Potentiation

When two or more drugs are given together, one drug can potentiate or have a **synergistic effect** on another. In other words, the clinical effect is substantially greater than the combined effect of the two. An example of this is the combination of meperidine (Demerol, synthetic opioid analgesic) and promethazine (Phenergan, antihistamine). One of the major side effects of promethazine is sedation. When used with meperidine in postsurgery patients, promethazine enhances or potentiates the drowsiness effect of meperidine. Less meperidine is required when it is combined with promethazine, which can be desirable. An example of an undesirable effect occurs when alcohol and a sedative-hypnotic drug, such as chlordiazepoxide (Librium) or diazepam (Valium), are combined. The resultant effect of this example is increased central nervous system (CNS) depression.

Some antibacterials (antibiotics) have an enzyme inhibitor added to the drug to potentiate the therapeutic effect. Examples are ampicillin with sulbactam (Unasyn) and amoxicillin with clavulanate (Augmentin), in which sulbactam and clavulanate potassium are bacterial enzyme inhibitors. Ampicillin and amoxicillin can be given without these inhibitors; however, the desired therapeutic effect may not occur because of the bacterial beta-lactamase, which inactivates the drugs and causes bacterial resistance. The combination of the antibiotic with either sulbactam or clavulanate inhibits bacterial enzyme activity and enhances the effect or broadens the spectrum of activity of the antibacterial agent. Not all bacteria secrete beta-lactamase enzyme; only those that do will inhibit these antibiotics and result in bacterial resistance. (Refer to Unit IX for information on antibacterial agents.)

Antagonistic Drug Effect

When two drugs that have opposite effects, or **antagonistic effects,** are administered together, each drug cancels the effect of the other. In other words, the actions of both drugs are nullified. An example of an antagonistic effect occurs when the adrenergic beta stimulant isoproterenol (Isuprel) and the adrenergic beta blocker propranolol (Inderal) are given together. Isoproterenol is a drug that is used in emergency situations to treat bradycardia, which is defined as a heart rate of less than 60 beats per minute. If given to a patient receiving a drug that decreases blood pressure and heart rate, the action of each drug is canceled. Neither drug delivers the expected therapeutic effect.

There are some situations in which the antagonistic effect is desirable. In morphine overdose, naloxone is given as an antagonist (antidote) to block the narcotic response. This is a beneficial drug interaction of an antagonist.

The use of two prescription drugs can have additive, synergistic, antagonistic, or no effect. This is especially true of warfarin; when taken with another drug, the effects of the second drug can increase, decrease, or have no effect on the anticoagulant. Table 4-3 lists the drugs that may be taken with an anticoagulant and the effects that the second drug has on the anticoagulant.

Table 4-4 summarizes the drug responses associated with pharmacodynamic interactions, and Table 4-5 lists selected drug-drug interactions.

TABLE 4-3 DRUG INTERACTIONS WITH ANTICOAGULANTS AND PRESCRIPTION DRUGS

PRESCRIPTION DRUGS	ANTICOAGULANT EFFECTS
Selected Antilipidemics	
Fibrate Group	Increased effect; may cause increased bleeding
Statin Group	
Lovastatin	Increased effect
Pravastatin	No known effects
Angiotensin-Converting Enzyme Inhibitors	No known effects
Aminoglycosides	No known effects
Aspirin	Strong effects; can cause bleeding
Antineoplastic Drugs	
Cytoxan, 5-fluorouracil, methotrexate, doxorubicin, vincristine	Increased effects; can cause bleeding
Cytoxan, mercaptopurine, mitotane	Decreased effects; Cytoxan may cause increased or decreased effects
Barbiturates	Reduced effect of anticoagulants
Benzodiazepines	No known effects
Beta Blockers	No known effects
Selected Cephalosporins	
Cefamandole	Increased effects; may cause bleeding
Nonsteroidal Antiinflammatory Drugs (NSAIDs)	
Ibuprofen	Normal doses; no effects
Diclofenac, ketoprofen, tolmetin	May increase effects
Quinolone Antibiotics	Usually no effects
Ciprofloxacin, norfloxacin, ofloxacin	Increased effects in isolated cases
Sulfonamides	
Bactrim-cotrimoxazole	Increased effects in 35% of persons
Tricyclic Antidepressants	No known effects
Vitamin K	Decreased effects of anticoagulants
Food	
Aspartame (artificial sweetener)	Increased effects
Green vegetables (spinach, broccoli, brussels sprouts)	Decreased effects; vegetables are rich in vitamin K
Alcohol	
Mild to moderate drinking	No effects unless heavy drinking
Heavy drinking	Increased effects if liver function is impaired

TABLE 4-4 PHARMACODYNAMIC INTERACTIONS OF DRUGS

INTERACTION	EFFECT
Additive	In the same drug category, the drug effect is the sum of both drug effects.
Synergistic or potentiation	One drug potentiates or enhances the effect of the other drug (greater than the effect of each drug alone).
Antagonistic	Two drugs in opposing drug categories cancel the effects of both drugs.

Common symptoms of drug-drug interactions include nausea, GI upset, headache, and dizziness. The patient should contact the pharmacist or health care provider if he or she experiences any unusual reaction. The most feared interactions are those that result in a dramatic drop in blood pressure or cause a rapid or irregular heart rate. Also of concern are drug interactions that produce toxins that may damage vital organs such as the heart or liver. Fortunately, most interactions are not severe or life threatening. Patients should be aware that prescription and OTC drugs and herbal products can interact with each other. It is a myth that interactions occur only with prescription medications. Severe adverse reactions are highlighted with a boxed warning in the product literature.

DRUG-FOOD INTERACTIONS

Food is known to increase, decrease, or delay drug absorption. Food can bind with drugs, causing less or slower drug absorption. An example of food binding with a drug is the interaction of tetracycline and dairy products. The result is a decrease in the plasma concentration of tetracycline. Because of the binding effect, tetracycline should be taken 1 hour before or 2 hours after meals and should not be taken with dairy products. Another example is levothyroxine, an antithyroid used to treat hypothyroidism. The absorption of this drug is erratic in the presence of food.

Food may also have an impact on the absorption of different dosage forms of the same drug. Antifungal itraconazole solution (Sporanox) is best absorbed on an empty stomach. However, itraconazole capsules, which require an acidic environment for absorption, have a higher availability when administered with food. Other examples in which food increases drug absorption include the antibiotic nitrofurantoin (Macrodantin), the beta blocker metoprolol (Lopressor), and the cholesterol-lowering drug lovastatin (Mevacor). These drugs should be taken with food. The composition of a meal may also influence drug absorption. For example, the absorption of levodopa, one of the components of the antiparkinsonism drug Sinemet, is significantly reduced when it is taken with high-protein meals.

The classic drug-food interaction occurs when an antidepressant of the monoamine oxidase inhibitor (MAOI) type (e.g., phenelzine) is taken with tyramine-rich foods such as cheese, wine, organ meats, beer, yogurt, sour cream, or bananas. These foods have sympathomimetic-like effects; more norepinephrine is released, and the result could be a hypertensive crisis. These foods must be avoided when taking MAOIs.

DRUG-LABORATORY INTERACTIONS

Abnormal plasma or serum electrolyte concentrations can affect certain drug therapies. If the patient takes digoxin and serum potassium and serum magnesium levels are decreased or serum calcium level is increased, digitalis toxicity may result. Drugs from the thiazide diuretic group can cause abnormal electrolyte concentrations. An example is hydrochlorothiazide, which can decrease serum potassium, magnesium, and sodium levels and can increase serum calcium levels. Hydrochlorothiazide promotes potassium loss, and low serum potassium results in an increase in the uptake of digoxin by myocardial tissue. This sensitization of the myocardium to digoxin increases the risk of digitalis-induced arrhythmias. When digoxin and hydrochlorothiazide are taken together, the nurse should observe the patient for digitalis toxicity. Symptoms are nausea, vomiting, bradycardia, and stated visual problems. Patients on long-term therapy should have regular digoxin levels drawn to detect early toxicity.

DRUG-INDUCED PHOTOSENSITIVITY

A drug-induced **photosensitivity** reaction is a skin reaction caused by exposure to sunlight. It is caused by the interaction of a drug and exposure to ultraviolet A (UVA) light, which can cause cellular damage. Usually the skin area that is exposed is affected.

There are two types of photosensitivity reactions: photoallergy and phototoxicity. Photoallergy occurs when a drug (e.g., sulfonamide) undergoes activation in the skin by ultraviolet light to a compound that is more allergenic than the parent compound. Because it takes time to develop antibodies, photoallergenic reactions are a type of delayed hypersensitivity reaction. With phototoxicity, a photosensitive drug undergoes photochemical reactions within the skin to cause damage. This type of reaction is different from photoallergy in that it is not immune-mediated. The onset of phototoxicity with erythema can be rapid, occurring within 2 to 6 hours of sunlight exposure.

Both types of reactions are the result of light exposure, but they differ according to the wavelength of light and the photosensitive drug. Phototoxicity may be the result of the drug dose, whereas photoallergenic reactions are not and only require previous exposure, or sensitization, to the offending agent. Examples of drugs that can induce photosensitivity are listed in Table 4-6.

Most photosensitive reactions can be avoided by using sunscreen with a sun protection factor (SPF) greater than 15; avoiding excessive sunlight, especially at the height of the daylight hours; and wearing protective clothing. Decreasing

TABLE 4-5 SELECTED DRUG-DRUG INTERACTIONS

DRUGS AND DRUG CATEGORIES	INTERACTING EFFECTS WITH DRUGS
Acyclovir	IV incompatible with dobutamine, dopamine, and morphine.
Alteplase	IV incompatible with dobutamine, dopamine, heparin, morphine, and nitroglycerin.
Aminoglycosides	Cephalosporins, ethacrynic acid, furosemide, polymyxin, and vancomycin can increase the risk of nephrotoxicity and ototoxicity. This is especially true in young and older adults.
Aminophylline	IV incompatible with dobutamine, dopamine, meperidine, and ondansetron.
Angiotensin-converting enzyme (ACE) inhibitors (e.g., captopril)	Antacids decrease absorption of ACE inhibitors. Potassium-sparing diuretics decrease potassium excretion, and lithium use decreases lithium excretion. Antihypertensives, nitrates, and diuretics enhance hypotensive effects.
Anticoagulants (e.g., warfarin [Coumadin])	Drugs that may enhance anticoagulant effects include acetaminophen (high doses), alcohol, antiplatelet drugs, aspirin, aminoglycosides, cephalosporins, erythromycins, furosemide, fluoroquinolones, isoniazid, NSAIDs, sulfonamides, thiazides, tricyclic antidepressants, and vitamin E.
Anticonvulsants (e.g., phenytoin [Dilantin])	Alcohol decreases phenytoin effect. Warfarin absorption may be decreased. May decrease effectiveness of oral contraceptives and corticosteroids. Isoniazid increases phenytoin levels.
Antipsychotic agents (e.g., phenothiazides)	Alcohol increases CNS depression. Antacids and antidiarrheals decrease drug absorption. Tricyclic antidepressants may increase the risk of hypotension. Anticonvulsant dose may need to be increased because phenothiazides can decrease seizure threshold.
Antitubercular agents (e.g., isoniazid)	Alcohol increases the risk of hepatotoxicity. Antacids decrease absorption of isoniazid. Phenytoin levels can increase, resulting in phenytoin toxicity.
Aspirin (salicylates)	Anticoagulants can increase the risk of bleeding when taken with aspirin. Oral antidiabetic agents may increase the risk of hypoglycemia.
Benzodiazepines (e.g., diazepam, lorazepam)	Alcohol, narcotics, and anticonvulsants can increase CNS depression. Cimetidine can increase diazepam and lorazepam toxicity. May decrease levodopa effects. May increase phenytoin serum levels.
Beta (adrenergic) blockers (e.g., propranolol [Inderal])	Diuretics, antihypertensives, and phenothiazines can increase the state of hypotension. Atropine can correct bradycardia. Antacids decrease propranolol absorption. Cimetidine decreases drug clearance and increases beta blocker effects.
Calcium channel blockers (e.g., nifedipine [Procardia])	May increase digoxin levels. Beta blockers have an additive effect and can cause bradycardia. H_2 blockers decrease drug clearance, resulting in elevated calcium blocker levels.
Cardiac glycosides (e.g., digoxin [Lanoxin])	Thiazide and loop diuretics, corticosteroids, laxatives, and amphotericin B can cause hypokalemia, which may cause digitalis toxicity. Antacids, antidiarrheals, and colestipol decrease absorption of digoxin. Quinidine, verapamil, and erythromycin increase digoxin levels.
Diazepam	IV incompatible with dobutamine, heparin, meperidine, and potassium in D_5W.
Diuretics (potassium-wasting) (thiazide and loop)	Digoxin toxicity may result from hypokalemia because of loop or thiazide diuretics. Corticosteroids increase potassium loss. May increase lithium levels.
Fluoroquinolones (e.g., ciprofloxacin [Cipro])	May increase theophylline and warfarin (Coumadin) levels. Antacids and iron products can decrease ciprofloxacin absorption.
Furosemide	IV incompatible with dobutamine, meperidine, morphine, and ondansetron.
Lithium carbonate	Diuretics, NSAIDs, tetracyclines, and methyldopa can increase lithium toxicity. Theophylline, sodium bicarbonate, and potassium or sodium citrate can promote lithium excretion.
Narcotics (e.g., morphine and meperidine [Demerol])	Alcohol, sedatives, benzodiazepines, barbiturates, and tricyclic antidepressants can increase CNS depression. Monoamine oxidase inhibitors (MAOIs) may cause hypertensive crisis.
Nonsteroidal antiinflammatory drugs (NSAIDs) (e.g., ibuprofen [Motrin])	Warfarin, heparin, and alcohol may prolong bleeding time. May increase lithium and methotrexate levels, resulting in lithium toxicity. Corticosteroids may cause peptic ulcer.
Penicillins	May decrease warfarin effects. NSAIDs prolong the effects of penicillin. Diuretics with penicillin G-K may cause hyperkalemia. May decrease effectiveness of oral contraceptives. Rifampin inhibits the action of penicillin.
Phenytoin	IV incompatible with dobutamine, heparin, meperidine, morphine, nitroglycerin, and potassium in D_5W.
Sulfonylureas	Alcohol, aspirin, anticoagulants, some NSAIDs, anticonvulsants, sulfonamides, and oral contraceptives may increase the risk of hypoglycemia. Corticosteroids, thiazide diuretics, estrogen, calcium channel blockers, phenytoin, and thyroid drugs may increase the blood sugar level.
Tetracyclines	Milk, antacids, and iron supplements decrease tetracycline absorption. May decrease effectiveness of oral contraceptives.
Theophylline	Erythromycins, fluoroquinolones, and tacrine can increase theophylline levels. May increase lithium excretion. Cigarette smoking decreases theophylline levels.
Tricyclic antidepressants (e.g., amitriptyline)	Can increase anticoagulant effects of warfarin. Alcohol, narcotics, and sedatives increase CNS depression. MAOIs must not be taken with tricyclic antidepressants. May reduce antihypertensive drug effects. Cimetidine may increase tricyclic serum levels.

TABLE 4-6 DRUG-INDUCED PHOTOSENSITIVITY

DRUG-INDUCED	OCCURRENCE
Amantadine	Confirmed by positive photopatch testing.
Amiodarone	Frequency may be 10% to 75%. Sunscreen lotion with UVA can help reduce incidence.
Benzodiazepines	Reported cases with alprazolam and chlordiazepoxide.
Carbamazepine	Frequency is less than 1%; however, photocopy machines can trigger photosensitivity.
Corticosteroids	Reported cases with positive photopatch testing and with use of hydrocortisone.
Fluorouracil	Avoid sunlight with topical or intravenous use; erythema and hyperpigmentation may occur.
NSAIDs	Aspirin, ibuprofen, and indomethacin have been reported to have a low phototoxic effect; however, there is a possibility for a dose-related photosensitive effect with ibuprofen.
Methotrexate	Avoid sunlight to prevent severe photosensitive reaction (sunburn).
Calcium blockers	Diltiazem: possible phototoxic reaction nifedipine: may cause phototoxicity with high doses.
Phenothiazines	Reported cases of phototoxic reaction with chlorpromazine and other phenothiazines at high drug doses.
Piroxicam	Was confirmed with positive photopatch testing; photosensitive reaction occurs after a few days of piroxicam and exposure to sunlight.
Pyrazinamide	Skin color may change to reddish brown; usually occurrence is dose-related.
Quinolones (fluoroquinolones)	Phototoxicity occurs with lomefloxacin, enoxacin, ofloxacin, and nalidixic acid; ciprofloxacin causes less photosensitivity.
Sulfonamides	Reported cases of photosensitive reaction.
Sulfonylureas	Reported cases of photosensitive reaction.
Tetracyclines	Highly photosensitive; demeclocycline and doxycycline have a higher degree of photosensitive reaction than minocycline.
Thiazides	Thiazide-induced photosensitivity has been reported; hydrochlorothiazide has a greater photosensitivity than bendroflumethiazide.
Trimethoprim	Reported cases of photosensitive reaction.
Vinblastine	Reported cases of photosensitive reaction.

NSAID, Nonsteroidal antiinflammatory drug; *UVA,* ultraviolet A.

the drug dose may decrease the risk of photosensitivity if treatment is required. It may be necessary, however, to discontinue use of the offending drug.

OVER-THE-COUNTER DRUGS

OTC drugs are found in most households. According to the U.S. Food and Drug Administration (FDA), OTC drugs have been found to be safe and appropriate for use without the supervision of a health care provider, and individuals can access them without a prescription. More than 90% of illnesses are initially treated with OTC drugs, and their use is unknown to many health care providers. A study of 7 resident physicians and 414 adult patients revealed that more than 50% of the patients reported OTC use, and physicians questioned OTC use in 33% of the visits. Almost 60% of those reporting OTC use did not tell the physician; at the same time, only 14% of the patients indicated it was not important to report OTC use to the physician.

Many drugs that were previously available only by prescription are available OTC. Examples include proton pump inhibitors (e.g., Prilosec-OTC) and Plan B® emergency contraception. Knowing all of the medications a patient is taking is an important part of the nursing history. For example, aspirin can increase the risk of bleeding if the patient is taking anticoagulants such as warfarin. The nurse needs to reconcile medications as part of the patient safety standards on admission to the hospital; this includes both prescription medications and OTC drugs (e.g., baby aspirin 81 mg for patients with coronary artery disease). (Refer to Chapter 12 for discussion of medication reconciliation.)

Many factors contribute to the increase in the number and use of OTC products. Mass-media marketing of drugs surrounds us. Many people turn to "self-treatment" because they lack the time, money, or health insurance for regular doctor visits. It is one of the nurse's responsibilities to advocate for the patient making educated choices.

OTC drugs include vitamin supplements, cold and cough remedies, analgesics for pain, antacids, laxatives, antihistamines, sleep aids, nasal sprays, weight-control drugs, and herbal products. Some patients do not consider herbal products to be OTC drugs. More than $4 billion is spent annually on herbal products, nutraceuticals, and dietary supplements; most of these products are minimally regulated by the FDA. (Refer to Chapter 6 for a discussion of herbal therapies.)

The FDA has been working to standardize OTC labeling. OTC labeling is designed to provide consumers with better information and to describe the benefits and risks associated with taking OTC medications. Multiple OTC drugs may have the same active ingredients; patients should avoid taking an excess amount of an ingredient.

Nurses must be aware of OTC products and the implications of their use for their patients' drug therapy. OTC drugs provide both advantages and potential serious complications for the consumer. The nurse needs to emphasize that many of these drugs are potent medications and can cause moderate to severe side effects, especially when taken with other drugs. Self-diagnosis and self-prescribing OTC drugs may mask the seriousness of a clinical condition. Based on an increase in serious adverse reactions and deaths of infants and toddlers, the FDA recalled all OTC medications with directions/dosages for children 2 years of age and younger in 2007. Refer to Chapter 2 for detailed information on drug regulation.

The FDA has the responsibility for monitoring the safety of drug therapy and is charged with identifying standards for known active ingredients and establishing mandatory

BOX 4-1 FDA OVER-THE-COUNTER DRUG CATEGORIES

- Allergy treatment products (internal)
- Analgesics—antipyretics (internal)
- Antacids and antiflatulents
- Antidiarrheal products
- Antimicrobials
- Antiperspirants
- Antirheumatic products
- Antitussives
- Bronchodilators and antiasthmatic products
- Cold remedies and decongestants
- Contraceptive products
- Dandruff products
- Dentifrices and other dental products
- Dermatologic products
- Emetics and antiemetics
- Hematinics
- Hemorrhoidal products
- Herbal products
- Laxatives and cathartics
- Nicotine gum or transdermal patches
- Ophthalmic products
- Oral-hygiene drug products
- Sedatives and sleep aids
- Stimulants
- Sunburn prevention and treatment products
- Vitamin-mineral supplements
- Weight-control aids
- Miscellaneous products (not covered in above categories)

FDA, U.S. Food and Drug Administration.

labeling to assist consumers in the proper use of drugs. The FDA OTC drug categories are listed in Box 4-1.

As a result of review by the FDA, drugs are placed in one of three categories:

- Category I: Drugs judged to be both safe and effective
- Category II: Drugs judged to be either unsafe or ineffective; these drugs should not be included in nonprescription products
- Category III: Drugs for which there are insufficient data to judge safety or efficacy

The FDA has recommended that drugs in category II be reformulated to be included in category I or removed from the market. (Manufacturers can maintain the brand name after changing the components of an OTC product.)

The FDA has also recommended that selected prescription drugs be reclassified so they can be sold OTC. For example, the prescription drug Motrin became available as the OTC drug ibuprofen in 1984; Tagamet, another prescription drug, was made available as the OTC drug cimetidine. Because of this process, hundreds of thousands of OTC products have ingredients or dose strengths that were once available only by prescription. As a result, it is vitally important that nurses be aware of current drug information, any changes in FDA recommendations, and the implications of this information for an informed patient population. The following cautions may be of assistance when OTC preparations are considered:

- Delay in professional diagnosis and treatment of serious or potentially serious conditions may occur if the patient self-prescribes OTC drugs.
- Symptoms may be masked, making diagnosis more complicated.
- Labels and instructions should be followed carefully.
- The patient's health care provider or pharmacist must be consulted before OTC preparations are taken.
- Ingredients in OTC products may interact with medications prescribed by the health care provider or self-prescribed by the patient.
- Inactive ingredients (e.g., alcohol, dyes, preservatives) may result in adverse reactions.
- Potential for overdose exists because of the use of several preparations with similar active ingredients. A double dose does not translate into a quicker recovery.
- The risk for adverse drug reactions and drug-drug interactions will increase as more medications, whether prescription or OTC, are added to drug therapy regimens.

Interactions of selected prescription medications and OTC preparations are potentially dangerous. Many individuals routinely reach for aspirin, acetaminophen, and ibuprofen to relieve discomfort or pain without being aware of these interactions. For example, ibuprofen increases fluid retention, which could worsen the condition of a patient with heart failure; use of ibuprofen on a long-term basis may decrease the effectiveness of antihypertensive drugs.

Several OTC drugs, such as cough and cold preparations, are composed of two to four compounds. For patients who are already taking maintenance medicine, it is conceivable that there could be a drug-drug interaction with a cough medicine and one of the medications prescribed by the patient's health care provider.

Patients with asthma should be aware that aspirin can trigger an acute asthma episode. Patients may be allergic to aspirin, or aspirin may act as a deregulator of leukotrienes. Aspirin is also not recommended for children with influenza symptoms or chickenpox, because it has been associated with Reye syndrome. Patients with impaired renal function should avoid aspirin, acetaminophen, and ibuprofen because each can further decrease renal function, especially with long-term use. Also, patients taking moderate to high doses of aspirin, ibuprofen, or naproxen concurrently with an oral anticoagulant may be at increased risk for bleeding.

The previous examples are not all-inclusive. Caution is advised before using any OTC preparation, including antacids, decongestants, and laxatives. Patients should check with their health care providers and read drug labels before taking OTC medications so they are aware of possible contraindications and adverse reactions. They should look for product name, active ingredients, purpose, uses, warnings, directions, storage information, and inactive ingredients (e.g., color, flavors). The acronym SAFER is a mnemonic for the instructions that the FDA recommends before taking any medicine: **S**peak up, **A**sk questions, **F**ind the facts, **E**valuate your choices, and **R**ead the labels. (Refer to Chapter 12 for a comprehensive discussion of medication safety.)

Polypharmacy is a problem in the United States, and older adults are especially at risk. (Refer to Chapter 8 for more information on geriatric pharmacology.)

A good source for OTC drug information is *The Handbook of Nonprescription Drugs,* published by the American Pharmacists Association in Washington, DC. The Internet can be another great resource if only credible sites are used. Key websites are listed at the end of this chapter.

Cough and Cold Remedies

Most OTC cough and cold remedies are used to relieve coughs and nasal and sinus congestion. These products contain ingredients such as guaifenesin, dextromethorphan, pseudoephedrine, an analgesic, and an antihistamine.

The majority of ingredients to treat nasal congestion are sympathomimetic (i.e., they stimulate the sympathetic nervous system). Examples include phenylephrine and pseudoephedrine. The FDA has ordered removal of phenylpropanolamine from OTC cold remedies because of the increased risk of hemorrhagic stroke in young women who take the drug. It has been reported that phenylpropanolamine may also cause psychosis, hypertension, renal failure, and cardiac dysrhythmias.

OTC cough and cold remedies are primarily safe for children older than 6 years. For children ages 2 to 6 years, consult with a health care provider. The use of these medications in children younger than 2 years is not recommended. In fact, the Centers for Disease Control and Prevention (CDC) has reported that cough and cold medications can be harmful and should be used with caution in children younger than 2 years. This statement was issued in response to the discovery of three infant deaths in 2005 from the toxic effects of these medications. The report stated that more than 1500 emergency department visits in 2004 and 2005 were due to adverse effects associated with cough and cold medication use in children younger than 2 years.

Patients with heart disease, hypertension, or thyroid disease should not take these OTC preparations without approval from their health care provider. Side effects of cough and cold OTC drugs that contain a sympathomimetic include headache, nervousness, increased blood pressure, and insomnia. The most common side effect of the antihistamine is drowsiness.

Health professionals should discuss the pros and cons of taking cough and cold remedies with their patients and read labels carefully. The recommended dose should not be exceeded for either adults or children. Iatrogenic conditions (treatment-induced disorders) are another concern. In situations with limited choices in pharmacotherapy, the patient and the health care provider at times have to deal with a second condition resulting from the treatment with a particular drug. An example of an iatrogenic condition is when a person medicated with antiinflammatory steroids develops a Cushing's appearance. People on long-term acetylsalicylic acid (ASA) therapy are prone to developing ulcers.

Sleep Aids

The FDA restricts the number of OTC sleep aids available. Before 1979, most OTC sleep aids contained bromides, scopolamine, or a combination of antihistamines. Now, most OTC sleep aids contain an antihistamine with or without an analgesic such as aspirin or acetaminophen (e.g., Tylenol PM). The side effect of an antihistamine is drowsiness, which is useful as a sleep aid. If the patient has night pain that causes sleeplessness, an analgesic with antihistamine is helpful. In young children or older adults, these sleep aids may cause CNS stimulation instead of sedation. These drugs should not be taken with a depressant because they can have an additive depressive effect on the CNS.

Weight-Control Drugs

For years, most weight-control drugs contained amphetamines. They were prescription drugs prescribed to suppress the appetite. The effectiveness of the amphetamines was short-term because they were effective only as long as the therapeutic blood level of the drug was maintained. Side effects included nervousness, heart palpitations, increased blood pressure, and insomnia. Drug dependence was a problem associated with amphetamines. They are no longer used in weight-control preparations.

Currently, many OTC weight-control products are on the market. They are contraindicated for patients with heart disease, hypertension, diabetes mellitus, and thyroid disease, and their effectiveness is not proven.

In February 2007, the FDA approved the marketing of orlistat (Alli) as an OTC weight-control medication. Alli was the first FDA-approved weight-control medication to be sold in the United States without a prescription; it inhibits lipase enzymes within the GI tract and blocks the dietary absorption of fat by about 30%. For use in adults age 18 years and older, it is to be used as part of a weight-control program that includes a reduced-calorie, low-fat diet and an exercise program. A daily multivitamin should be taken when orlistat is used. The most common side effects of orlistat are oily spotting on underwear, flatulence, urgent bowel movements, and fatty or oily stools. Additionally, in May 2010, the FDA announced that rare cases of serious liver injury have been reported with use of prescription and OTC orlistat. Symptoms of possible liver failure include weakness or fatigue, fever, jaundice, brown urine, abdominal pain, nausea, vomiting, light-colored stools, itching, and loss of appetite.

Nursing Process
Patient-Centered Collaborative Care

Drug Interactions

Assessment

- Obtain a medication history on your patient. Include questions regarding OTC drug and herbal product use.

There could be a drug interaction with the prescribed drug.
- Review all literature provided by drug companies and pharmacy.
- Assess for drug reaction when two highly protein-bound drugs are taken together daily. For example, the anticoagulant warfarin (Coumadin) and the anticonvulsant phenytoin have a high affinity to protein. When warfarin is displaced from the plasma protein binding sites, this leads to more free warfarin and a possible increase in bleeding risk.
- Determine the potential for drug interaction problems related to an increased or decreased absorption rate of two drugs. Drug enzyme inducers that increase the metabolism of an affected drug may result in a decrease in effect of that drug.
- Assess the patient for drug toxicity when a drug enzyme inducer has been discontinued or when a drug enzyme inhibitor is taken concurrently with other drugs.
- Determine whether or not the patient is a cigarette smoker. Tobacco is an enzyme inducer and can increase the metabolic rate of drugs. If patient is a smoker and is taking a drug such as theophylline to control asthma, the drug dosage may need to be increased. For nonsmokers, the theophylline dosage should be within the suggested drug dosing range.
- Determine renal function by checking for adequate urine output; it should be greater than 600 mL daily. The guideline is 30 mL/hr for adults.

Nursing Diagnoses
- Readiness for enhanced knowledge related to therapeutic regimen
- Deficient knowledge related to lack of information about drug interactions and OTC drugs
- Risk for injury related to adverse reaction to drug interaction

Planning
- Patient will be aware of drug interactions, will avoid drugs that may cause a severe reaction, and will know what to report immediately to the health care provider.
- Patient will not take any OTC drugs without consultation with the health care provider.

Nursing Interventions
- Contact the health care provider to assess the need for a drug dose adjustment if one has not been ordered after a drug enzyme inducer has been discontinued.
- Recognize drugs of the same category that might have an additive effect. The additive drug effect might be undesirable and could cause a severe physiologic response.
- Notify the health care provider of drugs ordered that have antagonistic or opposite effects, such as beta stimulants and beta blockers.
- Consult a pharmacist about the use of a drug interaction computer program.
- Encourage the patient to use one pharmacy; drug reconciliation is to be done for hospitalized patients and patients on community-based visits to the health care provider.

Patient Teaching
- Advise patients not to take OTC drugs with prescribed drugs without first notifying the health care provider.
- Remind patients to be cautious about taking herbal products, especially if taking OTC or prescription medications; check with health care provider first.

Evaluation
- Evaluate the effectiveness of the drugs, and determine that patient is free from side effects.

CRITICAL THINKING CASE STUDY

A patient is taking phenytoin, warfarin (Coumadin), promethazine, (Phenergan), meperidine (Demerol), and diazepam (Valium).

1. What general teaching is appropriate for this patient? Be certain to include specifics about probable drug interactions.
2. During a teaching session, the patient shares that he plans to start taking OTC products to boost his energy. What is the nurse's best response to the patient's comment? Explain your answer.

NCLEX STUDY QUESTIONS

1. The rate of absorption of drugs can change when two drugs are taken at the same time. The nurse is aware that the rate of absorption can be changed by which actions? (Select all that apply.)
   - a. Modifying gastric emptying time
   - b. Changing gastric pH
   - c. Decreasing inflammation
   - d. Forming drug complexes
   - e. Eating too slowly
2. The nurse is reviewing a patient's medications as part of patient teaching. The nurse is aware that which drug is least likely to cause photosensitivity?
   - a. Penicillins
   - b. Sulfonamides
   - c. Sulfonylureas
   - d. Thiazides
3. A patient asks the nurse about the drug qualities that determine the category in which a drug is placed. What is the nurse's best response? (Select all that apply.)
   - a. "Drugs that are in clinical trials"
   - b. "Drugs judged to be both safe and effective"
   - c. "Drugs judged to be either unsafe or ineffective"
   - d. "Drugs with insufficient data to judge safety or efficacy"
   - e. "Herbal products"
4. The nurse is meeting with a community group about medication safety. The nurse must emphasize that patients at high risk for drug interactions include which groups? (Select all that apply.)
   - a. Older patients
   - b. Patients with chronic health conditions
   - c. Patients taking three or more drugs
   - d. Patients dealing with only one pharmacy
   - e. Patients covered by Medicare or Medicaid
5. The nurse recognizes that when a patient takes a hepatic enzyme inducer, the dose of the warfarin (Coumadin) is usually modified in which way?
   - a. It is increased.
   - b. It is decreased.
   - c. It remains the same.
   - d. It is unpredictable.
6. The nurse is conducting a patient assessment and notes that the patient has alkaline urine, which promotes excretion of drugs that are weak acids. Which drug is a weak acid?
   - a. phenytoin (Dilantin)
   - b. acetylsalicylic acid (aspirin)
   - c. quinidine (Apo-Quinidine)
   - d. warfarin (Coumadin)
7. The nurse is describing to a patient the synergistic effects of two of his medications. Which statement by the nurse is correct about synergistic drug effects?
   - a. "Two drugs have antagonistic effects on each other."
   - b. "The action of a drug is nullified by another drug."
   - c. "One drug acts as an antidote to the side effects of another drug."
   - d. "A greater effect is achieved when two drugs are combined."
8. A patient asks the nurse about cautions related to use of OTC medications. What is the nurse's best response? (Select all that apply.)
   - a. "Over-the-counter drugs may delay professional diagnosis."
   - b. "They may mask symptoms."
   - c. "They may make diagnosis easier."
   - d. "Their inactive ingredients may cause adverse reactions."
   - e. "They may be more expensive."
9. Patients on long-term digoxin (Lanoxin) therapy need regular digoxin-level monitoring to detect early toxicity manifested by which symptoms? (Select all that apply.)
   - a. Visual problems
   - b. Nausea and vomiting
   - c. Skin eruptions
   - d. Urinary retention
   - e. Dizziness
10. The nurse is reviewing a teaching plan with a patient who was recently diagnosed with asthma. What cautions about the use of aspirin are important for the nurse to advise the patient? (Select all that apply.)
    - a. It may trigger an acute asthma attack.
    - b. It may trigger a heart attack.
    - c. There is an increased risk for bleeding if also taking an anticoagulant.
    - d. It may decrease renal function.
    - e. It may decrease hepatic function.
11. A patient asks the nurse about drug interactions with OTC preparations. What is the nurse's best response?
    - a. "Discuss this with the health care provider."
    - b. "There are not many interactions, so don't worry about it."
    - c. "Read the labels carefully, and check with your health care provider."
    - d. "Avoid over-the-counter preparations."

Answers: 1, a, b, d; 2, a; 3, b, c, d; 4, a, b, c; 5, a; 6, b; 7, d; 8, a, b, d; 9 a, b, d; 10 a, c, d; 11, c.

OBJECTIVES

- Define and differentiate among drug abuse, drug misuse, addiction, dependence, tolerance, detoxification, withdrawal, and abstinence.
- Describe the short-term and long-term effects of the relationships among brain structures and neurotransmitters involved in the neurobiology of addictive drugs.
- Identify the physical and psychological assessment findings associated with the use of commonly abused central nervous system stimulants and depressants, cannabis, psychedelic agents, and inhalants.
- Explain the rationale for the use of pharmacologic treatments during toxicity, withdrawal, and maintenance of abstinence of commonly abused drugs.
- Prioritize appropriate nursing interventions to use during treatment of patients with substance toxicity and withdrawal.
- Identify nursing interventions appropriate during management of surgical experiences and pain in patients who abuse drugs.
- Describe the nurse's role in recognizing and promoting treatment of chemical impairment among nurses.
- Implement the nursing process in the care of patients who abuse drugs.

Most drugs are used safely and within prescribed guidelines, but it is possible for all drugs to be misused or abused. Drug abuse and addiction are serious and complex social and health problems that nurses address in all areas of practice. However, this chapter focuses primarily on the physiologic effects of abused drugs and the pharmacologic treatment of abuse.

CONTEXT OF DRUG ABUSE

Cultural Considerations

Cultural and social expectations influence the definitions and perception of drug abuse versus acceptable usage. In Moslem Middle Eastern populations, any use of alcohol or mind-altering drugs may be considered abuse. The same might be true in the United States among conservative religious groups. Yet in many European cultures, alcohol use is expected and present at all family and social gatherings. For many people in the United States, occasional use of marijuana and alcohol is not considered abuse, nor is the use of psychedelic agents in some Native American religious rites. Cigarette smoking, which was glamorized in the past, is now less socially acceptable than moderate alcohol use in the United States.

Sociocultural factors arising from unemployment, poverty, or adverse social conditions affect the incidence of substance abuse. Individual factors, such as age, educational status, and geographic region, also affect rates of use. Metropolitan and urban areas have higher rates of substance abuse than rural areas in the United States. Additionally, the West Coast has a higher rate of use (11.0%) than the Northeast, Midwest, or South (9.4%, 8.2%, and 7.8%, respectively). A major responsibility of nurses in addressing drug abuse in ethnic and cultural groups is to assess and treat patients within their cultural perspectives, as described in Chapter 3.

Definitions

Although small differences exist in their definitions, the terms *drug, substance,* and *chemical* are often used interchangeably within the context of drug abuse. **Drug misuse** generally refers to indiscriminate or recreational use of a chemical substance or its use for purposes other than those for which it is intended. **Drug abuse** is culturally defined and may be considered drug use inconsistent with medical or social norms. It generally refers to an overindulgence of a chemical substance that results in a negative impact on the psychological, physical, or social functioning of an individual. Chronic abuse of a drug may lead to addiction. **Drug addiction** should be considered a complex disease of the central nervous system (CNS) characterized by a compulsive, uncontrolled craving for and **dependence** on a substance to such a degree that cessation causes severe emotional, mental, and/or physiologic reactions. **Physical dependence** is not necessary or sufficient for addiction to occur. Terms used in describing drug abuse are presented in Table 5-1.

Drugs abused most often are psychoactive agents that result in pleasure or modify thinking and perception. They include legal substances such as alcohol, tobacco, and prescription drugs such as analgesics, sedative-hypnotics, tranquilizers, and amphetamines. Common illegal substances that are abused include marijuana and hashish, cocaine, MDMA, and heroin.

NEUROBIOLOGY OF ADDICTIVE DRUGS

Most addictive drugs increase the availability of dopamine and other neurotransmitters in the mesolimbic system of the brain. This area has been identified as the “pleasure center” or **brain reward system**, an ancient system that creates the sensation of pleasure for certain behaviors necessary for survival, such as eating and sexual behavior.

Normally dopamine is released at a stable rate in the mesolimbic system, maintaining a normative mood. Certain drugs such as opioids and cocaine increase the release of dopamine or decrease its reuptake at the synapse. Nicotine, alcohol, marijuana, amphetamines, and caffeine are also believed to increase dopamine activity at the synapse. The resulting increase in dopamine in the system leads to mood elevation or euphoria, factors that provide strong motivation to repeat the experience. Many addictive drugs also increase the availability of other neurotransmitters such as serotonin and gamma-aminobutyric acid (GABA), but dopamine's effect on the reward system appears to be pivotal to the addictive process.

Addiction (a compulsive, uncontrollable craving for and dependence on a substance to such a degree that cessation causes severe reactions) results from the prolonged effects of addictive drugs on the brain. Repeated use of drugs remodels the neural circuitry of the brain cells and reduces the responsiveness of receptors. This decreased responsiveness leads to

TABLE 5-1 **TERMINOLOGY OF DRUG ABUSE**

TERM	DEFINITION
Abstinence	Sustained avoidance of substance use.
Addiction	A compulsive, uncontrollable craving for and dependence on a substance to such a degree that cessation causes severe emotional, mental, or physiologic reactions.
Chemical impairment	A term used by health professionals to describe behaviors related to the effects of drugs or substances on performance.
Craving	Subjective need for a substance, usually experienced after decreased use or abstinence. Cue-induced craving is stimulated in the presence of situations previously associated with drug taking.
Dependence	Reliance on a substance that has reached the level that its absence will cause impairment in function.
Psychological	Compulsive need to experience pleasurable response from the substance.
Physical	Altered physiologic state from prolonged substance use; regular use is necessary to prevent withdrawal syndrome.
Drug abuse	Overindulgence in and dependence on a substance that has a negative impact on psychological, physiologic, and social functioning of an individual; synonymous with chemical dependence.
Drug misuse	Indiscriminate use of a drug for purposes other than those for which it is intended.
Relapse	Return to substance use during abstinence.
Substance	Drug, chemical, or biologic entity.
Tolerance	Decreased effect of a substance that results from repeated exposure. It is possible to develop cross-tolerance to other substances in the same category.
Withdrawal syndrome	Constellation of physiologic and psychological responses that occur when there is abrupt cessation or reduced intake of a substance on which an individual is dependent or when the effect is counteracted by a specific antagonist.

tolerance—the need for a larger dose of a drug to obtain the original euphoria. As drugs of abuse result in levels of dopamine that do not naturally occur, tolerance also reduces the sense of pleasure from experiences that previously resulted in positive feelings, such as food, sex, or relationships. Without the drug, the individual may experience depression, anxiety, and/or irritability. **Craving** is another characteristic of addiction; one type of craving is **cue-induced craving**, which occurs in the presence of people, places, or things patients have previously associated with drug use. These encounters produce surges in dopamine levels, and these surges push the individual toward active drug seeking and drug taking. Cue-induced craving may occur after long periods of **abstinence** and is a common cause of **relapse.**

Continued research into the biologic and genetic basis of addiction is crucial to the development of drugs to treat addiction. Increasing evidence shows that genetics play a significant role in alcoholism and nicotine use and that there are significant gender differences in drug abuse risk. A natural genetic mutation that inhibits nicotine metabolism in the brain has been identified. Men with the mutation are less likely to become addicted to nicotine and find it easier to quit smoking. However, the presence or absence of the defective gene does not affect women's smoking. Women also have less stomach metabolism of alcohol, resulting in higher blood alcohol levels than men after the same amount of alcohol intake. A genetic difference in the activity of a liver enzyme in African Americans results in slower metabolism of nicotine, potentially resulting in the consumption of fewer cigarettes per day than Caucasian people may consume.

Biologic and genetic research has led to the development of drugs to treat opioid, nicotine, and alcohol addiction. However, currently no medications are approved by the U.S Food and Drug Administration (FDA) for treating addiction to cocaine, lysergic acid diethylamide (LSD), phencyclidine hydrochloride (PCP), marijuana, methamphetamine and other stimulants, or inhalants.

OVERVIEW OF ADDICTIVE STATES

Intoxication

Intoxication is a state of being influenced, or affected by a drug or other toxic substance. This may be a very small amount of drug in the drug-naïve person, or a potentially lethal amount in the chronic user. The signs and symptoms seen for either are the toxic effects of the drug when taken in excessive amounts.

Detoxification

Detoxification involves treating an intoxicated patient to diminish or remove drugs or their effects from the body. Treatments may involve administration of antagonistic drugs, promotion of metabolism and elimination of the drug, or intensive supportive care until the drug is naturally eliminated.

Withdrawal Syndrome

Withdrawal syndrome is a group of signs and symptoms that occurs in physically dependent persons when drug use is stopped. The symptoms are often opposite the effects the drug produced before it was withdrawn. Opioids, alcohol, barbiturates, and anxiolytics cause relatively strong physical dependence and withdrawal syndrome. Cannabinoids and amphetamines cause weaker physical dependence. Hallucinogens such as LSD do not cause physical dependence or abstinence signs. Withdrawal syndrome is treated by slow weaning of the drugs, or use of "cross-tolerant" drugs to control symptoms, and supportive care.

Cessation and Maintenance of Abstinence

To promote cessation and abstinence of the abused drug, treatment with other drugs may be used to decrease craving and prevent withdrawal syndrome. Specific receptor blockers, less potent drugs of the same class, or nonaddicting substitutes are treatment options. In addition to the use of drugs to maintain abstinence, cognitive-behavioral therapies enhance the effectiveness of medications and are recommended for treatment of all drug abuse and addiction.

STIMULANTS

Nicotine

Nicotine is the alkaloid in tobacco that causes dependence and is the most rapidly addicting of the drugs of abuse. Smoking cigarettes is the most damaging method of nicotine use. Cigarette smoke contains more than 4000 chemicals and gases, including at least 45 cancer-causing or tumor-promoting agents and a number of hydrocarbons or solvents. Although nicotine is not believed to be carcinogenic, it is the addictive substance and has no therapeutic value.

Pharmacokinetics Nicotine is rapidly absorbed into the blood through the lungs in smoking and more slowly through the buccal mucosa in chewing and the nasal mucosa in snuffing. It crosses membranes easily and is widely distributed throughout the body. Nicotine passes freely into breast milk and may be toxic to the nursing infant. Plasma protein binding of nicotine is less than 5%. The liver is the major site of nicotine metabolism. Nicotine and its more than 20 metabolites are eliminated in the urine. The elimination half-life of nicotine is 1 to 2 hours.

Pharmacodynamics In low doses, such as those obtained through cigarettes, nicotine activates nicotinic receptors. Most effects occur from activated receptors in autonomic ganglia and the adrenal medulla. In the CNS, nicotine rapidly acts on the mesolimbic reward system of the brain, promoting the release of dopamine and mimicking the effects of cocaine and other highly addictive substances.

Side Effects and Adverse Reactions

Stimulation of nicotinic receptors in the sympathetic ganglia and the adrenal medulla result in marked cardiovascular stimulation and increased myocardial oxygen consumption. In the brain, the action of nicotine causes general CNS stimulation. Physical effects include increased respiratory rate and tremors. Psychological effects include increased alertness and arousal. In the gastrointestinal (GI) tract, nicotine increases GI secretions and smooth-muscle tone. Many abusers of nicotine report that nicotine has a depressant effect, promoting relaxation and relief of anxiety. However, it is thought that these effects actually occur when periodic nicotine withdrawal is relieved by further nicotine.

Nicotine causes a very strong **psychological dependence**. In addition, physiologic dependence occurs with regular heavy use. Withdrawal symptoms may occur within the first few hours after stopping smoking, peak in 24 to 48 hours, and last from a few weeks to several months. After withdrawal subsides, cue-induced craving may cause smoking relapse. The effects of nicotine and symptoms of withdrawal are presented in Table 5-2.

Treatment

Treatment of nicotine addiction has received considerable attention in the past few years because of its association with preventable illness and death. Chronic smoking can affect nearly every organ of the body. In addition to cardiovascular disease, chronic lung disease, and cancers of the larynx, lung, esophagus, oral cavity, and bladder, smoking is now associated with leukemia, cataracts, abdominal aortic aneurysm, and cancers of the cervix, kidney, pancreas, and stomach. To help end thousands of these unnecessary health problems, nurses must be proactive in identifying and talking with tobacco users and providing them with information on ways to stop the use of tobacco.

Several drug products are available to aid smoking cessation. Except in special circumstances, nicotine replacement therapy (NRT) or other smoking cessation agents are recommended for all tobacco users in addition to behavioral and support therapies. Five NRTs in the form of gum, lozenges, transdermal patches, nasal spray, and inhalers have been approved by the FDA to reduce the craving and withdrawal symptoms associated with tobacco cessation. These agents enable a smoker to reduce nicotine previously obtained from cigarettes with a system that provides slower delivery of the drug and eliminates the carcinogens and gases associated with tobacco smoke. Table 5-3 describes various nicotine replacement products.

Bupropion is an atypical (heterocyclic) antidepressant unrelated to nicotine that has been approved by the FDA for smoking cessation. The exact mechanism of action of bupropion is unknown. It is thought to inhibit neuronal reuptake of dopamine, and to a lesser degree norepinephrine, and this reduces the urge to smoke and minimizes some symptoms of nicotine withdrawal. Bupropion may be combined with NRT to provide additional benefit. Bupropion is marketed as Zyban for smoking cessation. Serious negative effects of bupropion use include agitation, hostility, increased depression or other psychiatric symptoms, and suicidality.

Varenicline (Chantix) is a novel drug approved for smoking cessation that is an alternative to NRT and bupropion. It is a nicotinic receptor partial agonist that reduces cravings for nicotine and decreases the pleasurable effects of cigarettes and other tobacco products if tobacco is used. The approved course of varenicline treatment is 12 weeks, and those who successfully quit smoking during treatment may continue with an additional 12 weeks to increase long-term cessation. In clinical trials, the most common adverse effects were nausea, headache, vomiting, flatulence, insomnia, abnormal dreams, and a change in taste perception; serious negative effects are similar to those for bupropion.

Nortriptyline (Aventyl, Pamelor) and clonidine (Catapres) are used as second-line drugs to reduce nicotine withdrawal symptoms and promote cessation. These drugs are not approved by the FDA for this purpose, and their action in nicotine addiction is not clearly understood. Nortriptyline is a tricyclic antidepressant (see Chapter 28). Clonidine is a centrally acting alpha$_2$ agonist used to treat hypertension (see Chapter 44).

Research related to the development of new agents and new uses of approved drugs in smoking cessation is a priority of the National Institute for Drug Abuse. Clinical trials are currently in progress to examine the effects of various combinations of nicotine-replacement agents, combinations of nicotine-replacement agents with antidepressants, neurotransmitter modulators, nicotine vaccines that produce antibodies that bind in the blood with nicotine, and nicotine receptor–blocking agents. More information on nicotine

TABLE 5-2 EFFECTS OF FREQUENTLY ABUSED DRUGS

SUBSTANCE	PHYSIOLOGIC AND PSYCHOLOGICAL EFFECTS	TOXICITY	WITHDRAWAL SYNDROME
Stimulants			
Nicotine	Increased arousal and alertness; performance enhancement; increased heart rate, cardiac output, and blood pressure; cutaneous vasoconstriction; fine tremor, decreased appetite; antidiuretic effect; increased gastric motility	Rare: Nausea, abdominal pain, diarrhea, vomiting, dizziness, weakness, confusion, decreased respirations, seizures, death from respiratory failure	Craving, restlessness, depression, hyperirritability, headache, insomnia, decreased blood pressure and heart rate, increased appetite
Cocaine/Amphetamines amphetamine (Benzedrine) bath salts/khat/cathinone benzphetamine (Didrex) dextroamphetamine (Dexedrine) methamphetamine (Desoxyn) methylphenidate (Ritalin) pemoline (Cylert) phenmetrazine (Preludin)	Euphoria, grandiosity, mood swings, hyperactivity, hyperalertness, restlessness, anorexia, insomnia, hypertension, tachycardia, marked vasoconstriction, tremor, dysrhythmias, seizures, sexual arousal, dilated pupils, diaphoresis	Agitation; increased temperature, pulse, respiratory rate, blood pressure; cardiac dysrhythmias; myocardial infarction; hallucinations; seizures; possible death	Severe craving, severely depressed mood, exhaustion, prolonged sleep, apathy, irritability, disorientation
Caffeine	Mood elevation, increased alertness, nervousness, jitteriness, irritability, insomnia, increased respirations, increased heart rate and force of myocardial contraction, relaxation of smooth muscle, diuresis	Rare: Nervousness, confusion, psychomotor agitation, anxiety, dizziness, tinnitus, muscle twitching, elevated blood pressure, tachycardia, extrasystole, increased respiratory rate	Headache, irritability, drowsiness, fatigue
Depressants			
Alcohol ***Sedative Hypnotics*** *Barbiturates* secobarbital (Seconal) pentobarbital (Nembutal) amobarbital (Amytal) *Benzodiazepines* diazepam (Valium) chlordiazepoxide (Librium) alprazolam (Xanax) *Nonbarbiturates/ Nonbenzodiazepines* methaqualone (Quaalude) chloral hydrate (Noctec)	Initial relaxation, emotional lability, decreased inhibitions, drowsiness, lack of coordination, impaired judgment, slurred speech, hypotension, bradycardia, bradypnea, constricted pupils	Shallow respirations; cold, clammy skin; weak, rapid pulse; hyporeflexia; coma; possible death	Anxiety, agitation, insomnia, diaphoresis, tremors, delirium, seizures, possible death
Opioids heroin morphine opium codeine fentanyl (Sublimaze) meperidine (Demerol) hydromorphone (Dilaudid) oxycodone (OxyContin, Percocet) methadone (Dolophine)	Analgesia, euphoria, drowsiness, detachment from environment, relaxation, constricted pupils, constipation, nausea, decreased respiratory rate, slurred speech, impaired judgment, decreased sexual and aggressive drives	Slow, shallow respirations; clammy skin; constricted pupils; coma; possible death	Watery eyes, dilated pupils, runny nose, yawning, tremors, pain, chills, fever, diaphoresis, nausea, vomiting, diarrhea, abdominal cramps

Continued

TABLE 5-2 EFFECTS OF FREQUENTLY ABUSED DRUGS—cont'd

SUBSTANCE	PHYSIOLOGIC AND PSYCHOLOGICAL EFFECTS	TOXICITY	WITHDRAWAL SYNDROME
Cannabis			
Marijuana ***Hashish*** ***Synthetic Marijuana***	Relaxation, euphoria, amotivation, slowed time sensation, sexual arousal, abrupt mood changes, impaired memory and attention, impaired judgment, reddened eyes, dry mouth, lack of coordination, tachycardia, increased appetite	Fatigue, paranoia, panic reactions, hallucinogen-like psychotic states	With heavy use: insomnia, restlessness, irritability, tremor, weight loss, hyperthermia, chills
Psychedelics lysergic acid diethylamide (LSD) psilocybin (mushrooms) dimethyltryptamine (DMT) diethyltryptamine (DET) 3,4-methylendioxyamphetamine (MDMA, Ecstasy) herbal ecstasy (contains herbs and ephedrine) mescaline (peyote) phencyclidine (PCP)	Perceptual distortions, hallucinations, delusions (PCP), depersonalization, heightened sensory perception, euphoria, mood swings, suspiciousness, panic, impaired judgment, increased body temperature, hypertension, flushed face, tremor, dilated pupils, constricted pupils (PCP), nystagmus (PCP), violence (PCP)	Prolonged effects and episodes, anxiety, panic, confusion, blurred vision, increases in blood pressure and temperature	No physical withdrawal, but psychological desire may occur
Inhalants			
Aerosol Propellants fluorinated hydrocarbons nitrous oxide (in deodorants, hair spray, pesticide, whipped cream spray, spray paint, cookware coating products) ***Solvents*** gasoline, kerosene, nail polish remover, typewriter correction fluid, cleaning solutions, lighter fluid, paint, paint thinner, glue ***Anesthetic Agents*** nitrous oxide, chloroform ***Nitrites*** amyl nitrite, butyl nitrite	Euphoria; decreased inhibitions; giddiness; slurred speech; illusions; drowsiness; clouded sensorium; tinnitus; nystagmus; dysrhythmias; cough; nausea; vomiting; diarrhea; irritation to eyes, nose, and mouth	Anxiety, respiratory depression, cardiac dysrhythmias, loss of consciousness, sudden death	None

abuse and its effects can be found in the discussion of lower respiratory disorders in Chapter 41.

Cocaine

Cocaine is a naturally occurring potent stimulant, an alkaloid that was originally obtained from the leaves of the coca plant but today can be prepared synthetically. Historically, cocaine was used as a local anesthetic, but it has been largely replaced by synthetic agents with no abuse potential. Cocaine is a Schedule II drug under the Controlled Substances Act. Illicit cocaine is available as white powder (cocaine hydrochloride) and as cocaine base (alkaloidal cocaine, freebase), a crystalline substance. "Crack," a cocaine base that gets its name from the popping sound the crystals make when heated, is popular because it is less expensive, readily available, and easy to use, and has increased purity over cocaine hydrochloride.

Pharmacokinetics Absorption rates of cocaine depend on the route of administration. Cocaine hydrochloride is usually "snorted" intranasally. Cocaine can also be smoked as crack cocaine or in "freebase" form, injected intravenously (IV), taken orally, or absorbed through the mucous membranes. Smoking and IV methods result in the fastest absorption and the highest "rush." Peak blood levels develop within 5 to 30 minutes with most methods of administration. The longest effects occur following intranasal use because absorption is delayed by vasoconstriction of the nasal vessels. Cocaine is rapidly metabolized by the liver. Elimination half-lives by oral, intranasal, and IV routes are 50, 80, and 60 minutes, respectively. Tolerance appears to occur with long-term use, but users can also become more sensitive to

TABLE 5-3 NICOTINE-REPLACEMENT AGENTS

GENERAL CONSIDERATIONS FOR NICOTINE REPLACEMENT THERAPY (NRT)

NRT should not be used by pregnant or nursing patients.
Smoking while using NRT may cause nicotine overdose.
Tapering of all agents except transdermal patches is required.
Replacement agents used are usually a matter of personal preference.
The stronger doses of agents should be used by heavy smokers.
Using more than one agent at the same time should be discussed with the health care provider.
Generic preparations are available for some agents.

AGENTS	ABSORPTION	SIDE EFFECTS	CONSIDERATIONS
Gum (OTC)			
Nicorette 2 mg, 4 mg	Buccal mucosa	Hiccups, mouth ulcers, indigestion, jaw pain	Specific 30-minute chewing regimen with periods of holding the gum between cheek and teeth; food and drink should be avoided 15 minutes before or during use.
Lozenge (OTC)			
Commit 2 mg, 4 mg	Buccal mucosa	Nausea and indigestion, hiccups, headache, cough, mouth soreness, flatulence	Dissolves in the mouth in 20 to 30 minutes; chewing and swallowing the lozenge increases GI side effects.
Patch (OTC)			
NicoDerm CQ Nicotine transdermal system 18-hour, 24-hour doses	Skin	Skin rash at patch site, headache, dizziness, weakness, indigestion, diarrhea, sleep disturbances with 24-hour patch	Differs from other agents in that it helps prevent craving; cannot be used by those with adhesive allergies.
Nasal Spray			
Nicotrol NS	Nasal mucosa	Nose and throat irritation, sneezing, rhinitis, watery eyes, cough	Requires a prescription; nasal irritation may limit use; affects airways and not a good choice for those with asthma, allergies, or sinus problems.
Inhaler			
Nicotrol nicotine inhalation system, delivers 4 mg	Oral mucosa	Cough; nose, mouth, and throat irritation; heartburn and nausea	Requires a prescription; simulates smoking with mouthpiece and nicotine cartridge; may not be advisable for those with asthma or pulmonary disease.

GI, Gastrointestinal; *OTC,* over-the-counter.

the drug's anesthetic and convulsant effects. Cocaine readily crosses the placenta in pregnant patients and accumulates in the fetal circulation. Conflicting research exists about the effect of prenatal cocaine exposure on the development of the child.

Pharmacodynamics Cocaine inhibits the neuronal uptake of dopamine in the brain and increases the activation of dopamine receptors in the brain reward system. This action magnifies pleasures and leads to rapid dependence. Cocaine also increases norepinephrine at postsynaptic receptor sites, producing intense vasoconstriction and cardiovascular stimulation. Drug interactions with cocaine are identified in Table 5-4.

Side Effects and Adverse Reactions

At usual doses, cocaine produces euphoria and increased energy and alertness. In addition to CNS stimulation, effects include peripheral adrenaline-like actions (see Table 5-2). Chronic use may lead to impairment of concentration and memory, irritability and mood swings, paranoia, and depression.

A stimulant psychosis may occur with the chronic use of any stimulant. A cocaine psychosis usually progresses from paranoid delusions to visual hallucinations of "snow lights" (colored lights when cocaine is administered) and tactile hallucinations of bugs crawling under the skin. Skin excoriations from scratching; needle marks; and elevated blood pressure, heart rate, and temperature are findings that help differentiate a stimulant psychosis from schizophrenia.

Acute cocaine toxicity may be manifested by cardiac palpitations, tachycardia, increased respiratory rate, and fever. At high levels of overdose, grand mal seizures, hypertension, and dysrhythmias or myocardial ischemia can occur. The patient experiences restlessness, paranoia, agitated delirium, and confusion. Bizarre, erratic, and violent behavior may occur. Death is often related to a cerebrovascular accident, fatal dysrhythmias, or myocardial infarction.

The degree of physical dependence produced by cocaine appears to vary among individuals. Some users report little or no evidence of physical withdrawal with abstinence, but others report symptoms similar to those associated with amphetamine withdrawal: dysphoria, fatigue, depression, and a need to sleep. In the first 9 hours to 14 days of abstinence, many users experience an intense psychological response

TABLE 5-4 DRUG INTERACTIONS: DRUGS OF ABUSE

DRUG OF ABUSE	INTERACTING DRUGS/DRUG CATEGORIES	EFFECTS
Nicotine/Smoking*	isoproterenol (Isuprel) phenylephrine (Neo-Synephrine)	Increased effects with use of nicotine/smoking (After smoking cessation, dosages may need to be increased.)
	pentazocine (Talwin NX) propoxyphene (Darvon) Benzodiazepines (diazepam [Valium]) Tricyclic antidepressants propranolol (Inderal) theophylline (Theo-Dur, others) heparin insulin	Decreased effects with use of nicotine/smoking (After smoking cessation, dosages may need to be reduced.)
Cocaine	Sympathomimetics/adrenomimetics Central nervous system (CNS) stimulants Cholinesterase inhibitors (neostigmine)	May increase CNS and cardiac effects of cocaine
	Tricyclic antidepressants, digoxin, methyldopa (Aldomet)	May increase cocaine-induced dysrhythmias
	Beta-adrenergic blockers	Cocaine may decrease effects
Amphetamines	Tricyclic antidepressants Sympathomimetics/adrenomimetics CNS stimulants	Increased effect of tricyclic antidepressants and sympathomimetics; increased effect of amphetamines
	GI antacids/urinary alkalinizing agents Monoamine oxidase inhibitors (MAOIs)	Increased effect of amphetamine
	meperidine (Demerol)	Amphetamines increase analgesic effect; meperidine increases risk of seizures and vascular collapse.
	Thyroid hormone	Reciprocal increase in effects
	Adrenergic blockers Antihistamines Antihypertensives	Amphetamines may decrease effects.
Alcohol	Other CNS depressants: Sedative-hypnotics Opioids General anesthetics	Increased CNS depression with increased risk of death from respiratory depression
	Nonsteroidal antiinflammatory drugs	Combined effect increases risk of gastric bleeding
	acetaminophen (Tylenol)	Increased risk for liver injury
	Antihypertensives	Decreased effect of antihypertensives
Barbiturates	Other CNS depressants: Alcohol Opioids General anesthetics Other sedative/hypnotics MAOIs valproic acid (Depakene)	Increased CNS depression
	Oral anticoagulants Corticosteroids and other steroid hormones griseofulvin (Fluvicin) doxycycline	Effect decreased by barbiturates
Benzodiazepines	Other CNS depressants: Alcohol Opioids General anesthetics Other sedative/hypnotics Herbs: Kava kava, valerian	Increased CNS depression

TABLE 5-4 DRUG INTERACTIONS: DRUGS OF ABUSE—cont'd

DRUG OF ABUSE	INTERACTING DRUGS/DRUG CATEGORIES	EFFECTS
Opioids	Other CNS depressants: Alcohol General anesthetics Sedative/hypnotics Phenothiazines Antiemetics	Increased CNS depression
	Mixed agonist/antagonist opioids	Reduces the effect of pure opioid agonists and may precipitate withdrawal syndrome
	MAOIs	May cause severe fatal reaction
	Diuretics	Opioids may decrease effect
Marijuana/Hashish	CNS stimulants/sympathomimetics Anticholinergic agents Tricyclic antidepressants	Additive hypertension, tachycardia, drowsiness
	CNS depressants	Additive drowsiness and CNS depression
	theophylline	Decreased effect of theophylline

CNS, Central nervous system; *GI,* gastrointestinal; *MAOIs,* monoamine oxidase inhibitors.
*Interactions may be due to nicotine or the effect on the liver by hydrocarbons found in cigarette smoke.

characterized by intense craving and cocaine-seeking behavior (see Table 5-2). Eventually, mood becomes more normal, but a desire to return to the drug, especially prompted by cue-induced craving, remains for an indefinite period. In rare instances, withdrawal can be prolonged and difficult.

Treatment

Emergency management of cocaine toxicity depends on the patient findings at the time of treatment. Treatment may be complicated by the possibility that the patient has combined the use of cocaine with heroin, alcohol, or PCP. There is no specific antidote for cocaine toxicity, but during an overdose most symptoms can be controlled with a variety of drugs. Emergency interventions for assessment findings in cocaine toxicity are presented in Table 5-5.

Cognitive-behavioral therapies are often the only effective approach to cocaine addiction, but maintenance of cocaine abstinence with behavioral therapies has been difficult to achieve in most users. No drugs are currently approved to promote cocaine abstinence; however, disulfiram (Antabuse), a well-established medication for treatment of alcoholism, has helped nonalcoholic people addicted to cocaine reduce drug use from 2.5 days per week to 0.5 days per week on average. It has also been found that when modafinil (Provigil), a CNS stimulant used for treatment of narcolepsy, is combined with behavioral therapy, the likelihood of cocaine abstinence increases. The anticonvulsant topiramate (Topamax) and the antiemetic ondansetron (Zofran) have shown some efficacy for treating cocaine addiction and may benefit some individuals, but they are not approved for this use by the FDA. Additionally, research shows promise for a vaccine that works by stimulating the production of

TABLE 5-5 DRUG THERAPY FOR COCAINE AND AMPHETAMINE TOXICITY

ASSESSMENT FINDINGS	DRUG THERAPY
Cardiovascular	
Palpitations Tachycardia Hypertension Dysrhythmias Myocardial ischemia or infarction	Establish IV access, and initiate fluid replacement as appropriate. Anticipate the need for propranolol (Inderal) or labetalol (Normodyne) for hypertension and tachycardia. Severe hypertension may require administration of nitroprusside (Nipride) or phentolamine (Regitine). Treat ventricular dysrhythmias as appropriate with lidocaine, bretylium (Bretylol), or procainamide (Pronestyl). Aspirin may be administered to lower the risk of myocardial infarction.
Central Nervous System (CNS)	
Feeling of impending doom Euphoria Agitation Combativeness Seizures Hallucinations Confusion Paranoia Fever	Naloxone (Narcan) IV should be given if CNS depression is present and concurrent opiate use is suspected. Administer diazepam (Valium) or lorazepam (Ativan) IV for agitation and seizures. Administer chlorpromazine (Thorazine) or haloperidol (Haldol) IV for psychosis and hallucinations.

IV, intravenous.

cocaine-specific antibodies that bind to cocaine molecules, rendering them ineffective.

Amphetamines

Amphetamine is a synthetic drug and, with its derivatives and similar stimulants, is strictly regulated today as a Schedule II drug of the Controlled Substances Act. Specific drugs classified as amphetamines are identified in Table 5-2 and Chapter 20. Because amphetamines may be used therapeutically as CNS stimulants, abuse may rise out of slow escalation of a prescribed dose. However, they are more often initially used a cheaper alternative to cocaine.

Methamphetamine (crank) and methamphetamine crystals (crystal meth) are very potent stimulants and can be easily made in clandestine settings with relatively inexpensive over-the-counter (OTC) ingredients. Methamphetamine abuse is a growing problem in all segments of the population and geographic regions.

Pharmacokinetics Amphetamines are prescribed for oral use, with peak effects occurring within 60 to 90 minutes and lasting 2 to 4 hours. More rapid effects are obtained by smoking, snorting, or IV injection; and they are therefore more frequently used illicitly in these manners. Amphetamines have a longer half-life than cocaine and a longer, more intense effect. Additional information regarding the pharmacodynamics and pharmacokinetics of amphetamines can be found in Chapter 20.

Pharmacodynamics Amphetamines act similarly to cocaine, stimulating the release of dopamine and norepinephrine in the brain and the sympathetic nervous system. The dopamine release in the brain reward system produces euphoria and an increase in self-confidence. Drug interactions with amphetamines are identified in Table 5-4.

Side Effects and Adverse Reactions

Initial use of amphetamines results in increased alertness, improved performance, relief of fatigue, and anorexia. Stimulation of the sympathetic nervous system leads to cardiovascular stimulation with increased heart rate and blood pressure. Amphetamine use over time can lead to irritability, anxiety, paranoia, and hostile and violent behaviors. The physical effects of extended methamphetamine abuse are notable in tooth decay and dermatologic deterioration (Figure 5-1).

Toxic reactions to amphetamines are similar to those to cocaine. Increased levels of stimulation, sometimes described as "overamping," may result in amphetamine psychosis, paranoia, seizures, and death (see Table 5-2). Without medical intervention, death may occur as a result of dysrhythmias, myocardial infarction, hyperthermia, and cerebral hemorrhage.

Withdrawal symptoms of amphetamine use are similar to those of cocaine use and are presented in Table 5-2. Amphetamines usually cause only mild physical dependence, but craving can be intense during abstinence. IV use will cause the onset of withdrawal symptoms in approximately 2 hours, whereas oral use results in withdrawal symptoms in 8 to 10 hours.

"Bath salts" is the name for a group of synthetic stimulants that mimic many effects of amphetamines. These drugs contain synthetic versions of cathinone, a compound found in the khat plant that causes amphetamine-like stimulant

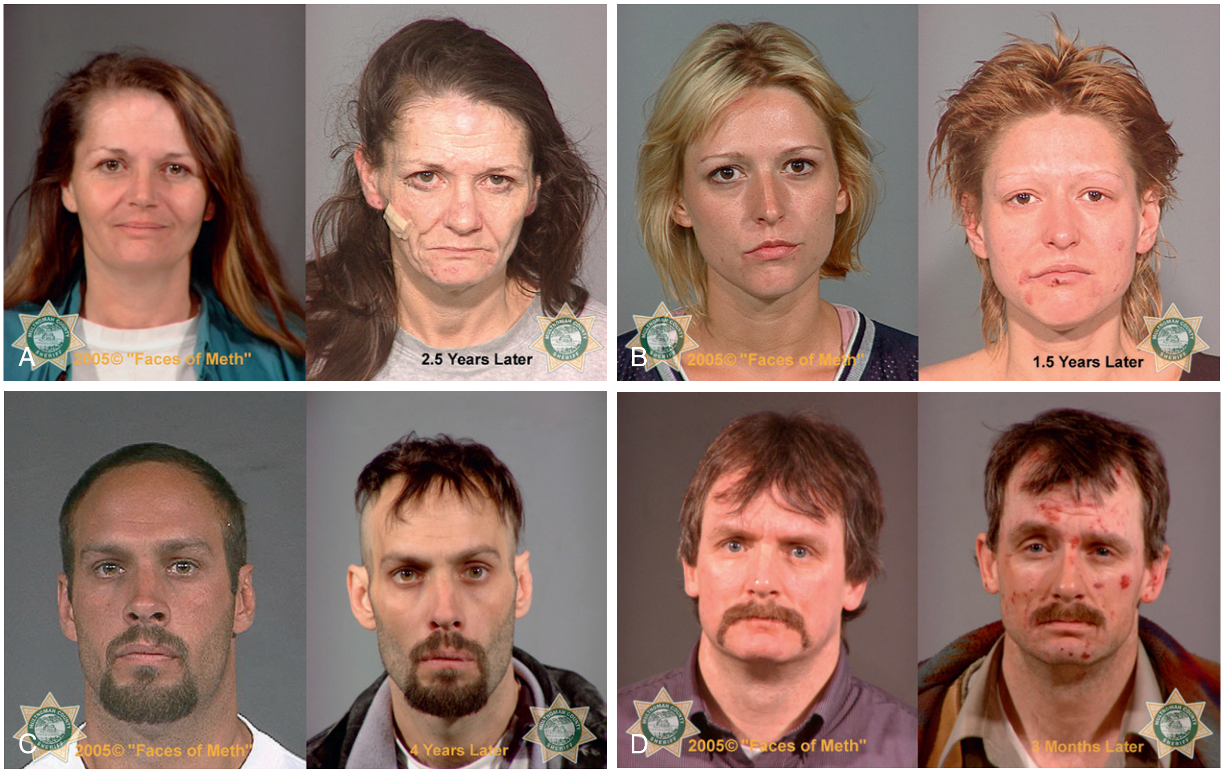

FIGURE 5–1 Methamphetamine abuse can cause significant physical deterioration. (Copyright 2014 by Faces of Meth™. Used with permission.)

effects. These are not for use in bathing; the name "bath salts" has been used to evade authorities and sell the intoxicant in retail settings. It has also been sold as jewelry cleaner or plant food, often labeled "Not for human consumption," with brand names like "White Lightning," "Cloud Nine," or "Vanilla Sky." Negative effects of these drugs are tachycardia; hypertension; psychiatric symptoms of hallucinations, paranoia, and panic attacks; kidney failure; and death.

Treatment

Patients often seek treatment for complications of amphetamine abuse such as panic reactions, psychosis, or depression. Emergency management of amphetamine toxicity is the same as that for cocaine. Elevated blood pressure and tachycardia can be controlled with vasodilators and beta-adrenergic blockers. Drug elimination can be enhanced by administering agents such as ammonium chloride that acidify the urine. Emergency treatment of amphetamine toxicity is shown in Table 5-5.

Cessation and maintenance of abstinence are difficult in amphetamine abuse. Like cocaine, withdrawal causes more psychological symptoms than physical symptoms. Depression can last for months and is a common cause of relapse. No specific drug therapy is indicated to help maintain abstinence. It is possible that agents being tested to promote cocaine abstinence may also be effective for amphetamine abuse.

Caffeine

Caffeine is the most widely used psychoactive substance in the world. Its use to promote alertness and to alleviate fatigue is safe in most people. However, of concern to health professionals is the marketing of caffeine-laden "energy" drinks directed specifically to teenagers and young adults. Used by about 30% of 18- to 24-year-olds in the United States, these products provide a "buzz" to fight fatigue, brighten mood, and increase physical and mental performance. Caffeine is also added to some brands of alcoholic drinks, and energy drinks may be used as mixers with alcohol.

Caffeine combined with alcohol appears to improve response time but does not reduce the errors in judgment caused by alcohol. Although weaker than other stimulant drugs, caffeine shares characteristics of intoxication, tolerance, and withdrawal symptoms in some individuals, especially when high doses are used.

Pharmacokinetics Caffeine is readily absorbed from the GI tract and reaches peak plasma levels in about 1 hour. Additional information regarding the pharmacodynamics and pharmacokinetics of caffeine is presented in Chapter 20.

Pharmacodynamics Caffeine is a methylxanthine that stimulates the CNS, especially the medullary respiratory center. It also is a diuretic and myocardial stimulant. It can worsen peripheral vasoconstriction in those with hypertension and causes cerebral vasodilation, making it an effective treatment for migraines and headaches.

Side Effects and Adverse Reactions

Oral doses of 200 mg of caffeine (two cups of coffee) can elevate mood and offset fatigue, but can also produce insomnia, increase irritability, and cause anxiety. Intake of 500 mg or more per day is known to cause intoxication with symptoms of nervousness, insomnia, gastric hyperacidity, muscle twitching, confusion, chest pain, tachycardia, and cardiac dysrhythmias. In toxic doses, caffeine influences behavior patterns and may precipitate states of panic. Until the advent of caffeine pills and highly caffeinated energy drinks, caffeine overdoses were very rare because people developed undesirable symptoms before they could ingest enough. Now toxicity can result from several cans of energy drinks or from caffeine supplements. Also of concern is caffeine toxicity in young children, who may show symptoms with much smaller doses. Although the government does not require food and drink manufacturers to list caffeine content, public concern about children's access to energy drinks has induced soft drink manufacturers to start labeling caffeine content on drinks.

Physical and psychological dependence on caffeine have been found with chronic use of more than 500 mg/day. However, dependence may occur in some individuals at lower doses. The most commonly reported withdrawal symptoms are headache, irritability, drowsiness, and fatigue occurring within 12 to 24 hours after abstinence. Caffeine withdrawal may be responsible for some cases of headache that occur after general anesthesia. It is thought that weekend headaches may also be related to caffeine withdrawal, because caffeine consumption may be different during the workweek than on the weekend. Effects of caffeine are shown in Table 5-2.

Treatment

Toxic reactions to caffeine and lethal doses of caffeine are managed symptomatically. Attention is given to controlling hypertension, dysrhythmias, and seizures, as with other CNS stimulants. Management of the patient with symptoms of caffeine dependence includes assisting the patient to reduce or stop caffeine intake gradually. Supplying a list of caffeinated products with their dosages may help the patient avoid caffeine intake. Substituting decaffeinated beverages may also help (decaffeinated coffee and tea contain 2 to 4 mg of caffeine per cup).

DEPRESSANTS

Drugs classified as depressants have common physiologic and psychological effects of sedation, decreased respiratory and cardiac rates, and depressed CNS function. Drugs in this category include alcohol, sedative-hypnotics, anxiolytics, and opioid narcotics. With the exception of alcohol and some federally regulated drugs, most CNS depressants are medically useful. These drugs are also widely recognized for their abuse potential, which leads to rapid tolerance, dependence, and medical emergencies involving overdose and withdrawal.

Alcohol

Alcohol is the most widely consumed substance of abuse in the United States. Most people use alcohol in moderation, with some positive cardiovascular and cognitive benefits. Abuse of alcohol, however, can lead to dependence and significant health, social, legal, and interpersonal problems. Alcoholism (alcohol dependency) is a chronic, progressive, potentially fatal disease if left untreated.

Pharmacokinetics Alcohol is absorbed directly from the stomach and small intestine. Absorption from the stomach is slower in the presence of water or food, especially proteins and fats. Faster absorption occurs when alcohol is mixed with carbonated liquids. Alcohol is distributed to all body tissues and fluids. It crosses the placenta and can affect fetal development. Alcohol is primarily metabolized in the liver, although a small amount is metabolized in the stomach. Unlike most other drugs in which the metabolic rate increases as plasma drug levels rise, alcohol is usually metabolized at a relatively constant rate. In an occasional or moderate drinker, that metabolic rate is approximately one drink (7 g of alcohol) per hour. One drink is equal to 12 ounces of beer, 5 ounces of wine, or 1 ounce of distilled spirits. However, regular or heavy use of alcohol increases the rate of liver metabolism of alcohol and other drugs. Because women have significantly lower rates of alcohol metabolism, they have higher blood alcohol levels than men after ingesting the same amount of alcohol.

Pharmacodynamics Alcohol affects almost all cells of the body and has complex effects on the neurons in the CNS. Alcohol is a general CNS depressant. Additionally, alcohol binds with receptors in the brain reward system, resulting in the release of dopamine and promoting the addictive process.

The concentration of alcohol in the body can be determined by assessing the blood alcohol concentration (BAC). For the nondependent drinker, the BAC is fairly predictable of alcohol's effects (Table 5-6). The relationship between BAC and behavior is different in a person who has developed tolerance to alcohol and its effects. This individual is commonly able to drink large amounts without obvious impairment at BAC levels several times higher than those that would produce obvious impairment in the nontolerant drinker. However, little tolerance develops to respiratory depression. Chronic heavy alcohol users reach the lethal BAC at almost the same level as nonusers.

Alcohol interacts with many commonly prescribed or OTC medications (see Table 5-4). **Potentiation** and cross-tolerance with other CNS depressants also may occur. Potentiation occurs when an additional CNS depressant is taken with alcohol, increasing the effect. **Cross-tolerance**, the need for an increased dose of other drugs, also develops to general anesthetics, barbiturates, and other general CNS depressants. No cross-tolerance develops to opioids.

Side Effects and Adverse Reactions

Alcohol intoxication is evidenced with an increasing BAC and results in behavioral and physical changes (see Tables 5-2 and 5-6). Acute overdose produces vomiting, coma, and respiratory depression. Alcohol-induced hypotension may lead to renal failure and cardiogenic shock, common causes of alcohol-related death.

The effects of chronic alcohol use are numerous. One condition that can be prevented is **Wernicke's encephalopathy**, an inflammatory, hemorrhagic, degenerative condition of the brain resulting from a deficiency of thiamine owing to malnutrition associated with chronic alcohol use. Untreated or progressive Wernicke's encephalopathy may lead to **Korsakoff's psychosis**, a form of amnesia characterized by loss of short-term memory and an inability to learn.

After excessive drinking, nondependent individuals experience malaise, nausea, headache, thirst, and a general feeling of fatigue. In those with an alcohol addiction, sudden withdrawal from alcohol may have life-threatening effects. Withdrawal syndrome should be anticipated if the patient reports consumption of more than 10 drinks every day for a period of 2 weeks. Characteristic signs of withdrawal are gross tremors, seizures, hallucinations, and alcohol withdrawal delirium; they develop because the brain has adapted to the consistent presence of alcohol, a depressant. The brain is accustomed to functioning in the presence of a substance inhibiting its activity; thus, symptoms of withdrawal develop when alcohol is removed.

TABLE 5-6 BLOOD ALCOHOL CONCENTRATION AND RELATED EFFECTS

BAC* (MG%)	PHYSICAL AND PSYCHOLOGICAL EFFECTS
20 (0.02)	Light and moderate drinkers begin to feel some effects after one drink.
40 (0.04)	Most people begin to feel relaxed.
60 (0.06)	Judgment is mildly impaired. People are less able to make rational decisions about their capabilities (e.g., driving skills).
80 (0.08)	Definite impairment of muscle coordination and driving skills occurs. Person is legally intoxicated in some states.
100 (0.10)	Clear deterioration of reaction time and control is observed. Person is legally intoxicated in most states.
120 (0.12)	Vomiting occurs unless this level is reached slowly.
150 (0.15)	Balance and movement are impaired. Equivalent of one half pint of whiskey is circulating in the bloodstream.
300 (0.30)	Many people lose consciousness.
400 (0.40)	Most people lose consciousness, and some die.
450 (0.45)	Breathing stops; person eventually dies.

*Blood alcohol concentration (BAC) is generally recorded in milligrams of alcohol per deciliter (mg/dL) of blood or milligrams percent (mg%). Percentage is used for legal definitions of intoxication. BAC is dependent on how much alcohol is consumed, how fast it is consumed, and the individual's weight.

The onset of withdrawal symptoms is variable, depending on the person's drinking pattern. Symptoms (see Table 5-2) may occur the first 4 to 6 hours after the last drink, peak at 24 to 36 hours, and last up to 5 days. Anticipation of withdrawal syndrome should always include assessment of the time of the last alcohol intake. Seizures are most likely to occur 7 to 48 hours after the last drink. Alcohol withdrawal delirium is a serious complication that may occur from 30 to 120 hours after the last drink. Delirium components include disorientation, visual or auditory hallucinations, and increased hyperactivity without seizures. Death may be caused by hyperthermia, peripheral vascular collapse, or cardiac failure.

Treatment

Initial treatment of acute alcohol intoxication or overdose requires implementation of the basic principles of airway, breathing, and circulation (ABCs). No antidote for alcohol is available, and stimulants should not be given. Alcohol-induced hypotension cannot be corrected with vasoconstrictors. Alcohol may be removed from the body by gastric lavage and dialysis. Because symptoms of Wernicke's encephalopathy may be difficult to distinguish from those of intoxication, and because Wernicke's encephalopathy is potentially reversible, IV thiamine at a dose of 100 mg/day is often administered to intoxicated patients. Patients with alcohol intoxication may also be hypoglycemic because of lack of food intake. Treatment with IV glucose solutions may precipitate Wernicke's encephalopathy in a previously unaffected patient. For this reason, thiamine should be started before treatment with IV glucose solution in all patients with alcoholism and continued until the patient resumes regular eating.

Although specific drugs are not indicated for acute alcohol toxicity, drugs are available to facilitate alcohol withdrawal and help maintain abstinence. Management of alcohol withdrawal frequently includes the use of a variety of drugs. Anticipating withdrawal syndrome in patients is important because alcohol withdrawal delirium can usually be prevented by administration of benzodiazepines such as chlordiazepoxide (Librium) or lorazepam (Ativan) if the patient has liver dysfunction. Benzodiazepines with long half-lives are the most effective drugs in alcohol withdrawal to stabilize vital signs, reduce symptoms, and decrease the risk of seizures and delirium. Benzodiazepines are discussed further in Chapter 21. Additional drugs used as adjuncts to benzodiazepines are included in Table 5-7.

Rehabilitation and sustained abstinence are the primary long-term goals of alcohol treatment. Drugs approved to maintain abstinence may be used in addition to cognitive-behavioral therapy for long-term treatment. These include disulfiram (Antabuse), which prevents drinking by causing an unpleasant reaction if alcohol is consumed, and naltrexone, which blocks the desired effects of alcohol. Disulfiram disrupts alcohol metabolism, causing accumulation of acetaldehyde when alcohol is ingested. An adverse reaction to the accumulated acetaldehyde begins with flushing in the face and develops into intense vasodilation of the face, neck, and upper part of the body. Hyperventilation and palpitations may occur. Nausea occurs in 30 to 60 minutes with copious vomiting. Headache, sweating, thirst, chest pain, weakness, blurred vision, and hypotension follow. Blood pressure may decline to shock levels. The reaction lasts from 30 minutes to several hours and can be brought on by ingesting as little as 7 mL of alcohol. In its most severe form, it can be life threatening. In the absence of alcohol, disulfiram may cause drowsiness and skin eruptions that diminish over time. Disulfiram is metabolized by the liver, and excretion of metabolites occurs through the kidneys and lungs. Up to 20% of the drug is excreted unchanged in the feces. Effects may persist for up to 2 weeks after the last dose is taken. Patient education regarding disulfiram therapy is extremely important. Patients must be made aware that consumption of any alcohol, even use of alcohol-based mouthwash, while taking disulfiram can cause a severe, potentially fatal reaction. All food and liquid medication labels must be checked for the presence of alcohol, and alcohol must not be used on the skin. Because disulfiram is self-administered, patients must be highly motivated to abstain from alcohol for it to be effective. Additionally, using a family or other strong support system improves adherence to daily dosing of disulfiram.

TABLE 5-7 DRUG THERAPY FOR ALCOHOL WITHDRAWAL

CLINICAL MANIFESTATIONS	MEDICATIONS
Minor Withdrawal Syndrome	
Tremulousness, anxiety Insomnia Increased heart rate Increased blood pressure Sweating Nausea Hyperreflexia	Long-acting benzodiazepines (e.g., lorazepam [Ativan], chlordiazepoxide [Librium]) to stabilize vital signs, reduce anxiety, and prevent seizures and delirium Thiamine to prevent Wernicke's encephalopathy Multivitamins (folic acid, B vitamins) for nutritional support Magnesium sulfate if serum magnesium is low Glucose solutions IV if hypoglycemia is present (after thiamine)
Major Withdrawal Syndrome	
Disorientation Visual/auditory hallucinations Increased hyperactivity without seizures Gross tremors Seizures Alcohol withdrawal delirium	Continue use of benzodiazepines and add: Antipsychotic drugs (e.g., haloperidol [Haldol]) for hallucinations and delirium Carbamazepine (Tegretol) or phenytoin (Dilantin) to prevent or treat seizures

IV, Intravenous.

HERBAL ALERT 5-1

St. John's Wort

St. John's wort, if taken with disulfiram (Antabuse), may cause a reaction similar to alcohol.

Naltrexone is a pure opioid antagonist that decreases craving for alcohol and blocks the "high" of alcohol use. It was originally approved for treatment of opioid addiction but was also approved for alcohol dependency when clinical trials found that it reduced alcohol relapse rates by 50% when combined with extensive counseling. Naltrexone (ReVia, Depade) 50 mg once a day by mouth is the usual dose for alcohol dependency. Naltrexone is also available in an injectable extended-release form (Vivitrol) that is given intramuscularly once a month. This drug is indicated for alcohol-dependent patients who are able to abstain from drinking in an outpatient setting and are not actively drinking when starting treatment. Naltrexone is discussed further with opioid abuse later in this chapter and in Chapter 26.

Acamprosate (Campral) is used to decrease unpleasant feelings such as tension, dysphoria, anxiety, and cravings brought about by abstinence from alcohol. It is thought to act on the brain pathways related to alcohol abuse. Dosing should start immediately after detoxification and continue even if relapse occurs. Acamprosate is not addicting but is somewhat less effective than naltrexone. Combining acamprosate with naltrexone is more effective than acamprosate alone but no better than naltrexone alone. The most common adverse effects reported include headache, diarrhea, flatulence, and nausea.

Two marketed drugs are currently being studied for their use in long-term alcohol abstinence. Ondansetron (Zofran), an antagonist of receptors in the brain reward system, decreases motivation for drinking in early onset alcoholism; and topiramate (Topamax), an anticonvulsant, may be helpful in decreasing craving for alcohol as well as cocaine.

Sedative-Hypnotics

Commonly abused sedative-hypnotic agents include barbiturates, benzodiazepines, and barbiturate-like drugs. Benzodiazepines have largely replaced barbiturates as therapeutic agents for anxiety and insomnia, because they have less risk of toxicity, tolerance, and dependence. The short-acting barbiturates are preferred as recreational drugs because they more frequently produce euphoric effects. Chapter 21 covers the topic of CNS depressants in greater detail.

Pharmacokinetics and Pharmacodynamics Sedative-hypnotic drugs act primarily on the CNS. Benzodiazepines enhance the effects of gamma-aminobutyric acid (GABA), an inhibitory neurotransmitter in the brain. Barbiturates not only enhance the inhibitory effect of GABA, but they can directly mimic the actions of GABA. Barbiturates are powerful respiratory depressants and can readily cause death by overdose. For more on the pharmacodynamics and pharmacokinetics of these drugs, see Chapter 21.

Side Effects and Adverse Reactions

The abuse potential is much greater for barbiturates than benzodiazepines. The drugs are usually taken orally, but both may be injected intravenously. Excessive doses produce an initial euphoria and intoxication similar to that of alcohol. Effects of sedative-hypnotics are presented in Table 5-2.

Tolerance develops rapidly to the sedative effects of barbiturates, requiring higher doses to achieve euphoria. Little tolerance develops to respiratory depression, however, and increasing doses may trigger hypotension and respiratory depression, resulting in death. Cross-tolerance also develops between barbiturates and other CNS depressants such as alcohol, benzodiazepines, and general anesthetics. Little cross-tolerance occurs with opioids, however. In addition, many drug interactions are associated with barbiturates and benzodiazepines (see Table 5-4). An overdose of a sedative-hypnotic produces respiratory depression and coma. Other symptoms of overdose are listed in Table 5-2.

Withdrawal from sedative-hypnotics can be very serious. In the first 12 to 16 hours after the last dose, the patient may develop anxiety, tremors, weakness, nausea, vomiting, muscle cramps, and increased reflexes. After 24 hours, the patient craves the drug and may experience delirium, grand mal seizures, and respiratory and cardiac arrest (see Table 5-2). Symptoms of withdrawal peak on the second or third day for short-acting (shorter half-life) drugs (e.g., alprazolam, secobarbital, pentobarbital) and on the seventh or eighth day for long-acting (longer half-life) drugs (e.g., diazepam, chlordiazepoxide).

Treatment

Overdoses of benzodiazepines are treated with flumazenil (Romazicon), a specific benzodiazepine antagonist. No antagonists are known to counteract the effects of barbiturates or other sedative-hypnotic drugs. Emergency life support measures must be taken in cases of overdose. Gastric lavage may be used in extremely toxic cases if the drug was taken orally within the last hour. Dialysis may be required to decrease the drug level. Gradual withdrawal of the drug is required during withdrawal syndrome. Phenobarbital, a long-acting barbiturate, may be used to control withdrawal symptoms in a patient dependent on barbiturates. Phenobarbital is gradually withdrawn when the patient is stable. To manage symptoms safely, hospitalization is recommended during drug withdrawal for patients who have been abusing large amounts of barbiturates.

Opioids

Opioids include the naturally occurring opiates derived from opium and the many semisynthetic and synthetic narcotic agents used as analgesics. Individuals who abuse opioids include those who use illegal drugs sold on the street and individuals who misuse prescription opioids. Those who begin drug use illegally constitute the largest group of abusers. Street use is usually of heroin. In the medical setting, some people misuse prescribed analgesics, including health care professionals, who may have the highest rate of opioid abuse and dependence of any middle-class population. Ready access to drugs, stresses of the workplace environment, and long hours that interfere with family life are considered contributing factors in health care professionals. Drug abuse and chemical dependency in nurses are discussed later in this chapter.

Pharmacokinetics and Pharmacodynamics Pharmacokinetics and pharmacodynamics of opioids are presented in Chapter 26. Important to the abuse potential of opioids is their ability to activate the brain reward system, reinforcing an addictive effect. As drugs of abuse, opioids are taken orally, sniffed, smoked, or injected subcutaneously ("skin-popping") or intravenously ("mainlining"). IV use will produce effects in seconds. Smoking or sniffing produces a longer onset and effect. Drug interactions with opioids are identified in Table 5-4.

Side Effects and Adverse Reactions

The primary effects of opioids include analgesia, drowsiness, slurred speech, and detachment from the environment. IV use usually causes a "rush" of feelings in the lower abdomen, along with warm skin flushing and a strong sense of euphoria. Opioid use leads to rapid tolerance and physical dependence after short-term use. Cross-tolerance among opioids is common, but cross-tolerance to other CNS depressants does not occur. However, additive effects of other CNS depressants may lead to increased CNS depression.

Signs of overdose of opioids include pinpoint pupils, clammy skin, depressed respiration, coma, and death, if not treated (see Table 5-2). Unintentional overdose frequently occurs with recreational use of the drugs because of the unpredictability in potency and purity. Withdrawal symptoms occur with decreased amounts or cessation of the drug after prolonged moderate to heavy use. The administration of a narcotic antagonist such as naloxone (Narcan) will cause withdrawal symptoms in dependent individuals. Symptoms may include craving, abdominal cramps, diarrhea, nausea, and vomiting (see Table 5-2). Symptoms appear about 8 to 10 hours after the last dose, peak within 36 to 48 hours, and usually subside in 96 hours. Although opioid withdrawal is acutely uncomfortable, it is not usually life threatening.

Treatment

Overdose of opioids can precipitate a medical emergency. A narcotic antagonist such as naloxone should be given as soon as life support is instituted. (The use of naloxone and other narcotic antagonists is discussed in Chapter 26.) Treatment of withdrawal syndrome is symptom-based and does not always require the use of medication. Methadone (Dolophine) in decreasing doses over 10 to 14 days is most often used to decrease symptoms during opioid detoxification. Some patients obtain relief from withdrawal symptoms with the use of clonidine (Catapres), a centrally acting alpha$_2$-adrenergic agonist that may also be used for nicotine addiction (see Chapter 44). It is most effective against GI hyperactivity but does not decrease craving. The action of clonidine in nicotine and opioid addiction is not fully understood.

Long-term management of opioid addiction involves the use of opioid agonists, opioid antagonists, and mixed opioid agonist-antagonists (Table 5-8; see also Chapter 26). Methadone is the most commonly used opioid agonist. By substituting oral methadone for the abused opioid, withdrawal syndrome can be avoided, and the euphoria that leads to craving can be prevented. Methadone is an addictive drug, but its use in maintenance programs alters the drug-using lifestyle, reduces exposure to infectious disease, and controls drug use. To prevent methadone abuse, it is available for addiction treatment only through agencies approved by the FDA and state authorities.

Buprenorphine (Buprenex) is an agonist-antagonist opioid that may be used for detoxification and maintenance therapy. Because of its action on specific opiate receptors, it

TABLE 5-8 DRUGS USED IN OPIOID ADDICTION

STATE WITH SIGNS AND SYMPTOMS	DRUGS
Toxicity Respiratory depression Coma	**Opioid Antagonists** naloxone (Narcan): Short-acting and may need to be repeated until opioid levels decrease; too much will cause withdrawal symptoms. nalmefene (Revex): Long-acting; may cause prolonged withdrawal if dose is excessive
Detoxification/withdrawal Nausea, vomiting, diarrhea Abdominal cramping Bone and muscle pain Muscle spasms Tremor, chills, diaphoresis	**Opioid Substitution** methadone (Dolophine): An opioid agonist that may be used to prevent withdrawal syndrome; when used for withdrawal, it is given in decreasing oral doses over 10 to 14 days after the patient is stabilized. buprenorphine (Subutex): an opioid agonist-antagonist that can be substituted for abused opioids to prevent withdrawal syndrome but can cause withdrawal if an opioid agonist is in the bloodstream; for treatment of withdrawal, it must be given after withdrawal symptoms begin.
	Centrally Acting Alpha$_2$-adrenergic agonist clonidine (Catapres): effective in decreasing GI hyperactivity and some other symptoms of withdrawal; does not reduce craving for the drug.
Maintenance of abstinence Craving, cue-induced craving	**Opioid Agonists** methadone (Dolophine): substitution for abused opioids may be used for long-term treatment of dependency. Addiction is maintained with this method and withdrawal occurs if methadone is stopped, but drug use can be controlled and drug-using lifestyles changed with methadone maintenance.
	Opioid Antagonists naltrexone (ReVia, Depade): blocks opioid receptors, preventing the desired effects if opioids are used; long-acting oral preparation that must be used voluntarily.
	Mixed Opioid Agonist/Antagonists buprenorphine (Subutex), a sublingual tablet, can be used instead of methadone for maintenance therapy. To prevent abuse of buprenorphine itself, it is also marketed in combination with naltrexone as Suboxone. If this preparation is crushed and injected, opioid withdrawal will occur in an opioid-addicted individual. When Suboxone is used sublingually, the opioid agonist effect predominates.

can decrease the symptoms of withdrawal and suppress drug craving, yet it has low potential for abuse. For treatment of withdrawal symptoms, it is available in a sublingual tablet marketed as Subutex. For long-term maintenance, it is combined with naloxone in a sublingual tablet marketed as Suboxone. In this preparation, naloxone is added to the buprenorphine to prevent injection use of the tablets. Because it contains naloxone, Suboxone can produce intense withdrawal symptoms if it is used intravenously. However, the potential for withdrawal is minimal when Suboxone is taken as prescribed because little naloxone is absorbed with sublingual administration in comparison to buprenorphine, which has a significantly higher bioavailability with sublingual administration. Buprenorphine in other forms (e.g., Buprenex) is not approved for treatment of opioid addiction and is used only as a Schedule III analgesic.

SAFETY: Preventing Medication Errors

Do not confuse …

Buprenorphine/naloxone (Suboxone) with

- **Buprenorphine** (Subutex/Buprenex), the same active drug, but without the combination of naloxone
- **Bupropion** (Wellbutrin), an antidepressant
- **Buspirone** (BuSpar), an anxiolytic

Naltrexone (oral ReVia, injectable Vivitrol) is an opioid antagonist that blocks euphoria and all other opioid effects. Like naloxone, it will precipitate withdrawal symptoms when administered to opioid-dependent individuals. When naltrexone is used, administration of an opioid produces no effect, eliminating the reinforcing properties of drug use. It does not prevent craving, however. Naltrexone is used rather than naloxone for maintenance treatment, because it is longer acting and can be taken orally. Usual dosing is orally once a day or alternate days, or intramuscularly once a month.

OTHER DRUGS OF ABUSE

Cannabis

In North America, cannabis is usually sold as marijuana or hashish. Tetrahydrocannabinol (THC) is the active ingredient in cannabis responsible for most of the psychoactive effects. Although a number of potential benefits of THC have been reported, the only approved THC preparation is dronabinol (Marinol), which is used to control nausea and vomiting resulting from cancer chemotherapy. Dronabinol is also used to stimulate appetite in patients with acquired immunodeficiency syndrome (AIDS).

Pharmacokinetics When marijuana is smoked, effects usually occur in 20 to 30 minutes and may last up to 7 hours. Because THC is stored in body fat, it is eliminated slowly, resulting in a half-life of 2 to 7 days. When taken orally, it is almost completely absorbed but undergoes extensive first-pass metabolism.

Pharmacodynamics At low to moderate doses, THC produces fewer physiologic and psychological alterations than do other classes of psychoactive drugs, including alcohol. Although its mechanism of action is uncertain, THC affects cannabinoid receptors in the brain and may act in part through the same reward system as opioids and cocaine.

Side Effects and Adverse Reactions

Marijuana and hashish are usually smoked with the usual effects of euphoria, sedation, and hallucinations. Responses are varied and depend on dose, expectations of the user, and the setting of drug use. Low to moderate doses result in euphoria and relaxation, enhanced sensory perception, and distortion of time perception. Undesirable responses include short-term memory loss, decreased ability to perform multistep tasks, and temporal disintegration. High doses may cause serious psychological effects; intense anxiety, delusions, paranoia, and a state of toxic psychosis can occur. Effects vary among individuals (see Table 5-2). Some individuals experience ill effects only at extremely high doses, while others routinely experience adverse effects at moderate doses. Physiologic effects are seen most commonly in the cardiovascular and respiratory systems. Decreased sperm production, and decreased reproductive hormones in both men and women may occur. Problems of chronic heavy use include decreased motor coordination, tremors, and increased heart and respiratory rates. A condition known as *amotivational syndrome*, characterized by apathy, dullness, and disinterest, may also occur.

Acute reactions, including intoxication and withdrawal, are usually mild and time-limited. Marijuana has low toxicity and no known level of lethal dose. Complications may result when marijuana is used with other drugs, such as heroin and cocaine (see Table 5-4). When taken in extremely high doses, marijuana can produce tolerance and physical dependence. Abrupt cessation of high-dose marijuana may cause irritability, restlessness, nervousness, insomnia, and tremor. In rare instances, withdrawal can be prolonged and difficult.

Synthetic marijuana has been growing in availability. Referred to as “Spice” or “K2,” synthetic marijuana is purported to be a combination of various natural, plant-based, materials; chemical analysis, however, has shown that synthetic cannabinoids are the active ingredient. These products were legal in the United States because none of the identified ingredients were explicitly banned by controlled substances acts; however, many states have moved to make the sale or possession of synthetic marijuana illegal. It is usually smoked and causes intoxication with similar effects to marijuana. It is known to cause nausea, vomiting, hypertension, and myocardial ischemia and has been associated in some cases with myocardial infarction.

Treatment

Individuals using marijuana may seek treatment for anxiety or mood symptoms or may be treated for toxic reactions to a combination of drugs that includes marijuana. Treatment is directed toward relief of symptoms, and administration of drugs is avoided if possible. There is no antidote or substitution therapy for cannabis.

Psychedelic Agents

Psychedelic drugs are often referred to as *hallucinogens.* These drugs produce a change in level of consciousness and induce hallucinations and mental states that resemble psychosis. Primarily, they bring about alterations in thoughts, perceptions, and feelings that normally only occur in dreams. Common agents and their effects are identified in Table 5-2. Although LSD originally was thought to provide a model for the study of psychosis, this idea was found to be incorrect. As a result, the drugs have no recognized medical use. Currently ecstasy (3,4-methylenedioxymethamphetamine or MDMA) is the most commonly used psychedelic. It is popular among adolescents and young adults and may also be abused as a "rape drug."

The effects of psychedelic drug use are primarily psychological, but cardiovascular and neurologic toxicity may occur. Little or no physical dependence develops, but acute panic reactions are common with toxicity. Panic attacks may be treated with an antianxiety agent such as diazepam (Valium) and by providing a nonthreatening environment. Although a toxic reaction may mimic psychosis, the use of antipsychotic agents such as phenothiazines (e.g., haloperidol, chlorpromazine) can intensify rather than ameliorate the experience.

Inhalants

Inhalation is the major route of ingestion for a number of common household and industrial volatile substances. Forms of use include sniffing, huffing, bagging, or spraying. Because inhalants are readily accessible, inexpensive, and produce a rapid high, they are more often used by preadolescents and adolescents.

The four main classes of inhalants are volatile solvents, aerosols, anesthetic agents, and nitrites. They act as CNS depressants but are also extremely damaging to the cardiovascular and respiratory systems. Common agents and their effects are presented in Table 5-2. Users may develop peripheral neuropathies and exhibit tremors and weakness. Sudden death may occur from direct toxic effects, aspiration of gastric contents, trauma, and suffocation. No antidotes are available for these substances, and treatment of toxicity is symptomatic.

Prescription Drugs

The growing popularity of prescription medication abuse is due in part to ease of access as well as to misplaced belief that these drugs always are safe. The types of prescription medications most frequently misused are pain medications and sedative-hypnotics. Individuals may obtain these medications as valid prescriptions for legitimate health issues but use the drug in a nonprescribed manner; others may use someone else's prescription with or without their knowledge or permission. Nurses must be active in addressing this health concern. One way this can be done is by thorough patient education on safe storage and disposal of medications (see Chapter 12).

BOX 5-1 SURGICAL CONSIDERATIONS: PATIENTS WITH DRUG ABUSE

Standard amounts of anesthetic and analgesic medication may not be sufficient because of cross-tolerance.

Anesthetic agents may have a prolonged sedative effect if the patient has liver dysfunction.

Increased doses of pain medication may be required if the patient is dependent on opioids.

Dosage of pain medications must be reduced gradually.

Patients have an increased susceptibility to cardiac and respiratory depression.

Patients have an increased risk for bleeding, postoperative complications, and infection.

Withdrawal symptoms from central nervous system depressants may be delayed for up to 5 days because of effects of anesthetics and pain medications.

SPECIAL NEEDS OF DRUG-ABUSING PATIENTS

Surgical Patients

An individual who abuses drugs is at high risk for drug interactions, complications, and death when surgery is required (Box 5-1). Preoperative assessment of all patients must include an assessment of drug use. Respiratory changes in smokers make introduction of endotracheal and suction tubes more difficult and increase the risk for postoperative respiratory problems. Postoperative headaches may be caused by caffeine withdrawal in heavy users. During the patient's postoperative period, the nurse should be alert for signs and symptoms of drug interactions with pain medications or anesthesia and for signs of drug withdrawal.

Special precautions must be taken for the patient who is intoxicated or alcohol dependent and requires surgery. Alcohol use may be overlooked in an accident victim if there are injuries that cause CNS depression. In addition, many persons are undiagnosed as alcoholics at the time of admission for elective surgery. The patient who is alcohol dependent but is not currently drinking usually requires an increased level of anesthesia because of cross-tolerance. The intoxicated individual needs a decreased level of anesthesia because of the synergistic effect of alcohol. Whenever possible, surgery is postponed in alcohol-intoxicated individuals until the BAC is less than 200 mg%. Synergistic effects occur with anesthesia when the BAC is >150 mg%, and a patient with a BAC >250 mg% has a significantly increased surgical risk and mortality rate. Alcohol withdrawal delirium may be triggered by surgery and the cessation of alcohol consumption. Anesthetics and pain medications used in the acute period can delay withdrawal syndrome for up to 5 days postoperatively.

Pain Management

Although nurses and physicians may be reluctant to administer opioids to drug-dependent patients for fear of promoting or enhancing addictions, there is no evidence that providing opioid analgesia to these patients in any way worsens their addictive disease. When addicted patients experience any type of acute pain, the goal is to treat the pain. Addiction treatment is not the priority while the patient is in pain.

If the patient acknowledges opioid use, it is important to determine the types and amounts of drugs used. It is best to avoid exposing the patient to the drug of abuse, and effective equianalgesic doses of other opioids can be determined if daily drug doses are known. If a history of drug abuse is unknown or if the patient denies drug abuse, the nurse should consider the potential of drug abuse when normal doses of analgesics do not relieve the patient's pain or when signs of withdrawal occur. Withdrawal symptoms can exacerbate pain and lead to drug-seeking behavior or illicit drug use. Toxicology screens may be helpful in determining recently used drugs.

Severe pain should be treated with opioids, but at much higher doses than those used with drug-naïve patients. The use of one opioid is preferred. Mixed opioid agonist-antagonists such as butorphanol (Stadol), buprenorphine (Buprenex), or nubain (Nalbuphine) should be avoided because they may precipitate withdrawal symptoms. Nonopioid and adjuvant analgesics and nonpharmacologic pain relief measures may also be used. To maintain opioid blood levels and prevent withdrawal symptoms, analgesics should be provided around the clock. Supplemental doses should be used to treat breakthrough pain. Although patient-controlled analgesia (PCA) is controversial for treating addicted patients, its use may improve pain control and reduce drug-seeking behavior.

A written agreement or treatment plan that describes the pain management should be developed with the patient. The plan should ensure that pain will be treated based on the patient's perception and report of pain but also clearly outline the gradual tapering of the analgesic dose and eventual substitution of long-acting oral preparations for parenteral analgesics.

CHEMICAL IMPAIRMENT IN HEALTH PROFESSIONALS

Chemical impairment is a term used by health professionals to indicate impaired performance as a result of drug use. Drug use and abuse is a serious concern in health care professions. Alcohol is the most commonly abused drug. Others include opiates and benzodiazepines, abuse of which occurs at higher rates than in the general population, likely due to ease of access. It is estimated that 10% to 20% of nurses have substance-abuse problems and that 3% to 6% demonstrate impaired practice resulting from the use of drugs (chemicals).

Contributing Factors

Factors contributing to drug abuse among nurses have been identified as chronic fatigue, illness, responsibility for patients' responses to illness and dying, professional dissatisfaction, access to drugs, marital and child care problems, and downsizing. Other factors include nurses' false belief that knowledge of drugs provides immunity to drug problems. The issue has become less of a priority within the nursing community over the past several years, partly because the nursing shortage and workplace hazards have received more attention. Yet these issues lead to increasing stressful working conditions that put nurses at even greater risk for substance-related disorders.

Characteristics

Evidence of chemical dependence may be seen by changes in personality and behavior, job performance, and attendance. Behaviors related to influence of the drug or signs of withdrawal may also be present. Poor judgment, errors, inappropriate behavior, and illogical documentation are common in the chemically impaired nurse. Discrepancies in controlled-drug handling and records may indicate *drug diversion,* the deliberate redirecting of a drug from a patient or facility to the employee for personal use. Nurses often enable substance abuse among coworkers by covering up their mistakes or tardiness, excusing their behavior, or simply ignoring obvious signs and symptoms. When it is recognized that a nurse is impaired, help for the nurse requires sharing observations and concerns with the nurse and supervisor to provide the means for rehabilitation.

Management

Management of drug abuse in nurses largely depends on the state in which the nurse practices and the policies of the employing facility. Sometimes employment is simply terminated, allowing the nurse to work elsewhere with no resolution of the problem. Some states or facilities require that management report the nurse to regulatory agencies that may revoke licensure to practice or refer the case to the criminal justice system. These approaches are disciplinary and contribute to the reluctance by nurses to report impaired coworkers.

The tragedy of allowing a treatable disease to go untreated is costly in both human and economic terms. In an effort to help impaired nurses, the American Nurses Association, the National Student Nurse Organization, and other nursing organizations and nurse substance-abuse experts strongly advocate rehabilitation for nurses who are chemically dependent. Alternatives to discipline have been developed in most states. Alternatives include diversion programs associated with the state board of nursing that allow nurses to maintain their licenses while being monitored through recovery; state nurses' association peer assistance programs; and employee assistance programs. The goals of these programs are to protect the safety of the public, to maintain the integrity of the profession, and to ensure that the nurse is offered the possibility of treatment and rehabilitation before the license to practice is revoked or the job is terminated. Other efforts are under way to prevent chemical dependency in nurses through substance abuse educational programs, for both nursing students and nurse employees.

All nurses care for patients who are dependent on drugs, whether they are identified as dependent or not, simply because of the prevalence of drug abuse. It is important for nurses to identify and intervene with patients who are abusing drugs. Knowledge of the commonly abused drugs and treatment during intoxication, overdose, withdrawal, and cessation are critical to maintaining life and promoting healthy lifestyles.

Nursing Process
Patient-Centered Collaborative Care

Smoking (Nicotine) Cessation

Assessment
- Assess current smoking status and smoking history.
- Identify the cultural context of patient's smoking pattern.
- Determine the willingness of patient to attempt to quit.
- Have patient identify negative consequences of smoking and the potential benefits of quitting.
- Ask patient to identify any barriers or impediments to quitting.
- Identify what rewards for quitting are most important to patient.

Nursing Diagnoses
- Readiness for enhanced knowledge related to smoking cessation as manifested by a stated desire to quit smoking and a request for professional assistance

Planning
- Patient will eliminate tobacco use.

Nursing Interventions
- Set a quit date with patient, ideally within 2 weeks.
- Teach patient about the nicotine-replacement systems and other agents available to assist in smoking cessation.
- Help patient choose the best method to quit smoking based on patient preferences and anticipated benefits.
- Refer patient to support groups or programs available in the community.
- Teach patient to anticipate withdrawal symptoms and challenges of quitting.
- Advise patient to keep a list of "slips" and "near-slips" to learn to avoid their causes.
- Encourage patient to avoid environments and activities previously associated with smoking.
- Schedule frequent follow-up contacts with patient to offer encouragement; help patient deal with lapses.

Evaluation
- Evaluate effectiveness of the cessation plan, including use of drugs and support systems, to avoid relapse.
- Determine the smoking status of patient.

CRITICAL THINKING CASE STUDY

LM, a 57-year-old man, is admitted to the surgical unit in preparation for back surgery, after conservative treatment for a recent back injury has not relieved his pain. His wife tells the nurse she hopes the surgery will be successful. She confides that her husband has just been sitting around the house drinking more beer than usual, because he has not been able to work. LM appears relaxed and unconcerned about his anticipated surgery. He jokes with the nurse, telling her that his back would be cured if "a cute young thing" like her "would only rub his back."

1. What assessments of LM's alcohol use should the nurse make and communicate to the surgeon and anesthesiologist before he is further prepared for surgery?
2. How would the nurse's approximation of LM's BAC affect his surgical experience?
3. During LM's postoperative period, when will the nurse expect signs of withdrawal syndrome to occur? Explain your answer.
4. What early signs and symptoms would alert the nurse to the development of withdrawal syndrome?
5. What drug regimens might be used during LM's postoperative period to manage problems associated with his alcohol use?

NCLEX STUDY QUESTIONS

1. When caring for a patient recovering from an episode of opioid toxicity, the nurse determines that the patient has an addiction to the drug based on which finding?
   a. Physical withdrawal signs
   b. A history of daily use
   c. Craving that results in drug-seeking behaviors
   d. Intravenous rather than oral use of the drug

2. While teaching the parents of an adolescent who has been using marijuana, the nurse explains that the euphoria that results from the use of abused psychoactive substances is believed to be caused by which factor?
   a. Blockade of opioid receptors in the mesolimbic system of the brain
   b. Stimulation of the dopamine pathways in the pleasure areas of the brain
   c. Increased release of serotonin in all areas of the brain
   d. Reduction in the responsiveness of brain receptors
3. A patient hospitalized with a fractured femur following an automobile accident develops diarrhea and vomiting with abdominal cramps, chills with goose bumps, and dilated pupils. The nurse suspects that the patient is experiencing which reaction?
   a. Opioid withdrawal
   b. Alcohol toxicity
   c. Flashbacks from psychedelic abuse
   d. Barbiturate withdrawal
4. Which agent(s) will the nurse anticipate administering to a patient who has been admitted with acute alcohol intoxication? (Select all that apply.)
   a. naloxone (Narcan)
   b. thiamine
   c. lorazepam (Ativan)
   d. naltrexone (ReVia)
   e. intravenous glucose solution
   f. flumazenil (Romazicon)
5. A patient is admitted to the emergency department with acute cocaine toxicity. Which is the most important intervention by the nurse?
   a. Institute cardiac monitoring, and obtain frequent blood pressures.
   b. Monitor the patient for decreasing respiratory function and level of consciousness.
   c. Provide reality orientation with a calm, quiet approach.
   d. Administer oral fluids with caffeine to prevent withdrawal symptoms.
6. A nurse observes another nurse taking oral opioids from the medication room at the hospital. Which is the best action by the nurse?
   a. Report the finding to the nursing supervisor to enable the nurse's participation in a diversion program.
   b. Ignore the situation to protect the nurse from dismissal and possible loss of licensure.
   c. Confront the nurse and demand that the drugs be returned before someone notices their absence.
   d. Ask the nurse to request pain medications from a physician rather than stealing them from the hospital.
7. A patient is to start disulfiram (Antabuse) to help with alcohol abuse. The nurse providing medication education about the drug will include which topics in the education plan? (Select all that apply.)
   a. Importance of taking this medication every day
   b. That better results are experienced when a support group helps with adhering to treatment
   c. Common food and hygiene products containing alcohol
   d. That disulfiram treatment should be stopped 1 day before alcohol consumption
   e. That disulfiram works by disrupting the metabolism of alcohol
   f. That use of alcohol with disulfiram may cause nausea and vomiting and may even be fatal
8. A patient in the hospital is experiencing methamphetamine withdrawal. What does the nurse expect the symptoms and treatment to be?
   a. Hypertension, tachycardia, and autonomic overactivity; treated by benzodiazepines
   b. Hypersomnia, irritability; treated by supportive care including pushing food and fluids
   c. Minimal notable symptoms; no treatment needed
   d. Anxiety, insomnia, hyperactivity, and rapid, pressured speech; treated by symptom management

Answers: 1, c; 2, b; 3, a; 4, b, c, e; 5, a; 6, a; 7, a, b, c, e, f; 8, b.

CHAPTER 6

Herbal Therapies

evolve WEBSITE

- Animations
- Content Updates
- Key Points
- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Discuss at least six important points associated with herbal therapy for consumer and health care provider education.
- Compare at least six common herbs and their associated toxicity.
- Differentiate at least eight of the most common herbal therapies and the potential use for each.
- Describe the recommendations for labels on herbal products.
- Discuss the nursing implications, including patient teaching, related to herbal products.

OUTLINE

Herbal Monographs
Dietary Supplement Health and Education Act of 1994
Current Good Manufacturing Practices
Herbal Preparations
Commonly Used Herbal Remedies
  Aloe Vera *(Aloe barbadensis)*
  Black Cohosh *(Cimicifuga racemosa)*

tinctures, p. 63

It is critical for nurses to know about herbal therapy and to include herbal preparations as part of their assessment. Herbal products can have both positive and negative effects and important interactions with prescription and over-the-counter (OTC) medications. Nurses are in an excellent position to educate patients about these interactions.

An **herb**, according to MedlinePlus, is "a plant or plant part used for its scent, flavor or therapeutic properties. Herbal medicine products … are sold as tablets, capsules, powders, teas, extracts, and fresh or dried plants. However, some can cause health problems, some are not effective and some may interact with other drugs."

Herbs have long been and continue to be sources of old and new drugs: foxglove (source of digitalis), snakeroot (source of reserpine), willow bark (source of aspirin), and Pacific yew tree (source of Taxol), to name just a few. The therapeutic value of **phytomedicine** (medicine derived from plants) relates to several factors, including dosage, potency, and purity. Research into the effects of herbal medicine is increasing.

Many Americans use herbal products for therapeutic or preventive reasons. Herbal therapy has surged in popularity; marketing and media have fueled the demand, with advertisements and promotions on television, in magazines, and on the Internet. It is estimated that herbal products are used by almost one third of Americans, many of whom do not share the use of these products with their health care providers. Worldwide annual sales of herbal products represent greater than $60 billion, and the strong market is expected to continue.

Few pharmacy schools in the United States offer courses in botanical remedies, but herbal therapy is being addressed in the professional literature with increasing frequency and seriousness. Health care providers and consumers are asking questions about herbal therapy's effectiveness, potential toxicity, and reactions with conventional medications. Consumers are right to question advertisements that imply that herbs will cure anything. Herbs can be useful, but they can also be ineffectual or even dangerous (Herbal Alert 6-1).

HERBAL ALERT 6-1

Patient Responsibility

To optimize the therapeutic regimen, the patient has the responsibility to (1) consult with the health care provider before taking any herbal preparation, (2) report all herbal preparations taken to all health care providers, (3) inform health care providers of any allergy or sensitivity to any herbal products, (4) use caution if pregnant or lactating, and (5) not take a greater dose than recommended.

In 1992, Congress instructed the National Institutes of Health (NIH) to develop an Office of Alternative Medicine to support studies of alternative therapies. This office is now called the National Center for Complementary and Alternative Medicine (NCCAM). NCCAM lists current clinical trials with herbal products on their website *(www.nccam.nih.gov/research/clinicaltrials)*. The Natural Standard Research Collaboration also reviews global literature on herbal studies by clinicians and researchers. These studies are important because botanical remedies cannot be patented, so their manufacturers generally cannot justify the expenses associated with safety and efficacy testing in an already booming conventional medicine economy.

This chapter describes selected aspects of herbal therapy, including (1) herbal monographs, (2) the Dietary Supplement Health and Education Act of 1994, (3) varieties of herbal preparations, (4) the most commonly used herbs, (5) herbs used to treat selected common ailments, (6) potential hazards of herbs, (7) tips for consumers and health care providers, and (8) herbal resources.

HERBAL MONOGRAPHS

The two primary types of **herbal monographs** are therapeutic and qualitative. Therapeutic monographs contain information on use, dosage, side effects, and contraindications. Qualitative monographs have information on areas such as compliance with compounding guidelines and standards of purity. Integrating herbs into the American health care system requires both types of monographs, which the United States currently does not have.

Work to develop these monographs is in progress by several organizations, including the United States Pharmacopeia (USP), the World Health Organization (WHO), the American Herbal Pharmacopeia (AHP), the European Scientific Cooperative of Phytomedicines (ESCOP), and the German Commission E.

The German Commission E, an oversight commission in Germany, works to determine the safety of an herbal product with "reasonable certainty." The American Botanical Council has translated the German Commission E monographs into English in an effort to bring more information to the American public. Much work remains to be done related to the effects of preparations and the improvement of manufacturing and marketing processes.

Standardization is movement toward consistency and comparison of herbal preparations. A standardized herbal extract has one or multiple ingredients whose levels are guaranteed in the sold product. Examples of standardized herbal products are presented in Table 6-1.

DIETARY SUPPLEMENT HEALTH AND EDUCATION ACT OF 1994

The **Dietary Supplement Health and Education Act of 1994 (DSHEA)** clarified marketing regulations for herbal remedies. DSHEA reclassified herbals as "dietary supplements" distinct from food or drugs. Herbal supplements can be marketed with suggested dosages. Consumers are reminded that premarket testing for safety and efficacy is not required, and manufacturing is not standardized. The physiologic effects of the product can be noted, but no claims can be made about preventing or curing specific conditions. For example, a

TABLE 6-1 SELECTED HERBAL PRODUCTS WITH STANDARDIZED CONCENTRATIONS

HERB	STANDARDIZED CONCENTRATION OF ACTIVE INGREDIENT
Bilberry	25% anthanocyanosides
Feverfew	0.2% parthenolide
Ginkgo biloba	24% flavone glycosides; 6% terpene lactones
Goldenseal	8% to 12% alkaloid
Hawthorn	20% procyanidins
St. John's wort	0.13% to 0.30% hypericin
Saw palmetto	85% to 95% fatty acids

product label cannot claim that the agent "prevents heart disease," but it can say that the agent "helps increase blood flow to the heart." In addition, a disclaimer is required that indicates that the herb is not approved by the U.S. Food and Drug Administration (FDA) and that it is not meant to be used as a drug.

In January 2000, the FDA finalized rules for claims on dietary supplements, noting that supplements may make structure and function claims without FDA approval. However, it may not be claimed that the supplement can prevent, treat, cure, mitigate, or diagnose diseases. This ruling caused label changes on products but did not affect product availability or consumer access. Health maintenance claims (e.g., "maintains a healthy immune system") and claims for relief of minor symptoms related to life stages (e.g., "alleviates hot flashes") are acceptable because they do not relate to disease. Herbal products using a "may be beneficial" disclaimer rather than claims of definite benefit are appropriate legally. Dietary supplement manufacturers are still required to substantiate any claims they make.

CURRENT GOOD MANUFACTURING PRACTICES

The FDA proposed standards for marketing and labeling for dietary supplements in 2003. Known as the **Current Good Manufacturing Practices (CGMPs)**, these standards are multifaceted and require that package labels give quality and strength of all contents and products be free of contaminants and impurities. Manufacturing quality control procedures are part of the CGMPs.

Additionally, a "seal of approval" is awarded to products meeting criteria similar to the CGMPs by four organizations (the USP, ConsumerLab, National Products Association, and NSF International). The fee-based tests provide information on herbal products' identity, potency, dissolution, purity, and labeling accuracy.

HERBAL PREPARATIONS

Herbal remedies are available in a variety of preparations and forms. Following is a description of selected preparations and forms of herbs, including dried herbs, fresh oils, salves, teas, tinctures, syrups, capsules, and tablets. The consumer and health care provider must be knowledgeable about the differences in dosages between extracts and powders as well as the issues associated with standardization.

Dried herbs are fresh herbs that have had the moisture removed by sun or heat. They can be stored for about 6 months. **Extracts** are made by isolating certain components, resulting in more reliable dosing. Dissolving the herb in a solvent such as alcohol or water is a common way to prepare an extract, which may or may not be standardized. **Fresh herbs** may decay after a few days because of enzyme activity; hence they have a short life.

Oils are made by soaking dried herb in olive or vegetable oil and heating it for an extended time. The oil promotes concentration of some of the herb's active components, and it may last for months if stored correctly. These infused oils are not "essential oils" (volatile oils extracted from plants that produce an odor and stimulate taste sensations). **Salves**, semisolid fatty preparations, are made by melting a wax in oil (or crushing the herb and mixing it in a petroleum jelly base) and allowing it to cool and harden. If stored correctly, they last for several months as balms, creams, and ointments. **Teas** are made by steeping fresh or dried herbs in boiling water. Tea made from bark and roots is often simmered. It is recommended that only a 2- to 3-day supply be prepared at one time and that it be stored in the refrigerator. Teas may be used as a drink, added to baths, and applied topically in a compress. **Tinctures** are commonly made by soaking fresh or dried herbs in a solvent such as water or alcohol. Both water- and fat-soluble components are concentrated in the final form. Alcohol promotes preservation, yielding a shelf life of 1 year. Alcohol-free, glycerin-based tinctures are available for people who do not consume alcohol. **Syrups** are made by adding a sweetener, usually honey or sugar, to the herb and then cooking it. Syrups are used to treat colds, coughs, and sore throats.

Capsules commonly contain a powdered form of dried supplement, but they may hold juices or oils. They have a slower effect than liquids because of decreased absorption. They store and travel well. Tablets are similar to capsules; they are a powder compressed with stabilizers and binders.

COMMONLY USED HERBAL REMEDIES

Most herbal therapies are used for chronic conditions, are unlikely to cause harm, and may provide some relief in selected situations. This section discusses some of the more commonly used herbs.

Aloe Vera *(Aloe barbadensis)*

The juice is used externally for treatment of minor burns, insect bites, and sunburn. Fresh aloe leaves are most effective. There has been some success with the treatment of dandruff, oily skin, and psoriasis. Taken internally, aloe vera is a powerful laxative. Menstrual flow is increased with small doses.

Black Cohosh *(Cimicifuga racemosa)*

This is a popular supplement used to treat hot flashes, palpitations, and irritability (short-term menopausal symptoms; short-term use is recommended). It potentiates the effects of insulin, oral hypoglycemics, and antihypertensive drugs (Herbal Alert 6-2).

HERBAL ALERT 6-2

Black Cohosh

Do not confuse black cohosh with blue cohosh, an herbal preparation said to induce labor in pregnant patients.

Chamomile *(Matricaria recutita)*

Dried flower heads of *Matricaria recutita* are the ingredients of a popular tea for relief of digestive and gastrointestinal (GI) complaints. Chamomile tea's antispasmodic and anti-inflammatory effects on the GI tract make it useful for relief of irritable bowel syndrome and infant colic. In addition, chamomile may have sedative effects.

Chamomile tea is prepared by steeping 1 teaspoon of flower heads for 10 to 15 minutes in boiling water; suggested use is three to four times per day. An extremely rare reaction of urticaria and bronchoconstriction may occur in an individual who is allergic to daisy or ragweed-type plants. Pharmacokinetics and pharmacodynamics are not known.

Dong Quai *(Angelica sinensis)*

Dong quai, an all-purpose woman's tonic herb, has long been popular in China and Japan for the treatment of menstrual cramps and to regulate the menstrual cycle. This herb has not been well studied, and preparations are frequently mixed with fillers. Dong quai contains vitamin B_{12}, which may promote manufacture of blood cells. Rare side effects include fever and excessive menstrual bleeding. Pharmacokinetics and pharmacodynamics are not known. The recommendation is to avoid the use of this herb.

Echinacea *(Echinacea angustifolia)*

Echinacea, a popular oral and topical supplement, is used as an immune enhancer; it acts by furthering phagocytosis by means of increasing leukocytes and spleen cells and activating granulocytes. In addition, echinacea inhibits hyaluronidase activity and increases the release of tumor necrosis factor. The leaf preparation is given for respiratory and urinary tract infections. The root extract is used to treat flulike symptoms. German Commission E recommends that echinacea preparations be avoided by persons with autoimmune diseases and those with abnormal T-cell functioning (e.g., human immunodeficiency virus [HIV], acquired immunodeficiency syndrome [AIDS], tuberculosis).

Echinacea should be purchased only from reliable sources. There are many reports of fraudulent substitution with other plants and varying potency. Recommendations for duration of treatment are inconsistent. However, treatment should begin immediately with the onset of symptoms to "catch it early." German Commission E recommends the use of echinacea for up to 8 weeks; others recommend a week-long "drug holiday" (i.e., not taking the preparation for a specific time period) before continuing therapy. Pharmacokinetics is not known. Immunosuppression may occur after extended therapy.

Evening Primrose *(Oenothera biennis)*

Evening primrose is a native North American biennial plant. Oil in its seeds contains gamma-linolenic acid (GLA), a fatty acid believed to help prevent cirrhosis, eczema, premenstrual syndrome, hypertension, hardening of the arteries, and heart disease. It aids in lowering cholesterol and relieving pain and inflammation. The bark and leaves have astringent qualities, and the oil affects uterine muscles, metabolism, and the nervous system. It should not be used during pregnancy and lactation. It may lower the seizure threshold if taken with anticonvulsants; the anticonvulsant dose may need modification, or it should not be used concurrently. Pharmacokinetics and pharmacodynamics are not known.

Feverfew *(Tanacetum/Chrysanthemum parthenium)*

The plant compound parthenolide is believed to inhibit platelet aggregation and act as a serotonin antagonist in mediating vascular headaches. Feverfew is popular for prophylaxis and for relief of migraine headaches and their accompanying nausea and vomiting. Postfeverfew syndrome (fatigue, headache, joint pain, nervousness) is experienced by some. Local ulceration and irritation may result from chewing feverfew leaves. Only standardized extracts should be used. Wide variation in the amount of active compound in plants and commercial capsules is a potential dosing problem. Pharmacokinetics and pharmacodynamics are not known.

Garlic *(Allium sativum)*

Garlic is reported to lower cholesterol and triglyceride levels, decrease blood pressure, and reduce the clotting capability of blood (increases precursor of nitric oxide). It also acts as an antibiotic to treat infections and wounds both internally and externally. Warm garlic oil is used in the ear for treatment of earache. Garlic may be used for some types of heavy-metal poisoning. Pharmacokinetics and pharmacodynamics are not known.

Ginger *(Zingiber officinale)*

Ginger boosts the immune system. It is used to treat migraine headache, stomach problems, and digestive disorders, including motion sickness. Long-time use for relief from nausea is validated by modern research. In addition, it may provide relief from pain, swelling, and stiffness of both osteoarthritis and rheumatoid arthritis (dosage 500 to 4000 mg/day). Information on pharmacokinetics and pharmacodynamics is limited. Metabolites are excreted via urine within 24 hours, and it is 90% protein-bound.

Ginkgo *(Ginkgo biloba)*

Ginkgo biloba, an extract of one of the oldest plant species, is the most commonly prescribed herbal remedy worldwide. When it crosses the blood-brain barrier, ginkgo has central nervous system (CNS) effects, increasing both cerebral arterial dilation and uptake of oxygen and glucose. It assists cells during periods of hypoxia (e.g., during transient ischemic attacks) and decreases free-radical damage to neurons. In addition, there is inhibition of platelet adhesion and degranulation. German Commission E Monograph #55 lists the use of ginkgo for dementia syndromes, intermittent claudication, vertigo, and tinnitus when these symptoms are secondary to diminished blood flow. There is some evidence that ginkgo improves cognition and may be helpful in Alzheimer's disease, early stroke, and Raynaud's phenomenon. Some men take ginkgo to treat erectile dysfunction.

Ginkgo biloba is generally given as 120 to 240 mg/day in two to three divided doses for up to 90 days. Rare side effects include headache and GI disturbances. Limited information is available on pharmacokinetics and pharmacodynamics. Bioavailability is not affected by food; urinary excretion is less than 30% metabolites.

Ginseng *(Panax ginseng)*

Preparations of ginseng are taken for short-term relief of stress, to boost energy, and to give digestive support. Ginseng tends to support the immune system and assist in the prevention of chronic infections. Red Korean or Chinese ginseng may be overstimulating in chronic inflammatory conditions such as arthritis. Pharmacokinetics and pharmacodynamics are not known.

Goldenseal *(Hydrastis canadensis)*

Goldenseal is frequently used with echinacea to ward off infection and promote wound healing. Common uses include treatment of GI ulcers, mouth ulcers, bladder infection, eye and skin irritation, and postpartum hemorrhage. It is used to treat congestion associated with the common cold. In addition, it is used as a tonic and astringent. Active ingredients are deactivated in the stomach. Goldenseal is expensive and scarce; thus it is frequently adulterated with fillers. Its ability to stimulate the immune system has been questioned, and it can be toxic if overused. Goldenseal is contraindicated during pregnancy (stimulates uterus). Pharmacokinetics and pharmacodynamics are not known.

Kava *(Piper methysticum)*

Kava promotes sleep and muscle relaxation and is an antiepileptic, antidepressant, and antipsychotic. Kava also promotes wound healing. Tea can help with urinary tract infections. Kava may be used in combination with other herbs, such as valerian and St. John's wort, for relaxation. Kava may cross the placenta and be present in breast milk. In 2002, the FDA issued a consumer advisory about the potential for liver damage with kava use. Long-term use may result in a pellagra-like skin disorder that disappears when kava is discontinued. Little is known about its pharmacokinetics and pharmacodynamics.

Licorice *(Glycyrrhiza glabra)*

Licorice may have physiologic effects similar to aldosterone and corticosteroids related to glycyrrhizin, a major ingredient. Licorice may help with chronic fatigue syndrome. The deglycyrrhizinated form is used to treat ulcers. It relieves heartburn and indigestion by decreasing stomach acid; it also has a laxative effect. Side effects from excessive licorice include increased blood pressure, headache, lethargy, water retention, increased potassium excretion, and, rarely, heart failure. Licorice root is considered safe in dosages of 5 to 15 mg when taken as tea. Its recommended use is limited to 6 weeks. Pharmacokinetics and pharmacodynamics are not known (Herbal Alert 6-3).

HERBAL ALERT 6-3

Black Licorice

Consuming 2 ounces of black licorice daily for 14 days may cause arrhythmia in people age 40 years and older.

Milk Thistle *(Silybum marianum)*

This herbal extract has the remarkable ability to prevent damage to liver cells and stimulate regeneration of liver cells. Milk thistle is widely used in Europe to treat hepatitis, cirrhosis, and fatty liver associated with drug and alcohol abuse. Pharmacokinetics and pharmacodynamics are not known.

Peppermint *(Mentha piperita)*

Peppermint stimulates appetite and aids in digestion when taken internally. The digestive tract is protected by the tannins, and peppermint is used in the treatment of bowel disorders. Hot peppermint tea stimulates circulation, reduces fever, clears congestion, and helps restore energy. Peppermint oil is an effective treatment for tension headache when rubbed on the forehead. In research in Germany, peppermint has been shown to be comparable with acetaminophen (extra-strength Tylenol) in relieving headache. Pharmacokinetics and pharmacodynamics are not known.

Sage

Sage has a long history of use for medicinal and culinary purposes. Sage tea is used as an aid for sore throat and cough; it may also be used as a gargle to decrease inflammation of mouth, gums, and throat. According to clinical studies, antibacterial, antifungal, and antiviral effects are found in sage and result in its medicinal effects. Its recommended use is limited to 2 weeks to avoid the toxic effects of tannins.

St. John's Wort *(Hypericum perforatum)*

Current research suggests that St. John's wort is not effective when used by individuals with moderate to severe depression. Botanical experts indicate that it is to be used for mild depression. St. John's wort has at least 10 pharmacologically active components. The compound used for standardization is hypericin. Researchers recommend that prospective trials be conducted to compare St. John's wort with standard antidepressant medication and to identify dosages, effectiveness in different stages of depression, and implications of long-term use. St. John's wort has been nicknamed "herbal Prozac" because of its great popularity in the United States and its use as a "tonic" for the nervous system. St. John's wort is used in combination with yarrow to treat enuresis. When taken concomitantly with a prescription antidepressant, an adverse effect of St. John's wort may be suicidal ideation. This herbal remedy is considered a dietary supplement in the United States and has not been FDA approved. In Germany, it is licensed for relief of anxiety, depression, and insomnia. The 1984 German Commission E monograph on hypericin indicated that the agent was an experimental monoamine oxidase inhibitor (MAOI) for use in depression, anxiety, and psychogenic disturbances. The mechanism of action is unknown.

The usual dose of St. John's wort is 300 mg of extract three times a day (standardized to 0.3% hypericin). A tea can be prepared from 1 to 2 teaspoons of herb steeped for 10 minutes. One to two cups of tea per day for 4 to 6 weeks is recommended. Users should apply sunscreen freely when outdoors, although phototoxicity has not been reported in humans. St. John's wort crosses the blood-brain and placental barriers and may enter breast milk. Minimal information is known about the pharmacokinetics and pharmacodynamics.

Saw Palmetto *(Serenoa repens)*

Double-blind studies indicate that saw palmetto relieves symptoms of benign prostatic hypertrophy and urinary conditions. Saw palmetto has earned the nickname "plant catheter." Individuals who use saw palmetto can get false-negative test results for PSA. Other indications for this herb include use as an expectorant and a treatment for colds, asthma, bronchitis, and thyroid deficiency. The recommended dose is 160 mg of standardized extract twice a day. Pharmacokinetics and pharmacodynamics are not known.

Valerian *(Valeriana officinalis)*

Valerian, a mild sedative and sleep-inducing agent, has an effect similar to benzodiazepines. It is popularly known as "herbal Valium." Most researchers report no hangover effect. A "dirty socks" odor is related to the dried plant, resulting in low risk of overdose. Preparations from fresh root are reported to be better relaxants and have a sweet aroma. There have been no reports of habituation and addiction. Drowsiness may occur, as with any relaxant. The dosage depends on the symptoms, such as insomnia and anxiety. To treat insomnia, 400 mg of tincture extract or 2.5 to 5 mg of solid extract is recommended at bedtime. For anxiety, a tea steeped with 1 teaspoon of dried herb is taken several times a day. About 5% to 10% of users report a stimulant effect. Pharmacokinetics and pharmacodynamics are not known.

Table 6-2 describes aspects of selected herbs. Vitamins and elements commonly used in conjunction with herbal therapy are vitamins B_6, A, C, and E; selenium; and zinc. The American Herbal Products Association has categorized herbal products based on "reasonable use" into four classes. See the note at the end of Table 6-2 for a description of the classes.

POTENTIAL HAZARDS OF HERBS

Both consumers and health care providers should remember that although herbs are natural substances, they are not necessarily safe. No preparations are safe in all situations, and herbs are no exception. Consumers and health care providers must be alert to potential hazards with herbal therapy. It is essential that the health care provider get a complete list of all of the herbal preparations the patient takes, the reason they are taken, and their perceived effectiveness. This assessment should be updated regularly along with information on the patient's prescription and OTC drug use.

Patients may not disclose use of herbal products to health care providers for a variety of reasons, including the sense that the health care provider is biased against or not knowledgeable about herbal products or the belief that these products are not considered medications. Herbal use should be encouraged as an "integrative" modality rather than as a replacement for a medical therapy. The patient must inform the health care provider of any use of herbal products to ensure that they do not interfere with the use and actions of prescribed medication. When taking a health history, it is important for the nurse collecting data to ask about these remedies and to specifically mention homeopathic remedies as well as teas (infusions), tinctures, tablets, and herbs in dried forms.

Without regulations, manufacturers of herbal products may make unsubstantiated claims on their labels. Companies manufacturing for drugstores and grocery stores are suspect. Their supplements may contain many fillers not mentioned on the labels. However, several companies (e.g., Nature's Way, Nature's Sunshine, Gaia) do label their products accurately and include in the bottle only what the ingredient list indicates.

Contamination is another area of concern, most likely resulting from lack of standards in the manufacture and regulation of herbs. It is the responsibility of consumers to educate themselves about herbs before use and to purchase products only from reputable dealers. Determination of the purity and concentration of a particular product can be done only through assays, a costly process; thus, most products have not had appropriate human toxicological analysis.

Interaction with conventional drugs is another area in which health care providers should be alert. For example, an additive effect of digoxin can result from the use of the laxative herbs cascara and senna. Also, elevation of the blood level of lithium may result from juniper, dandelion, and other herbs with diuretic properties. Patients at high risk for interactions include older adults and those taking three or more drugs for chronic conditions. See Table 6-3 for selected herbal ingredients and drug interactions.

Text continued on p. 75

TABLE 6-2 SUMMARY OF SELECTED HERBS*

HERB	ACTIONS AND USES	DOSAGE	INTERACTIONS/PRECAUTIONS	SIDE/ADVERSE EFFECTS
Common and *Botanical* Names ***Class and Part Used***				
aloe/aloe vera *Aloe barbadensis* Class 1 Leaf gel Class 2b/2d Dried, juice Class 2d Topical bladelike leaf	Uses: Internal for constipation; externally to relieve pain and promote healing of burns, wounds, sunburn, psoriasis	Internal: Tincture/extract: 50-300 mg External: t.i.d. or PRN	Internal use contraindicated if pregnant or lactating, and in children <12 y Consult with HCP before taking if have ulcerative colitis or Crohn's disease or if taking cardiac glycosides, antiarrhythmics, thiazide diuretics, licorice, or corticosteroids Monitor electrolytes	Internal: Overdose/long-term use: arrhythmias, neuropathies, edemas, albuminuria, hematuria (side effects are rare)
bilberry *Vaccinium myrtillus L.* Class 4 Extract of dried fruit and leaf	Uses: Fruit may promote healthy vision, increase visual pigment regeneration; decrease diarrhea in children Leaf used for diabetes, arthritis, dermatitis, gout	Fruit extract: 80-160 mg t.i.d. (St: 25% anthocyanosides) Leaf: no information	Avoid use if pregnant or lactating, and in children No reported significant interaction with fruit Leaf: May decrease blood sugar and triglyceride levels; may increase action of anticoagulants and NSAIDs; monitor for dose adjustments	Leaf: Long-term higher doses (in animals): anemia, icterus, excitation, death
black cohosh (bugwort, snakeroot, squaw root) *Cimicifuga racemosa* Class 2b/2c Root	Suppresses luteinizing hormone, optimizes estrogen levels Uses: Antispasmodic, astringent, diuretic, vasodilator, PMS, dysmenorrhea, infertility, menopausal symptoms	Cap/tab: 20 mg b.i.d. Tincture: 2-5 mg b.i.d.	Avoid use if pregnant or lactating, and in children Limit use to 6 mo; no data on long-term use Under supervision of qualified herbalist, increases action of antihypertensives; may alter effects of HRT May decrease iron absorption	Higher doses: dizziness, headache, nausea, change in heart rate
chamomile (green chamomile) *Matricaria recutita* Class 2b Dried flower tops	Stimulates normal digestion, antiinflammatory, antispasmodic, mild sedative, mild diuretic, mild antibacterial with topical use Uses: Anxiety, insomnia, indigestion, inflammatory skin conditions	*Between meals:* Cap/tab: 2-3 g t.i.d., Tea: 1-4 c/d Tincture: max: 1 tsp t.i.d.	Avoid use if allergic to daisy family (e.g., ragweed, asters, chrysanthemums) May increase effects of sedatives and interfere with action of anticoagulants H/F, H/H: None known	None known
cranberry *Vaccinium macrocarpon Ait.* Class 4 Berries	Prophylaxis (not treatment) of urinary tract infections; to treat kidney stones	Extract: 300-400 mg concentrated juice b.i.d. Cocktail: 300 mL/d commercial cranberry juice	Caution: Avoid use with oliguria and anuria. Patients with DM should use sugar-free cranberry juice; lactating patients, children <12 y, and patients with history of oxalate kidney stones limit to 1 L/day. H/D, H/F, H/H: None known	Doses of >3 L/day may produce diarrhea

Continued

TABLE 6-2 SUMMARY OF SELECTED HERBS—cont'd

HERB	ACTIONS AND USES	DOSAGE	INTERACTIONS/PRECAUTIONS	SIDE/ADVERSE EFFECTS
dong quai *Angelica Sinensis* Class 2b (root) Roots, rhizomes	Phytoestrogen activity; vasodilation, small muscle relaxation Decreased IgE antibody production Uses: PMS, menopausal symptoms, cardiovascular support	Tea: 1-4 c/d (equivalent 1-2 g dried herb) Tincture: 0.5-4 mL, Max: 6 times a day	Caution: Avoid use with prescription anticoagulants, history of bleeding disorders, or if pregnant or at risk for breast cancer H/D: additive bleeding effect with anticoagulants, aspirin, NSAIDs	Rash and photosensitivity; fever, bleeding
echinacea (purple coneflower) *E. purpura; E. angustifolia, E. pallida* Class 1 (root/seed) Aerial parts of *E. pallida;* root of *E. pallida* and *E. angustifolia*	Stimulates immune system; antibacterial, antiviral, antipyretic Antifungal as topical Uses: Prevention and early treatment of colds and flu; recurrent respiratory, ear, and urinary tract infections Topical: Canker sores, fungal infections Investigational use: Stimulate immune system of HIV/AIDS patients.	Tab: 500 mg-1 g t.i.d. Tea: 1-5 c/d Tincture: max: 2 tsp t.i.d.	Short-term use: 2 wk; 8 wk if low dose; may be hepatotoxic if taken continuously Avoid use with immunosuppressants such as corticosteroids (may counteract) and with chronic systemic disease of immune system (e.g., SLE, HIV, TB, MS) Safety not determined in pregnancy, lactation, and children <2 y	Lozenge/tincture: Temporary numbness or tingling of tongue Cross-sensitivity in patients allergic to daisy family, GI upset, diarrhea
evening primrose *Oenothera biennis* Class 4 Oil of seed	Natural estrogen promoter Uses: PMS, problems with synthesis of fatty acids, abnormal prostaglandin production, diabetic neuropathies, chronic inflammatory conditions (eczema), overactive immune systems	Take with meals (increases absorption): Oil: PMS: 3-6 g/d for 6 mo, 14 days before menses Inflammatory conditions: 4-8 g/d for 3-4 mo MS: 500 mg/d for 3 wk with exacerbation	Avoid use if pregnant or lactating May lower seizure threshold if taken with anticonvulsants; anticonvulsant dose may need modification, or do not use concurrently H/F, H/H: None known	GI upset, nausea, headache, rash Immunosuppression with long-term use
feverfew *Tanacetum parthenium; chrysanthemum parthenium* Class 2b (whole herb) Leaves, flowering tops	Interferes with platelet aggregation, inhibits release of serotonin from platelets, blocks proinflammatory mediators, digestive relaxant Uses: Prevention and long-term management of migraine headaches; rheumatoid arthritis; menstrual problems; allergies	Cap/tab (at least 2% parthenolide) 125 mg/d; increase to 1-2 g with acute attack	May be 4-6 wk before effect; use continuously for best outcome Cross-sensitivity to plants in daisy family Avoid use if pregnant or lactating, with prescription anticoagulants, and in children <2 y Consult HCP before use if taking prescription NSAIDs (decreases effectiveness) May interfere with SSRI antidepressants (e.g., Prozac)	Possible gastric distress or mouth sores if using raw leaves; muscle stiffness; may have rebound headache if discontinued abruptly
garlic *Allium sativum* Class 2c Bulb	Detoxifies body and increases immune function; decreases platelet aggregation; increases HDL and decreases cholesterol and triglycerides, broad antimicrobial activity, mild antihypertensive; hypoglycemia Uses: Hypercholesterolemia, mild HTN, colds and flu	Caps (enteric coated): (ED of 5000 mcg/d of allicin in divided doses) Raw garlic clove is best source; minimum: 1/d	Avoid use if pregnant or lactating (may stimulate labor or cause infant colic) and in hypothyroidism Blood pressure may decrease in 30 min and return to baseline in about 2 hr Caution: Use with caution with prescription anticoagulants because of increased fibrinolysis and decreased platelet aggregation; modify antidiabetic doses H/F: None; H/H: Acidophilus decreases absorption of garlic	Heartburn, flatulence, gastric irritation, decreased RBCs; dizziness, diaphoresis

ginger *Zingiber officinale* Class 1 (fresh root) Class 2b/2d Dried root, rhizome	Stimulates digestion, increases bile and motility; antispasmodic; decreased platelet aggregation; decreases absorption and increases excretion of cholesterol; antioxidant Uses: Nausea, pregnancy morning sickness (short term, low dose ONLY); motion sickness; gastric protection with NSAIDs	Take with food Cap/tab/tea: 2-4 g in 2-3 divided doses For motion sickness, start 2 d to 2 hr before travel Inflammatory joint disease: 4 g in 2-3 divided doses Nausea (pregnancy related): 1 g in divided doses for 1-4 d Tincture: 1.5-3 mL in 8 oz juice q.i.d., PRN	Avoid long-term use with pregnancy, thrombocytopenia (abortifacient in large amounts) Caution: Use with caution with prescription anticoagulants (additive effect) Consult with HCP before use if have gallstones May increase absorption of all PO medications H/F, H/H: None known	May cause gastric discomfort if not taken with food; anorexia
Ginkgo biloba *Gingko folium* Class 1 (leaf) Leaves	Antioxidant; peripheral vasodilation and increased blood flow to CNS, reduces platelet aggregation Uses: Allergic rhinitis, Alzheimer's disease, anxiety/stress, dementia, Raynaud's disease, tinnitus, vertigo, impotence, poor circulation; altitude sickness	Cap/tab: 120-240 mg/d in 2-3 divided doses (standardized to at least 24% ginkgo flavone glycosides and 6% Terpene lactones) Tincture: 5-10 mL b.i.d., t.i.d. Circulation/memory: 120 mg/d in 2-3 divided doses Alzheimer's dementia, tinnitus: up to 240 mg/d in 2-3 divided doses	Effects seen in 2-3 wk; 12-wk course recommended Avoid use if pregnant or lactating, in children, and with MAOIs Caution: Use with caution with prescription anticoagulants; monitor bleeding and prothrombin times. Use with extra caution if using ginger, garlic, or feverfew May increase BP if used with thiazide diuretics Discontinue use 2 wk before surgery Ginkgo fruit may result in severe rash; seeds are toxic H/F, H/H: None known	Initially, mild transient headache that usually stops in 2 d; mild gastric distress Toxicity: vomiting, diarrhea, dermatitis, irritability
ginseng, eleuthera, or Siberian *Eleutherococcus senticosus, Acanthopanax senticosus* Class 2b/2c/2d Root	Supports adrenal glands, enhances energy levels by inhibiting alarm phase SNS response, stimulates RBC production, decreases blood sugar levels, protects from cellular mutation from carcinogens Uses: Cold and flu prevention, adaptation to stress, chronic fatigue syndrome, SLE, HIV, mental fatigue and physical exhaustion, following chemotherapy or radiation treatments, recovery from chronic or long-term illness	Cap/tab: 2-3 g/d in 3-4 divided doses Tea: 1-4 c/d Tincture: 5-20 mL/d in 3-4 divided doses	Take for 6-8 wk; then 1 wk drug holiday, and resume for total of 3 mo Avoid use with BP >170/90, if pregnant or lactating, in children, and with bipolar or psychic disorders, DM, and anticoagulants (may increase or decrease anticoagulants, dependent on species) May increase effects of caffeine and HRT, falsely elevate digoxin levels, and interact with antipsychotic drugs H/F: Overstimulation may occur with caffeinated coffee, cola, and tea; H/H: None	Hypertension, palpitations, occasional diarrhea, possible insomnia if taken at bedtime Ginseng abuse syndrome: Edema, insomnia, hypertonia; may be life threatening

Continued

TABLE 6-2 **SUMMARY OF SELECTED HERBS—cont'd**

HERB	ACTIONS AND USES	DOSAGE	INTERACTIONS/PRECAUTIONS	SIDE/ADVERSE EFFECTS
goldenseal *Hydrastis canadensis* Class 2b Root, rhizome	Stimulates immune system and bile secretion, antipyretic, broad-spectrum antibiotic activity Uses: For infection: respiratory, digestive, urinary tract, mucous membranes, cholecystitis, cirrhosis	Cap/tab: 2-4 g/d in divided doses (standardized to 8%-12% alkaloid content)	Avoid use if pregnant or lactating, with HTN, and in children Higher dosing >5-7 d may increase liver enzymes or malabsorption of B vitamins May decrease effect of heparin, anticoagulants, cardiac glycosides; increased effect of antiarrhythmics, antihypertensives, beta blockers, and CNS depressants Caution: Use with caution in patients with cardiovascular disease, DM, or glaucoma	High doses may be hepatotoxic Toxicity: CNS depression, restlessness, seizures, cardiovascular collapse Endangered plant species
hawthorn *Crataegus laevigata, C. oxycantha, C. monogyna* Class 1 Ripe fruit, leaves, flowers	Peripheral dilation and increased coronary circulation, improves cardiac oxygenation, antioxidants, mild diuretic, decreases proinflammatory substances Uses: Mild HTN, early HF, stable angina	Cap/tab: 100-900 mg/d in divided doses (standardized to 20% procyanidins) Average dose: 100-250 mg t.i.d. Tea: 2.5-5 mL t.i.d. Tea: 1 c t.i.d. (4-5 g dried/day)	May need to modify doses of beta blockers, digitalis, and ACE inhibitors Increased effects of digitalis, beta blockers, ACE inhibitors, and CNS depressants High doses contraindicated with chronic atrial fibrillation and hypotension from dysfunction of valve H/F: None known; H/H: increases action of Lily of the Valley	Hypotension, fatigue Sedation, nausea, vomiting, anorexia
kava *Piper methysticum* Class 2b/2c/2d Dried rhizome, roots	CNS sedation without loss of mental acuity or memory Uses: Anxiety, insomnia, skeletal muscle spasm Good with psychotic disorders, no risk of tolerance	Cap/tab: Anxiety: 50-100 mg up to t.i.d. Insomnia: 180-210 mg at bedtime (standardized to 70% kavalactones) Max: 300 g/wk	Avoid use if pregnant or lactating, with parkinsonism, and if taking levodopa; not for young children Avoid alcohol use and if patient needs to be alert or will operate machinery Increases CNS-sedating drugs, especially benzodiazepines Fat soluble, so may have delayed effects H/F: increased absorption when taken with food; H/H: None known Unstable gait, numb tongue, mild GI upset	Leaf: Long-term higher doses (in animals): anemia, icterus, excitation, death High doses: may cause loss of balance, pulmonary hypertension May cause liver toxicity Banned in several European countries Use >3 mo may turn skin yellow: discontinue drug if HTN, headache, weakness
licorice *Glycyrrhiza glabra* Class 2b/2c/2d (root) Root, leaf	Antiinflammatory, antibacterial, antiviral, hepato- and gastric-protective, antidepressant, estrogenic, laxative Uses: Viral infection, upper respiratory infection, inflammation, Addison's disease, depression, ulcers Topically: Herpes, psoriasis, eczema DCL: IBS, mouth ulcers	Cap/tab: 200-600 mg glycyrrhizin in 3 divided doses; max: 4-6 wk Tea: 3 c/d (equivalent to 1-2 g/d) Tincture: 2.5-5 mL t.i.d. DGL: 300-380 mg; max: 1200 mg/d in chewable form 20 min before meals for 8-16 wk	Avoid use if pregnant or lactating, with HTN, with kidney or liver disorders, or if at risk for hypokalemia; avoid in children Caution with DM Increased aldosterone effect with increasing dose and duration Antagonizes antihypertensive drugs and spirolactone Potentiates corticosteroids and digitalis H/F: none known; H/H: may cause hypokalemia if used with aloe vera	Doses >5000 mg/d result in aldosterone-like syndrome that reverses when herb is discontinued

milk thistle (Mary thistle, wild artichoke) *Silybum marianum* Class 1 Seeds of dried flowers	Increased regeneration of liver cells; increases antioxidant activity Uses: Liver disease (hepatitis), cholecystitis, psoriasis	Cap/tab: Initially: 500 mg/d in 3 divided doses for 6-8 wk With improvement: 120-240 mg/d in divided doses; may take 7-10 d for effect; 4-8 wk if liver is diseased with alcohol Tincture: 1 mL t.i.d. (avoid ETOH-based tinctures)	Avoid use if pregnant or lactating, in children, and with drugs metabolized by P-450 enzyme Does not reverse cirrhotic liver changes, but may slow the disease and increase quality of life H/F, H/H: None known	Diarrhea first days of therapy, nausea, vomiting, menstrual changes
peppermint *Mentha piperita, var. officinalis* or *vulgaris* Class 4 Aerial parts	Antispasmodic, increase bile flow, carminative, external analgesic Uses: IBS, indigestion, cholecystitis, infant colic, nasal decongestant Topically: Musculoskeletal pain, itching, colds	Cap/tab: enteric coated: 1-2 t.i.d. between meals Tea: 2-3 c/d (equivalent 3-6 g dried herb) Tincture/oil: 6-12 gtts/d diluted in divided doses	Consult HCP before taking if have cholecystitis or obstructed bile duct No known drug interactions; may interfere with iron absorption	None known
psyllium *Plantago psyllium* Class 4	Uses: Laxative, treatment of hemorrhoids, colitis, Crohn's disease, IBS Herb of longevity, poultice: wound healing effects	½ tsp soaked in water for 15-60 min at bedtime with at least 8 oz water PO extract: 1-4 mL t.i.d.	Major ingredient in Metamucil May decrease lithium absorption Avoid use if pregnant or lactating, and in children	None known
sage *Salvia officinalis* Class 2b/2d (leaf) Whole plant	Gargle tea for sore throat, dries up mother's milk, decreases hot flashes Antidepressant and antiviral activity	Take with food Cap/tab: (standardized to at least 0.1% hypericin) 300 mg t.i.d.	Limit use to 2 wk to avoid toxic effects of tannins Caution patients with DM and seizure disorders	Nausea, vomiting, anorexia, oral irritation
St. John's wort *Hypericum perforatum* Class 2d Flowers	Uses: Mood swings, mild to moderate depression, anxiety, sleep disorders Topically: Burns/wounds	Tea: 1-2 c/d for 4-6 wk Tincture: 1-2 mL t.i.d.	Long-term use recommended; effects seen in 4-8 wk Avoid use if pregnant or lactating; with prescription antidepressants, MAOIs, and indinavir; and in children <2 y May decrease effect of digoxin related to bioavailability Monitor serum digoxin levels Use with amphetamines, trazodone, or tricyclic antidepressants may cause serotonin syndrome Interferes with absorption of iron and other minerals; high doses may increase liver enzymes	Skin photosensitivity, headache, occasional GI upset, dry mouth, dizziness, confusion

Continued

TABLE 6-2 SUMMARY OF SELECTED HERBS—cont'd

HERB	ACTIONS AND USES	DOSAGE	INTERACTIONS/PRECAUTIONS	SIDE/ADVERSE EFFECTS
saw palmetto *Serenoa repens, Sabal serrulata* Class 4 Berries	Decreases size of prostate; increases breakdown of estrogen, progesterone, and prolactin: antiandrogenic Diuretic Uses: BPH, chronic cystitis; sexual potency	Cap/tab: 230 mg/d in 1-2 doses (standardized to 85%-95% fatty acids) Tea: 1 c t.i.d. (equivalent dose 1-2 g/d) Liquid extract: 5-6 mL daily	Recommend 45-90 d of treatment; effects seen after 30 d. If effective, may take long term Avoid use if pregnant or lactating, in children, and in patients with breast cancer Effectiveness of prophylactic treatment not shown May interfere with PSA test; discontinue use 1-2 wk before test May increase or decrease effects of antiinflammatories and immunostimulants; may antagonize hormone therapy	Headache, dysuria, back pain Gastric disturbance (rare)
valerian *Valeriana officinalis* Class 1 Root	Sedative/hypnotic, antispasmodic, increases deep sleep Uses: Insomnia, stress headaches, mild anxiety, muscle cramps and spasms	Cap/tab: (standardized to 0.5% essential oils, equivalent to 2-3 g up to b.i.d.) Tea: 1-3 c/d or at bedtime Tincture: 1-3 mL; may repeat 2-3 times over 6 h	Effects may take several doses For long-term use; monitor liver function, and discontinue use if elevated Avoid if pregnant or lactating, in children, and with prescription sedative/hypnotics, MAOIs, and anticoagulants Increased sedative effect with barbiturates; negates effects of phenytoin Foul smell; no dependence or tolerance	Anxiety, headache, occasional GI upset and hangover effect with high doses, CNS depression

ACE, Angiotensin-converting enzyme; *AIDS,* acquired immunodeficiency syndrome; *b.i.d.,* twice a day; *BP,* blood pressure; *BPH,* benign prostatic hypertrophy; *c,* cup; *cap,* capsule; *CNS,* central nervous system; *d,* day; *DCL,* deglycyrrhizinated licorice; *DM,* diabetes mellitus; *ED,* effective dose; *Eq,* equivalent to; *ETOH,* alcohol; *GI,* gastrointestinal; *HCP,* health care provider; *H/D,* herb-drug interaction; *HDL,*high-density lipoprotein; *H/F,* herb-food interaction; *HF,* heart failure; *H/H,* herb-herb interaction; *HIV,* human immunodeficiency virus; *HRT,* hormone replacement therapy; *HTN,* hypertension; *IBS,* irritable bowel syndrome; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *mo,* month; *MS,* multiple sclerosis; *NSAIDs,* nonsteroidal antiinflammatory drugs; *PMS,* premenstrual syndrome; *PO,* orally; *PRN,* as needed; *RBCs,* red blood cells; *SLE,* systemic lupus erythematosus; *SNS,* sympathetic nervous system; *SSRI,* selective serotonin reuptake inhibitor; *St,* standardized to; *tab,* tablet; *TB,* tuberculosis; *t.i.d.,* three times a day; *wk,* week; *y,* year; >, greater than; <, less than.

Table revised by Joseph I. Boullata, Pharm D, BCNSP.

*The American Herbal Products Association (described in the *Botanical Safety Handbook*) has categorized herbal products based on "reasonable use" of the herb into the following four classes: **Class 1,** herbs that can be safely consumed when used appropriately; **Class 2,** herbs for which the following use restrictions apply unless otherwise directed by an expert qualified in the use of the herbal substance: for external use only, not to be used during pregnancy, not to be used while nursing, and other specific use restrictions as noted; **Class 3,** herbs for which significant data exist to recommend the following labeling: "To be used only under the supervision of an expert qualified in the appropriate use of this substance." Labeling must include proper use information as follows: Dosage, contraindications, potential adverse effects and drug interactions, and any other relevant information related to safe use of the substance; **Class 4,** herbs for which insufficient data are available for classification.

TABLE 6-3 SELECTED HERB-DRUG INTERACTIONS*

HERBAL INGREDIENT: COMMON AND BOTANICAL NAMES	DOCUMENTED DRUG INTERACTION	COMMENT	POTENTIAL DRUG INTERACTION	COMMENT
alfalfa *(Medicago sativa)*	—	—	anticoagulants	⇓ Drug effect
			oral contraceptives	⇓ Drug effect
aloe *(Aloe vera)*	—	—	antidiabetics	⇑ Drug effect
			antiplatelets	⇑ Drug effect
			digoxin	⇑ Drug effect
			diuretics	⇑ Hypokalemia
angelica root *(Angelica sp.)*	—	—	warfarin	⇑ Drug effect
arnica flower *(Arnica montana)*	—	—	warfarin	⇑ Drug effect
astragalus *(Astragalus membranaceus)*	—	—	cyclophosphamide	⇓ Drug effect
betel nut *(Areca catechu)*	fluphenazine	⇑ Drug toxicity	—	—
bilberry *(Vaccinium myrtillus)*	—	—	anticoagulants	⇑ Drug effect

	SSRIs	Serotonin syndrome		
	simvastatin	⇓ Drug level		
	tacrolimus	⇓ Drug level and effect		
	talinolol	⇓ Drug level		
	theophylline	⇓ Drug level		
	voriconazole	⇓ Drug level		
	warfarin	⇓ Drug effect		
saw palmetto *(Serenoa repens)*	—	—	hormone therapy	⇓ Drug effect
			warfarin	⇑ Drug effect
schisandra *(Schisandra chinensis, S. sphenanthera)*	midazolam	⇑ Drug effect	CYP3A substrate	⇑ Drug effect
	tacrolimus	⇑ Drug effect	P-glycoprotein substrate	⇑ Drug effect
	talinolol	⇑ Drug effect		
senna *(Cassia senna)*	—	—	corticosteroids	⇑ Hypokalemia
			digoxin	⇑ Drug effect
soy (Glycine max)	warfarin	⇓ Drug effect	—	—
uva ursi *(Arctostaphylos uva ursi)*	—	—	iron	⇓ Drug absorption
valerian *(Valeriana officinalis)*	barbiturates	⇑ Drug effect	antiepileptics	⇑ Drug effect
			CNS depressants	⇑ Drug effect
willow bark *(Salix spp.)*	—	—	warfarin	⇑ Drug effect
yohimbe *(Pausinystalia yohimbe)*	—	—	antihypertensives	⇓ Drug effect
			MAOIs	⇑ Hypertension

MAOI, Monoamine oxidase inhibitor; *RTI,* reverse transcriptase inhibitor.
*Interaction risk will depend on patient age, sex, genotype, and comorbid conditions as well as herb or drug dosage form, composition, quality, and duration of use.
Table revised by Joseph I. Boullata, PharmD, BCNSP.

Herbal products can also affect laboratory test results. One significant interaction is the effect of herbal products on blood coagulation as measured by the International Normalized Ratio (INR) system. Examples of herbs that that may decrease INR include St. John's wort, yarrow, and green tea (dose dependent). Herbs that may increase INR and put the patient at increased risk for bleeding include bilberry, black cohosh, chamomile, dong quai, feverfew, garlic, kava kava, and milk thistle.

Not all compounds are safe via all routes. For example, comfrey *(Symphytum officinale)* has both internal and external preparations. Internal use is discouraged because hepatic damage may be fatal. For external use, comfrey is used as an ointment for relief of swelling associated with abrasions and sprains.

Many products have significance for patients facing surgery because they may interfere with the absorption, breakdown, and excretion of anesthetics, anticoagulants, and other surgery-related medications (Herbal Alert 6-4). For example, valerian may increase or prolong the sedative effects of anesthetic agents. Echinacea and St. John's wort have the potential of immunosuppression required for transplant surgeries. Consult the health care provider about the length of herb-free "washout" before surgery. Guidelines reflective of the complexities of surgery related to herbal products are needed.

HERBAL ALERT 6-4

Anticoagulants

The following commonly used herbal products have been reported to interfere with anticoagulants: bilberry, cat's claw, chamomile (German), dong quai, feverfew, garlic, ginseng, ginger, ginkgo, and licorice.

Herbal product advocates have petitioned the FDA to reconsider herbal dietary supplement classification and change to a drug model consistent with European herbal regulations. The FDA is formulating rules that set standards for preparing and labeling dietary supplements to enable the consumer to make more informed choices, for example, the appropriate dosage. For dietary supplement alerts and safety information, visit *www.fda.gov/Food/Dietary/Supplements/Alerts/default.htm*.

TIPS FOR CONSUMERS AND HEALTH CARE PROVIDERS

The following are guidelines for prudent use of herbs:

- Do not take herbs if pregnant or attempting to become pregnant.
- Do not take herbs if nursing.
- Do not give herbs to infants or young children.
- Do not take a large quantity of any one herbal preparation.
- Do not delay in seeking care from the health care provider for persistent or severe symptoms.
- Buy only preparations that have the plant and its quantity listed on the packet.
- Use only herbs that have been bought currently and are fresh.
- Contact the health care provider before stopping use of a prescription medication.
- Store herbal remedies in a cool, dry, dark place; dark containers are preferred.
- Be wary of unsubstantiated claims of "miracle cures."

It is essential that both consumers and health care providers become aware of several crucial factors before trying herbal therapy:

- Consumers must regard herbs as medicines; more is not necessarily better.
- Herbs are not placebos.
- Most herbal remedies are less potent than conventional drugs. However, when prescription or OTC drugs and herbs with similar actions are combined, there is an increased risk of adverse reactions.
- Results may come faster with conventional medicine.
- Safety, efficacy, and dosage are important; multiple reliable sources should be consulted.

Labeling of herbal products is an important safety aspect. The following information should be on the label of herbal products:

- Scientific name of the product and parts of the plant used in preparation
- Manufacturer's name and address
- Batch and lot number
- Dates of manufacture and expiration; many products have a short shelf life

HERBAL RESOURCES

Many herbal resources are available on the Internet. The reader must evaluate each website and decide if the information is credible and appropriate. Following are a few examples of the many Internet resources that provide herbal information.

- American Botanical Council: *www.herbalgram.org*
- NCCAM Clearinghouse: *www.nccam.nih.gov*

The NCCAM Clearinghouse provides information on complementary and alternative medicine (CAM) and NCCAM, including publications and searches of federal databases of scientific and medical literature. The Clearinghouse does not provide medical advice, treatment recommendations, or referrals to practitioners.

- U.S. Food and Drug Administration (FDA): *www.fda.gov*
- Office of Dietary Supplements (ODS), NIH: *www.ods.nih.gov*
- CAM on PubMed: *www.nccam.nih.gov/camonpubmed*

CAM on PubMed is a service of the National Library of Medicine (NLM). PubMed contains publication information and (in most cases) brief summaries of articles from scientific and medical journals.

- U.S. Library of Medicine's MedlinePlus: *www.nlm.nih.gov/medlineplus/herbalmedicine.html*
- The Cochrane Database of Systematic Reviews: *www.cochrane.org/reviews/*

The Cochrane Database of Systematic Reviews is a collection of evidence-based reviews produced by the Cochrane Library, an international nonprofit organization. Reviews summarize the results of clinical trials on health care interventions.

- United States Pharmacopeia: *www.usp.org*
- Herbnet: *www.herbnet.com*
- Herb Research Foundation: *www.herbs.org*

Nursing Process
Patient-Centered Collaborative Care

Herbal Preparations

Assessment

- Obtain baseline information about patient's use of nonconventional therapeutic agents and all prescription and OTC products used.
- Determine product name, brand, dosage, frequency, side effects, and patient's perception of effectiveness.
- Identify all prescription and OTC medications taken by patient; include dosage, frequency, side effects, and perceived effectiveness.

Nursing Diagnosis

- Enhanced readiness about therapeutic regimen related to use of herbal products

Planning

- Patient/family will verbalize understanding of herbal therapy, prescription and OTC medications, interaction between herbal therapy and prescription and OTC medications, and strategies for optimal participation in the therapeutic regimen

Nursing Interventions

- Check patient's response to herbal therapy.
- Monitor patient's response to prescription and OTC medications.
- Consult a dietitian and other specialists as necessary.
- Continue with the same brand of herbal therapy, and advise patient to notify health care provider if considering changing brands or preparations.

Patient Teaching

General

- Explain rationale for herbal therapy (see Herbal Alert 6-1).
- Advise patient to first notify health care provider before substituting any herbal product for prescription or OTC medication.
- Encourage patient to read labels and heed the recommended information displayed on the label.
- Advise patient of portion of plant used in preparation (e.g., flower or root).
- Advise patient about optimal storage conditions of the herbal remedy.

Diet

- Teach patient about foods that enhance or diminish the action of specific herbs.
- Advise patient about foods to avoid, if any, while taking herbs.

Side Effects

- Advise patient of potential side effects of herbal therapy.
- Counsel patient about symptoms that require prompt reporting to the health care provider.

Self-Administration

- Teach patient about preparation of special remedies (e.g., steeping of specific teas).

Cultural Considerations

- Assess personal beliefs of patients from different cultures.
- Modify communication to meet patient's/family's cultural needs.
- Communicate respect for patient's/family's culture.
- Evaluate effectiveness of cultural competence in interactions. If patients believe the health care provider is not sensitive to their beliefs regarding the use of herbs, they are less likely to disclose herbal regimens to future providers.
- Inquire about nutritional practices, and incorporate harmless or nonconflicting practices into the diet.
- Refrain from making prejudicial comments that may inhibit collaboration with healers.
- Do not criticize folk practices; it deters patients from seeking follow-up care and decreases trust and confidence.

Evaluation

- Evaluate the effectiveness of herbal remedies for alleviating symptoms.
- Evaluate patient's use of resources.

CRITICAL THINKING CASE STUDY

AB, a 49-year-old accountant, reports periods of feeling tired that are increasing in frequency and intensity. On her health history, she lists "no medications on a regular basis." During the nursing history, the nurse learns that AB has been taking ginseng 2 g, b.i.d., ginkgo biloba 300 mg b.i.d., and licorice root 2 mg b.i.d. for the past 6 months. Occasionally, she takes 300 mg t.i.d. of St. John's wort extract.

1. Is AB taking the recommended dose of ginseng and ginkgo biloba? If not, what modifications should the nurse suggest that she consider?
2. AB tells the nurse that she has arthritis. What modifications would be appropriate based on this new information?
3. What specific patient teaching is appropriate for AB at this time?

NCLEX STUDY QUESTIONS

1. What provisions of the Dietary Supplement Health and Education Act of 1994 are most important for the nurse to know related to patient health teaching? (Select all that apply.)
   a. Clarified marketing regulations
   b. Reclassified herbs as dietary supplements
   c. Stated that herbal products can be marketed with suggested dosages
   d. Required that package labels give quality and strength of all contents
   e. Stated that herbs can be used as drug
2. The nurse discovers that a patient has recently decided to take four herbal preparations. Which action will the nurse take first?
   a. Discuss the cost of herbal products.
   b. Instruct the patient to inform the health care provider of all products taken.
   c. Instruct the patient to stop taking all herbal products immediately.
   d. Suggest that the patient taper off use of herbal products over the next 2 weeks.
3. Labeling of herbal products is important. Which is an appropriate claim for an herbal product?
   a. "Prevents diabetes"
   b. "Helps increase blood flow to the extremities"
   c. "Cures Alzheimer's disease"
   d. "Is safe for all"
4. The nurse is reviewing a patient's current medications. Which herbal products interfere with the action of anticoagulants? (Select all that apply.)
   a. aloe
   b. feverfew
   c. ginger
   d. licorice
   e. cranberry
5. A patient has multiple prescription medications and is not able to recall which herbal product he uses for relief of migraine headaches. He notes that it is a serum antagonist and asks the nurse to assist him. What is the best response by the nurse?
   a. "Valerian"
   b. "Feverfew"
   c. "Milk thistle"
   d. "Ginkgo"
6. A patient is being followed by a cardiovascular clinic and takes garlic, which is reported to decrease cholesterol, triglycerides, blood pressure, and blood-clotting capability. Which patient statement indicates a need for further teaching? (Select all that apply.)
   a. "I can just take garlic for my heart problems."
   b. "Garlic may provide some decrease in blood pressure."
   c. "Garlic is very effective in preventing depression."
   d. "Garlic may promote healing of my incision."
   e. "Garlic will not cure impotence."
7. The nurse notes that many patients are taking herbal remedies for relief of depression and anxiety. Which herbal preparation has at least 10 pharmacologically active components for relief of depression and anxiety?
   a. St. John's wort
   b. licorice
   c. saw palmetto
   d. goldenseal
8. A patient who is pregnant asks the nurse, "What herbal products can I take?" What is the best response by the nurse?
   a. "What are you taking now?"
   b. "Taking a product at bedtime is usually not a problem."
   c. "How long have you been taking herbal products?"
   d. "Discuss this with your health care provider."
9. A patient reports taking aloe, ginkgo, and licorice on a regular basis. Which patient statement indicates a need for health teaching about potential drug interactions?
   a. "Aloe decreases the effect of my digoxin."
   b. "Ginkgo decreases the effects of my antiepileptics."
   c. "Licorice increases the effect of my digoxin."
   d. "Licorice decreases the effect of my antihypertensives."

Answers: 1, a, b, c; 2, b; 3, b; 4, b, c, d; 5, b; 6, a, c; 7, a; 8, d; 9, a.

pharmacokinetics, p. 80

A nurse who is providing care to children must make certain adaptations in assessments, treatments, and evaluations of nursing care because of the physiologic, psychological, and developmental differences inherent in this population. This is especially true in the science of pharmacology, in both the administration of medications to children and evaluation of the therapeutic and adverse effects of a medication. This chapter addresses pediatric nursing adaptations and discusses the impact of a child's growth and development on many aspects of pharmacology: pharmacokinetics, pharmacodynamics, dosing and monitoring, methods of medication administration, and nursing implications.

Pharmacology as it relates to the nursing care of infants, children, and adolescents is limited by the research available in providing protocols of recommended dosages, safe practices, key assessments, and important nursing implications. Most information available about medications is concluded from studies that use adult samples, small sample sizes, or samples with healthy children. Few studies have been conducted to determine the effectiveness of medication for target populations of children diagnosed as having applicable illnesses. Generalizing results of adult studies to pediatric populations (as in applying principles of adult pharmacology to dictate pediatric nursing practice) may result in serious errors

SAFETY: Preventing Medication Errors

Pediatric Pharmacology

- Owing to developmental factors and smaller body size, infants and young children may receive very small dosages of medications. Careful calculations, double-checking math, and checking with another registered nurse may prevent medication errors.
- Ensure that families understand the units of measurement for a medication. Confusion may occur with the discussion of metric, household, and other measurement systems.
- For safety when administering injectable medications to children, use the smallest syringe that ensures the most exact measurement of the medication.
- Use the correct medication and procedure to ensure safe dosing. Dilutions, different concentrations, and different solutions of a prescribed medication can complicate giving appropriate pediatric dosages.
- Infants and children may not be able to confirm identity, allergies, or medications. The nurse must be positive of such information before medication administration.
- Nurses must be vigilant for severe side effects or adverse reactions to medications, because information related to pediatric responses to medications is limited.
- Regulatory agencies caution that medication errors are more common in pediatric patients, warranting increased precautions in medication administration.

and ignore the impact of growth and development on pharmacology.

Research related to pediatric patients is limited because of several factors. Research risks and obtaining informed consent make it difficult to recruit a pediatric sample. Parents and guardians are reluctant to provide permission for children to participate in research studies because of the risk involved and the potentially invasive nature of data gathering. Pharmaceutical companies invest fewer resources in pediatric drug research because of the smaller market share afforded to pediatric medications. Many perceive pediatric pharmacologic research as unethical if it involves profit-margin factors. Others contend that lack of pediatric data reflects lack of due diligence, especially when medications are administered to pediatric patients without supporting research data on which to base safe practices. As a result, less is known about the effects, uses, and dosages of pediatric medications, and nurses must investigate pediatric medications carefully to provide knowledgeable nursing care for children.

Closely aligned with the conflicts that affect pediatric pharmacologic research are those associated with medication labeling and dosing instructions. Because many drugs have not undergone the clinical trials required for federal approval, they have not been approved for pediatric use. Safe use for children may be guided by small studies or the judgment of the clinician and may be based on anecdotal rather than scientific study. These conflicts have generated new legislation designed to protect pediatric patients and provide health care professionals with better information and resources.

In the United States, approximately 25% of all medications carry federally approved indications for use in children, but almost 75% of drugs marketed for adults are also prescribed for children. As a result of legislation presented in 1992 and 1994, the U.S. Food and Drug Administration (FDA) requires many medications to include known dosages, adverse effects, precautions, and effectiveness to provide health care professionals and the public some level of security when using medications. In 2003, a law known as the *Pediatric Research Equity Act* joined the Best Pharmaceuticals Act of 2002 to require drug manufacturers to study pediatric medication use and offer incentives for pediatric pharmacology research. Current research agendas reinforce the need for pediatric medication research and establishment of safe guidelines for pediatric medication dosing, administration, and evaluation. Even with increasing data, many drugs are prescribed based on off-label instructions, expert opinions, small clinical trials, or practitioners' personal experiences with the medication.

PHARMACOKINETICS

Significant differences exist in drug pharmacokinetics for pediatric patients versus adults. These distinctions stem from differences in body composition and organ maturity and appear to be more pronounced in neonates and infants but less significant in school-age and adolescent children. **Pharmacokinetics** may be defined as the study of the time course of drug absorption, distribution, metabolism, and excretion.

Absorption

The degree and rate of absorption are based on factors such as the child's age, health status, and weight, and the route of administration. As children grow and develop, the absorption of medications generally becomes more effective; therefore, less developed absorption in neonates and infants must be considered in dosage and administration. In contrast, during the adolescent years, poor nutritional habits, changes in physical maturity, and hormonal differences may cause slowing of medication absorption. Hydration status, presence of underlying disease, and gastrointestinal (GI) disorders in the child may be significant factors in the absorption of medications.

Drug absorption is initially influenced by the route of administration. For oral medication, conditions in the stomach and intestine, such as gastric acidity, gastric emptying, gastric motility, GI surface area, enzyme levels, and intestinal flora, all mediate drug absorption. Lack of maturation of the GI tract is most pronounced in infancy, making the neonatal and infancy periods those most affected by changes in absorption physiology. Gastric pH is alkaline at birth; acid production begins in the neonatal period. Gastric pH may not reach adult acidity until age 1 to 3 years. A low pH or acidic environment favors acidic drug absorption, whereas a high pH or alkaline environment favors basic drug formulations; therefore, differences in pH may hinder or enhance the absorption of medications. Gastric emptying is generally prolonged in neonates and infants but increases as the child grows. Nurses should be aware that delayed emptying in children reduces the peak serum concentrations of medications.

Varying transit times through the GI system may also hinder or enhance absorption of oral medications, depending on the usual site of chemical absorption. For this reason, feeding methods may affect infant absorption; for example, breastfed infants have faster gastric emptying than formula-fed infants. Frequent infant feedings also affect GI transit times. The more frequent the feedings, the less time the food is in contact with the gastric or intestinal lining.

Irregular peristalsis associated with immaturity or with symptoms of vomiting or diarrhea decreases the absorption time available for medications. In contrast, many pediatric medications actually cause diarrhea, which again bears on absorption rates. In younger infants and children, the GI surface area is greater than in adults, allowing for more absorptive area in the stomach and intestines. This difference in pediatric anatomy and physiology may affect the speed and effectiveness of absorption, especially in the small intestine. Immature enzyme function may also affect drug absorption; for example, low lipase levels deter the absorption of lipid-soluble medications. Microorganism colonization of the intestine, as it changes with pH and flora, creates different environments that may change medication absorption. All of these factors must be considered when assessing the effectiveness of medications administered by the oral route.

For medications administered via the subcutaneous (subQ) or intramuscular (IM) routes, absorption occurs at the tissue level. The level of peripheral perfusion and effectiveness of circulation affects the medication's ability to be absorbed. Conditions that alter perfusion (e.g., dehydration, cold temperatures, alterations in cardiac status) may impede absorption of medications in the tissues. Intravenous (IV) medications are administered directly into the bloodstream and are immediately absorbed and distributed.

Topical medications—those absorbed through the skin—may be altered by the condition of the skin tissue. Because children's skin is thinner and more porous, absorption may be enhanced. The skin surface area for children is proportionately higher than for adults such that many medications are more readily absorbed than in adults.

Distribution

The distribution of medication throughout the body of a child is affected by factors such as body fluid composition, body tissue composition, protein-binding capability, and effectiveness of various barriers to medication transport. In neonates and young infants, the human body is about 70% water. (As the child grows, this percentage decreases to 50% to 60%.) This increased body fluid proportion in the very young allows for a greater volume of fluid in which to distribute medication and a lower concentration of the drug. Until about age 2 years, the pediatric patient requires higher doses of water-soluble medications to achieve therapeutic levels. Younger patients also have higher levels of extracellular fluids, which increase the tendency for children to become dehydrated and change the distribution of water-soluble medications.

Neonates and young infants tend to have less body fat than older children. The difference means that this age group requires less fat-soluble medications than adults, because fat-soluble drugs saturate fat tissue before acting on body tissues. Less fat available for saturation creates a need for less medication.

Drugs become bound to circulating plasma proteins in the body. Only drugs that are free, or unbound, are available to cross the cell membrane and exert an effect. Infants and neonates have less albumin than older patients and fewer protein receptor sites available for binding with medication; this allows medication to be more available for use and dictates a decrease in the dosage needed in young patients to produce the same therapeutic effect. Greater quantities of circulating drugs caused by reduced plasma proteins increase the propensity for adverse or toxic reactions in infants younger than 1 year. In neonates, high bilirubin levels may pose a health risk related to the administration of medications. Bilirubin molecules may bind with plasma protein sites, making the sites unavailable to medications and allowing large amounts of drug to remain free and available for effect. If neonatal medications are prescribed, dosages must be decreased and closely monitored to both ensure therapeutic effectiveness and avoid adverse effects.

Anatomic barriers to medication distribution, such as the skin or the blood-brain barrier, must be considered when drugs are administered to pediatric patients. The skin is more absorptive in young children, as previously described, and allows rapid distribution of medication. Infants' blood-brain barriers are relatively immature, allowing medications to pass easily into nervous system tissue and increasing the likelihood for toxicity. As a child matures, both of these barriers become more impervious to medication, and dosages must be titrated accordingly.

Metabolism

The metabolism of medications depends greatly on the maturation level of the pediatric patient and varies from child to child. Metabolism is carried out primarily in the liver, with the kidneys and lungs playing a small part in the metabolic stage. For most children younger than 2 years, sustained decreases in levels of hepatic enzymes result in slower metabolism of medications. Hepatic metabolic activity is lower in neonates; infant hepatic function matures at age 1 to 2 months. This issue, as with other pharmacokinetic factors, reinforces the importance of the nurse evaluating therapeutic effects and monitoring adverse effects of medications.

Children inherently have higher metabolic rates than adults, causing metabolism to occur more rapidly. This may necessitate a higher medication requirement than for adults. For example, pain medication for children may require increased dosages or decreased durations between dosages. After oral medications are absorbed, they are metabolized in the liver. This phenomenon, called the **first-pass effect,** causes drugs administered by the oral route and absorbed via the GI tract to undergo some metabolism in the hepatocytes in the liver before they are made available to the body tissues. For select medications, when the oral route is ordered, the first-pass effect must be considered in the calculation of dosages. Some medications are administered by the rectal route to avoid the hepatic first-pass effect.

Excretion

The excretion of medications occurs in the kidneys, intestines, lungs, sweat glands, salivary glands, and mammary glands, with the kidneys providing the most elimination. Before about age 9 months, infants experience a reduction in the elimination capacity of the kidneys because of decreased renal blood flow, decreased glomerular filtration rate, and reduced renal tubular function. (At the onset of adolescence, renal tubular function is again decreased.) Because medications are excreted more slowly as a result of this decreased renal function, they can accumulate and may reach toxic levels. Water is needed for the effective excretion of medication, so patients must be evaluated for dehydration. Nurses need to carefully monitor renal function, urine flow, and medication effectiveness to evaluate the impact of medication excretion on patient status.

PHARMACODYNAMICS

Pharmacodynamics have also been used to describe differences in pediatric pharmacology. **Pharmacodynamics** refers to the mechanisms of action and effect of a drug on the body and includes the onset, peak, and duration of effect of a medication. It can also be described as the intensity and time course of therapeutic and adverse effects of medications. The variables of pharmacokinetics—absorption, distribution, metabolism, and excretion—all affect the parameters of pharmacodynamics. These processes determine the time a medication begins to function, reaches its peak, and sustains its length of action. The half-life of a medication may be different in children than in adults. Pediatric variables such as organ function, developmental factors, and administration issues affect drug pharmacodynamics and require nurses to knowledgeably evaluate the action and effectiveness of pediatric medications.

NURSING IMPLICATIONS

Pediatric Medication Dosing and Monitoring

Because of the changes in pharmacokinetics and pharmacodynamics inherent in pediatric patients, a key nursing role is to monitor the patient for therapeutic effect and adverse reactions. The processes described earlier in the chapter may be measured using plasma or serum drug levels, which indicate the amount of medication in a patient's body. Close monitoring of serum drug levels can assist in establishing appropriate dosages, schedules, and routes of administration. Monitoring can also assist in indicating when the dose is too high (toxic) or too low (not therapeutic). The therapeutic ranges established for many drug levels are based on adult studies, so it is important for the nurse to assess pediatric patients in conjunction with monitoring blood levels. Serum blood levels are not available for all medications, so patient clinical responses to medications are especially important when monitoring drug effects.

The calculation of pediatric dosages is based in part on FDA recommendations, approved protocols, research studies, and provider experience. Most medications are ordered based on the child's weight in kilograms; therefore, a "dose per unit of weight" calculation is required. In caring for children of higher weights, dosages are, at times, calculated on lean body mass to ensure an appropriate dose. Some medications, such as chemotherapies, are prescribed based on body surface area (BSA, or mg/m^2). Dosing must also consider the individual child's status, including age, organ function, health, and route of administration.

Pediatric Medication Administration

A key issue with pediatric medication administration is confirming the identification of the patient who is to receive the dose. Using the patient's identification wristband in inpatient settings is the most effective method to ensure patient identity; outpatient and other settings pose a greater challenge. Children may not be able to communicate or want to divulge their names. To ensure safe medication administration, a reliable method to identify patients for each setting must be created. Automated computerized and bar-coding systems are especially effective in ensuring safe medication administration in the pediatric population. It is the nurse's responsibility to check medication dosages and ensure that they are safe and effective.

Developmental and cognitive differences must always be considered when administering medication to children. It is important for the nurse to differentiate the child's developmental age from the chronologic age, because this difference has an impact on the child's response and responsiveness to medication. The pediatric patient's ability to understand the process, the reasons for medication, and the need to cooperate with the procedure must always figure prominently in the pediatric nurse's plan of care. The child's temperament may influence understanding and level of cooperation. Especially in pediatric nursing, the concept of **family-centered care** is essential to ensuring safe care during and after health care intervention. Teaching is directed toward family caregivers and patients commensurate with the cognitive level of the child. When possible, family members or caregivers should be solicited to assist in medication administration, taught how to administer the medications, and instructed on methods to evaluate effectiveness. These significant persons in the child's life, individuals who know the child on a day-to-day basis, are usually in the best position to evaluate the effectiveness of a medication and observe for adverse reactions. Some adverse reactions of medication in a child (e.g., ringing in ears, nausea) may be difficult to evaluate; those closest to the child may be in the best position to assess for these responses. However, parents or other family members may request not to participate in invasive procedures. This request should be respected, and parents or guardians should be encouraged to provide comfort to the child after medication is administered. Caregivers should always be supported in their caring function so that the child feels safe and secure.

Cognitive issues must be addressed such as the ability to understand (1) the reason for the medication, (2) the need for the medication despite unpleasant taste or method of administration, and (3) the need to complete all doses and courses of medication. When the family is taught about pediatric drug administration, education for the child—at a developmentally appropriate level—must also be included. Communication with the child and family must always consider level of knowledge, developmental age, cultural factors, and levels of anxiety. The nurse should use optimal interpersonal skills to ensure the best outcome in the administration of medications to pediatric patients.

The primary concerns in administering medications to infants are maintaining safety with the minimum restraint necessary, administering the correct dosage, and providing care with as much comforting as possible. Toddlers may react violently and negatively to medication administration. Simple explanations, a firm approach, and enlisting the imagination of a toddler through play may enhance success with medication administration. Preschoolers are fairly cooperative and respond well to age-appropriate explanations. Allowing some level of choice and control may facilitate success with preschool children. School-age children, although often cooperative, may fear bodily injury and should be permitted even more control, involvement in the process, and information. Age-appropriate fears related to pain, changes in body image, and injury are prevalent among older school-age and adolescent patients. The nurse should establish a positive rapport with the patient, contract with the adolescent related to the plan of care, and ensure privacy in all aspects of medication administration. Parents or guardians must be able to practice and repeat the psychomotor skills associated with medication administration.

Most pediatric medications are administered via the oral route. This route is the least invasive and easiest to use and can be used by family and home caregivers. Topical, rectal, and parenteral routes (i.e., subQ, IM, IV) are also used to deliver medications to pediatric patients for whom the oral route is contraindicated. Because of tissue differences among children, the IV route is more predictable than other routes.

Most oral medications are administered to children using an oral syringe. Oral syringes ensure more exact dosing and are relatively easy to use. Syringes may be marked to ensure correct dosages. The syringe is inserted into either side of the mouth and pointed toward the buccal mucosa. Depositing the medication too close to the front of the mouth increases the likelihood that the medication will be spit out. Pointing the syringe directly toward the back of the mouth may increase the risk for gagging or choking. Infants may suck medication from a bottle nipple into which the measured medication has been squirted from the oral syringe. Preschool and school-age children are usually able to inject oral medication into their own mouths, enhancing their sense of control over what can be an anxiety-provoking situation.

Nurses may need to crush pills or dissolve capsules in fluid for administration to pediatric patients. It is the nurse's responsibility to access information on the advisability of crushing or dissolving a medication before administration; some medications, such as time-released or enteric-coated medications, should *not* be crushed or dissolved. Some medications may be made more palatable by adding jelly, syrup, or honey (infants younger than 1 year should not be given honey because of the risk of botulism). Small volumes should be used to dilute medications so the patient is ensured the full dose. As pediatric medication research increases, more medications will be available in stable liquid pediatric forms. Until then, the nurse should work closely with pharmacy and hospital policies to ensure safe administration of oral medications to children. For children who refuse to take medication by mouth or children who require tube feeding, oral medications can be administered via nasogastric, orogastric, or gastrostomy tubes. Precautions required when giving medications via this route are similar to those implemented when administering feedings.

The administration of subQ, IM, and IV medications to children includes many of the same principles as adults, with additional considerations. Safe restraint and atraumatic care principles should be used when possible. Hockenberry defines **atraumatic care** as the delivery of therapeutic care through the implementation of interventions that "eliminate or minimize the psychological and physical distress experienced by children and their families in the health care system." Depending on developmental age, the child may have incorrect interpretations about the need for medication, believing that the medication is a punishment or a result of wrongdoing. The nurse should provide preparation for the procedure at the appropriate level for the child and involve caregivers in all aspects of care. One method to ensure atraumatic care is through the use of topical analgesics on the site before IM, subQ, or IV injections. Eutectic mixture of local anesthetics (EMLA), a topical cream, anesthetizes the site of injection if applied 1 to 2.5 hours before injection. After EMLA is applied to the injection site, the site is covered with a transparent dressing for containment. Also available are iontophoresis (Numby Stuff), a vasocoolant spray, and buffered lidocaine injections. Powdered lidocaine preparations are effective in reducing the pain and fear associated with invasive procedures in children, such as venipuncture. LET (lidocaine, epinephrine, and tetracaine) is another topical anesthetic agent used for children undergoing invasive procedures.

Based on the cognitive level of the child, distraction and other nonpharmacologic methods of pain and anxiety control can also be used to decrease the perception of pain. The use of creative imagery and hypnosis with toddlers and preschool children has been explored as a pain-management strategy. Wallace and colleagues describe the "cough trick," in which children are taught to initiate a cough during injections. This method is effective in reducing perceptions of pain in children during immunizations. Injections should *never* be given to a sleeping child with the intent to surprise the child with a quick procedure. The child may subsequently experience a lack of trust and be reluctant to sleep in the future.

IV infusion sites must be protected, especially in infants and toddlers, who do not understand the rationale or importance of maintaining the IV site. Commercial products are available to protect the IV site and maintain an intact IV infusion set. Stocking-like covers may hide the IV site from infants before they master the concept of object permanence. The patency of an IV site should be checked before each medication administration to avoid infiltration and extravasation. Any injection site on a preschooler should be covered with a bandage, preferably a decorated one, so that the child does not fear “leakage” from the area. Selection of injection and IV sites is made based on developmental variables, site of preference, and access to administration sites. The dorsogluteal site is no longer recommended for pediatric patients because of lack of development of the muscle and potential for sciatic nerve damage. The ventrogluteal or the vastus lateralis are preferred sites for pediatric IM injections. The length of the needle depends on the child’s muscle mass and subQ tissue and the site of injection. The child may prefer subQ injections in the leg or upper arm rather than in the abdomen. IV sites may be difficult to find in children. Amount of fat tissue, hydration status of the child, and ability to isolate and immobilize veins are all mitigating factors.

When administering medications to children, follow these basic principles: honesty, respect, age-appropriate teaching and explanations, attention to safety, atraumatic care, using the least amount of restraint necessary, providing positive reinforcement for age-appropriate cooperation, refraining from use of negative messages or behaviors, and upholding family-centered principles. These standards may be used throughout the pediatric life span and highlight the need for nursing intervention that is sensitive, individualized, and caring.

CONSIDERATIONS FOR THE ADOLESCENT PATIENT

Adolescent patients need individualized nursing care specific to this developmental stage. Age-oriented developmental considerations include physical changes, cognitive level and abilities, emotional factors, and impact of chronic illness.

Physically, adolescence is a highly diverse period of growth and development. Growth rates during these years may be affected by nutrition, factors within the environment, genetics and heredity, and gender. A group of adolescents of similar ages may manifest very different sizes, height-to-weight proportions, timing of secondary sex characteristics, and other indicators of physical maturity. These differences may warrant individualization of dosages based on weight or body surface area, even when the adolescent meets or exceeds the size of standard adults. For example, an adjustment may be required in the dosage of a lipid-soluble medication, because of the changes in lean-to-fat body mass, especially in young adolescent males, that coincide with physical maturation. Hormonal changes and growth spurts may necessitate changes in medication dosages; many children with chronic illnesses require dosage adjustments in the early teen years as a result of these transitions. Sleep requirements and metabolic rates may greatly increase during the teen years, along with appetite and food consumption, which may affect their scheduling of and response to medications. Although adolescents’ physical appearance and organ structure and function resemble those of adults, their bodies continue to grow and change, requiring increased vigilance in monitoring therapeutic and toxic drug levels.

The cognitive level and abilities of adolescents may pose additional considerations for the pediatric nurse. Cognitive theorists have posited that adolescents progress from concrete to abstract reasoning. Individuals who are still in the concrete operational stage may have difficulty comprehending how a medication exerts its effects on the body and the importance of meticulous dosing and administration. Teenagers may also have difficulty understanding such concepts as drug interactions, side effects, adverse reactions, and therapeutic levels. For example, the patient taking birth control pills may or may not be able to comprehend the potential implications and extra precautions needed when taking an antagonistic antibiotic during an acute infection. Patient teaching must consider the cognitive level of the individual; as adolescents learn to reason in an abstract manner, teaching may be based on more complex information. Potentially, teen perceptions of invulnerability and their difficulty in relating future consequences to current actions may dictate that the nurse adapt teaching to address specific adolescent thought processes. Newer research into the teenage brain and the ongoing development of decision-making, social, and reasoning skills may inform how nurses assess and intervene with the pediatric patient. An adolescent who is told that an insulin injection schedule must be adhered to in order to avoid long-term complications may not understand the rationales for treatment if he or she is only substantiated by abstract, future-oriented risks. The same patient may find the relationship between using insulin to maintain normoglycemia and the ability to participate in sports more immediate and relevant.

Emotional development of the teenager also occurs on an individual basis. The teen years are characterized by sensation seeking, risk taking, questioning, formation of identity, and increasing influences exerted by peer groups. The nurse should assess for high-risk behaviors, including use of alcohol, tobacco, and recreational drugs, to avoid potential drug interactions. Other issues, including sexual practices and stressful family and social situations, may affect the patient’s response to medications. Nurses must be respectful of the emotional needs of adolescence while attending to the mental health issues that may surface during these years. A comprehensive history must be solicited from teenage patients to ensure appropriate medication administration.

The nurse is often positioned in a key role for establishing a productive working relationship with the patient and providing the patient with appropriate levels of privacy. Allowing the adolescent to verbalize concerns about the medication and its regimen may offer opportunities for clarifying misconceptions and teaching new concepts. The nurse must also be conscious of the need to exercise care in offering confidentiality in the event that information needs to be divulged to other health care providers, parents, or caregivers to ensure patient safety.

As adolescents attain greater levels of independence from their parents, self-care behaviors increase. The nurse should assess the patient's abilities to self-administer medication and self-monitor therapeutic and adverse reactions. Teenagers spending less time with parents and caregivers may need increased instruction about their medication regimen and the key observations that are needed. Although teenagers frequently display "breaking away" behaviors in response to parental bonds, they often continue to use parent or caregiver medication habits as models for their own medication behaviors.

For the child with a chronic illness, issues may change in the teen years. Engaging peers in the medication plan of care, allowing the teenager to make safe choices and have flexibility within that plan, setting up mutual medication contracts, and permitting the patient to design his or her own adult-monitored medication regimen may facilitate adherence. The family's key role in management of chronic illness changes during adolescence. Such issues as rebellion against rules, refusal to take medications, and participation in high-risk behaviors may need to be dealt with. The nurse can facilitate required adaptations and support both the patient and the family during these times.

Teenagers who need to receive medications may require assistance with decision making, organization of a medication schedule, and understanding of the key physical, cognitive, and emotional changes characteristic of this stage. Nurses' levels of knowledge and caring support may offer a great contribution to adolescent patients and their families.

NURSING PROCESS: PATIENT-CENTERED COLLABORATIVE CARE

In working with pediatric patients, key developmental differences must be considered when administering and monitoring medications. The nursing process provides the framework to guide nursing practice in administering medications, planning and evaluating nursing care, providing patient and family teaching, and incorporating the family into all aspects of treatment.

Family and patient teaching is a key role for the nurse. Issues such as indications for the medication, the side effects, the dose, how to measure the dose, how to administer the dose, the therapeutic effect, adverse effects to monitor for, the duration, and the frequency are all important information needed by the family or caregiver. Specifics such as the need for refrigeration, the need to shake the medicine, the difference between household and prescriptive measurements, and other issues should be addressed to ensure patient safety. Adherence to the medication regimen is of paramount importance with children and families; providing written instructions or a medication calendar may facilitate this through concrete reminders.

Nurses should also be aware of the tendency for parents to treat infants and children with over-the-counter (OTC) analgesics. Parents may provide frequent analgesia to their children and may be largely unaware of the potential for misuse and overuse in the pediatric population. Additional concern has arisen regarding the inappropriate use of OTC cough and cold remedies with children. Deaths and significant illness have been attributed to lack of label recommendations, misuse of adult medications, poor medication instructions, and overdose, warranting rigid restrictions on their use in the pediatric population.

HERBAL ALERT 7-1

Pediatric

Herbal preparations are generally not recommended for use in children.

Nursing Process
Patient-Centered Collaborative Care

Pediatrics

Assessment

- Record the age, weight, and height of the child. Drug calculations are based on these three factors.
- Assess the allergy history of the child, and determine family allergy history.
- Assess developmental age, health status, nutritional status, and hydration status.
- Assess history of drug use (prescriptions, OTC, herbal).
- Assess family's understanding and child's cognitive level.

Nursing Diagnoses

- Delayed growth and development related to physiologic, congenital, or environmental factors
- Risk for ineffective peripheral tissue perfusion related to decreased fluid volume, decreased cardiac output, or developmental physiologic differences
- Impaired urinary elimination related to decreased fluid volume, renal immaturity, congenital anomalies, or decreased renal perfusion
- Deficient knowledge related to new parenting role, lack of exposure to children and adolescents, language barrier, cognitive discrepancy, or new diagnosis
- Risk for injury related to developmental, cognitive, and environmental factors
- Ineffective health maintenance related to cognitive, experiential, environmental, and social factors
- Readiness for enhanced knowledge related to parenting and progression through child's developmental stages

Planning

- The child will receive drug dosage based on age, weight, and height. Most drug calculations for children are related to weight in kilograms or BSA.
- Consider developmental factors and elements of family-centered care in all medication administration.

Nursing Interventions

- Use appropriate drug references to obtain the drug parameters or ranges, side effects, and contraindications for use when administering drugs to children.
- Monitor infants and young children closely for side effects of drugs because of their developmental differences. Because infants and young children have limited communication skills, changes in their usual behavior pattern may indicate side effects.
- Communicate with the health care provider about drug dosages that are questionable for infants and young children because of developmental differences. Calculate the child's drug dose according to weight in kilograms or BSA.

Patient Teaching

- Teaching patients and families about medications, dosages, therapeutic effects, side effects, and precautions is key in the pediatric population, especially with nonverbal, young, or at-risk children.
- Advise the responsible family member not to give OTC drugs to children without first consulting the health care provider.
- Advise the family member to immediately report side effects of the medication to the health care provider.
- Advise mothers who are breastfeeding their newborn or infant to consult a health care provider when taking any medication, because a portion of most drugs is excreted in breast milk.
- Nurses must be aware that parents and families frequently believe that all pediatric infections are treated with an antibiotic. The nurse plays a key role in raising awareness about avoiding the overuse of antibiotics for viral infections and allergic responses to avoid the development of resistant organisms.
- Advise the family member to keep medications out of the reach of children.
- Suggest that the family member use child-resistant medication containers.

Cultural Considerations

- Consider cultural differences when providing care and teaching about medications to children and families. These may include areas such as eye contact, personal space, time orientation, parenting roles/beliefs, value of children, and communication styles.
- Some cultures may adhere to folk and other health practices, including using herbal preparations for children. Nurses should ensure that families understand the contraindications and precautions associated with use of herbal products in children.
- When soliciting adolescent health histories, consider issues related to sexual practices, risk behaviors, recreational drug use, and other issues that may affect medication administration and safety. Provide privacy when asking sensitive questions.

Evaluation

- Evaluate the family member's knowledge about the drug, the dosage, the schedule for administration, and the side effects.
- Evaluate the child's physiologic and psychological response to the drug regimen.
- Evaluate the therapeutic and adverse effects of the medication(s).

CRITICAL THINKING CASE STUDY

A 6-month-old child enters the emergency department with a 3-day history of vomiting with diarrhea. The patient is started on IV hydration. A stool culture indicates a bacterial infection in the GI tract.

1. How might the diagnosis of dehydration affect the pharmacokinetics of IV antibiotic therapy?
2. What physiologic factors make young babies prone to dehydration?
3. What components of family-centered care are critical for infants and their families when ill or hospitalized?

NCLEX STUDY QUESTIONS

1. An 8-month-old patient is discharged from the hospital with a plan of care to receive IM injections each day. The parents have been taught how to administer IM injections. Which statement by the parents indicates a need for further teaching?
   - a. "I should administer the injection in the upper, outer quadrant of her buttocks."
   - b. "IM injections are safe for infants and children if administered correctly."
   - c. "When I give my daughter this injection, the safest place for insertion is the thigh."
   - d. "I need someone to assist me and hold my daughter while I give the injection."
2. A 4-year-old patient is discharged on an oral liquid drug suspension of 4 mL per dose. Which device will the nurse recommend to ensure the highest level of accuracy in home administration of the medication?
   - a. Measuring spoon
   - b. Graduated medicine cup
   - c. Household teaspoon
   - d. Oral syringe
3. A child is ordered to receive naloxone (Narcan) IV, STAT. The child's weight is 20 kg. The recommended child's dosage is 0.01 mg/kg. Naloxone is available in a 400 mcg/mL solution. How much medication will the nurse plan to administer?
4. A child is ordered to receive 3 mg/kg of medication. The child weighs 88 pounds. The medication is available in a 15 mg/mL elixir. How much medication will the patient receive?
5. The nurse understands the differences between drug excretion in children and that in adults. With this knowledge, what does the nurse consider when administering medications to children?
   - a. Most children need a higher dose of medication, so the nurse will contact the physician for an increase in the ordered dose.
   - b. Children excrete drugs rapidly, so the nurse must assess carefully for therapeutic effects of the medication.
   - c. The most important assessment is to evaluate for drug accumulation, because the excretion of drugs in children is slower.
   - d. Excretion of most drugs is the same in children as in adults, but assessments are important to avoid side effects.
6. A parent is learning to administer medication to a school-age child. Which strategy will the nurse teach the parent to achieve cooperation in a child of this age?
   - a. Enlisting physical restraint
   - b. Establishing medication contracts
   - c. Providing age-appropriate explanations
   - d. Tolerating violent reactions
7. The nurse is caring for a neonate with lower-than-normal albumin levels. The nurse is ordered to administer a medication that is highly protein bound. The nurse knows that what must occur in response to these factors?
   - a. The dose must be doubled to compensate for low albumin levels.
   - b. The dose must be decreased because of increased unbound, active medication.
   - c. Highly protein-bound drugs must be contraindicated.
   - d. The nurse must further clarify the medication order before administration.
8. A nurse caring for a child with developmental delay prepares to teach the patient about prescribed medications. Which actions are essential in ensuring patient safety? (Select all that apply.)
   - a. Assess the child's developmental age.
   - b. Assess for side effects the same as those experienced by adults.
   - c. Consider the actions and uses of the medication.
   - d. Focus on the child's chronological age.
   - e. Involve the family in teaching sessions.
9. A 2-year-old patient is to receive a topical medication. The nurse considers which factor when administering this medication?
   - a. Children's skin is less vascular, slowing absorption.
   - b. Decreased hair follicles enhance absorption.
   - c. Medications are absorbed slower due to less BSA than adults.
   - d. Thinner skin in children allows for rapid absorption.

OBJECTIVES

- Explain the physiologic changes of the aging process that have a major effect on drug therapy.
- Explain the pharmacokinetics and pharmacodynamics of the older adult that relate to drug dosing.
- Differentiate the effects of two drug categories on the older adult.
- Discuss reasons for noncompliance to drug regimen by the older adult.
- Describe nursing implications related to drug therapy in the older adult.

KEY TERMS

adherence, p. 94
nonadherence, p. 93
older adult, p. 88
polypharmacy, p. 89

In coming years, nurses will care for increasing numbers of older adults, who will represent the "core business" of health care. Geriatric pharmacology for the **older adult** requires special attention to the age-related factors of drug absorption, distribution, metabolism, and excretion. Drug dosages are adjusted according to the older adult's weight, adipose tissue, laboratory results (e.g., serum protein, electrolytes, liver enzymes, blood urea nitrogen [BUN], creatinine clearance), and current health problems. Modifications in drug therapy for the older adult are frequently required. Because of declining organ functioning in older adults, the effects of drug therapy must be closely monitored to prevent adverse reactions to drugs and possible drug toxicity.

Approximately 85% of adults older than 65 years take medications. By 2030, it is expected that the number of older adults will be nearly twice the number in 2000. Women 65 years old presently outnumber men of that age by 134 to 100; in the 75-year-old age group, there are 100 women to 55 men. A fast-growing population is those age 85 years and older, and their use of drug therapy will likely continue to grow.

Older adults take pain, sleep, and laxative over-the-counter (OTC) drugs more frequently than younger populations. At the time of hospital admission, only about 15% of patients older than 65 years are not taking any medications (prescribed or self-medicated). During hospitalization, older adults take an average of three to five drugs. In nursing homes, 33% of patients receive 6 to 12 drugs daily.

The adverse reactions and drug interactions that occur in the older adult are three to seven times greater than those for middle-aged and young adults. Older adults consume numerous drugs because of chronic and multiple illnesses; therefore, they are susceptible to adverse reactions and interactions. Additional problems that can cause adverse reactions from drugs include self-medicating with OTC drugs, taking drugs prescribed for other health problems, taking drugs ordered by several different health care providers, overdosing when symptoms do not subside, taking new drugs to treat the side effects of other drugs, using drugs that were prescribed for another person, and, of course, the ongoing physiologic aging process. Intentional noncompliance (possibly related to drug costs or side effects) and unintentional noncompliance (possibly related to complicated, confusing drug regimens or impaired mental status) must be assessed, as should alcohol use or abuse and its interactions with medications.

Drug toxicity may develop in the older adult for drug doses that are within the therapeutic range for the younger adult. These therapeutic drug ranges are usually safe for young and middle-aged adults but are not always within safe range for older adults. It has been suggested that the drug dose for older adults should initially be prescribed at a low to low-average therapeutic range and then gradually increased according to tolerance and lack of adverse reactions; *start low and go slow* is an important concept. This approach prevents a toxic reaction to the drug in older adults. Older adults who are at risk for problems with medication administration frequently have common characteristics such as lack of coordinated care, recent discharge from the hospital, self-treatment, multiple diagnoses, sensory and physical changes associated with aging, multiple health care providers, and cognitive impairment.

PHYSIOLOGIC CHANGES

The physiologic changes associated with the aging process have a major effect on drug therapy. Table 8-1 describes the physiologic changes that occur in the gastrointestinal (GI), cardiac and circulatory, hepatic, and renal systems of the older adult and how these changes can affect pharmacologic response to drug therapy.

TABLE 8-1 **PHYSIOLOGIC CHANGES IN THE OLDER ADULT**

SYSTEM	PHYSIOLOGIC CHANGE	EFFECT ON DRUG ADMINISTRATION
Gastrointestinal	↑ pH (alkaline) gastric secretions ↓ peristalsis with delayed intestinal emptying time ↓ motility ↓ first-pass effect	Slower absorption of oral drugs
Cardiac and circulatory	↓ cardiac output ↓ blood flow	Impaired circulation can delay transportation of drugs to the tissues
Hepatic	↓ enzyme function ↓ blood flow	Drugs metabolized more slowly and less completely
Renal	↓ blood flow ↓ functioning nephrons (kidney cells) ↓ glomerular filtration rate	Drugs excreted less completely

↓, decrease; ↑ increase.

POLYPHARMACY

Polypharmacy (administration of many drugs together) is more common in older adults because of the use of (1) multiple health care providers, (2) herbal therapy, (3) OTC drugs, and (4) discontinued prescription drugs. Polypharmacy can cause confusion, falls, malnutrition, renal and liver dysfunction, and nonadherence. The nurse should coordinate the health care of older adults, including drug therapy, to avoid duplication of drugs from various health care providers and misuse of OTC and herbal supplements. For example, an older patient may take a prescribed drug, ranitidine (Zantac), with an OTC drug, famotidine (Pepcid AC), for GI discomfort; this drug combination causes duplication to occur. Some older adults do not think herbal drugs are actually drugs that could cause adverse reactions when taken with other prescription or OTC drugs. Older adults should be encouraged to use one pharmacy and give the pharmacist a list of all drugs they take, both prescribed and OTC. Pharmacists conduct clinical reviews of medications that focus primarily on drug interactions.

PHARMACOKINETICS

Parameters of pharmacokinetics for the older adult are described in Table 8-2.

Absorption

Drug absorption from the GI tract is slowed in the older adult because of decreases in both blood flow and GI motility. In this age group, acidic drugs are poorly absorbed because of increased alkaline gastric secretions, but enteric-coated tablets dissolved in alkaline fluid can break down more rapidly. Drugs remain in the GI tract longer because there is a decrease in gastric motility, causing delayed onset. Iron and calcium tablets may not be absorbed as readily; generally, however, the amount of an oral dose that is absorbed is not affected by age.

Distribution

Older adults have a loss of protein-binding sites for drugs, which causes increased circulation of free drug and increased chance for adverse drug reaction. During the aging process,

TABLE 8-2 **PHARMACOKINETICS IN GERIATRIC PHARMACOLOGY**

PHASES	BODY EFFECTS AND POSSIBLE DRUG RESPONSES
Absorption	Decrease in gastric acidity (increased gastric pH) alters absorption of weak acid drugs such as aspirin. Decrease in blood flow to the GI tract (up to 40% to 50% less) may be caused by decrease in cardiac output. Because of reduced blood flow, absorption is slowed but not decreased. Reduction in GI motility rate (peristalsis) may delay onset of action. Reduction in gastric emptying time occurs.
Distribution	Because of a decrease in body water, water-soluble drugs are more concentrated. Increase in fat-to-water ratio in older adult; fat-soluble drugs are stored and likely to have decreased effect. Decrease in circulating serum protein. Acidic drugs (e.g., nonsteroidal antiinflammatory drugs [NSAIDs], aspirin, benzodiazepines, phenytoin, and warfarin) bind to albumin; basic drugs (e.g., beta-adrenergic blockers, tricyclic antidepressants, lidocaine) bind to alpha$_1$ acid glycoprotein. With fewer protein-binding sites, there is more free drug available to body tissue at receptor sites. Drugs with a high affinity for protein (>90%) compete for protein-binding sites with other drugs. Drug interactions result because of lack of protein sites and increase in free drugs.
Metabolism	Decrease in hepatic enzyme production, hepatic blood flow, and total liver function. These decreases cause a reduction in drug metabolism. With reduction in metabolic rate, t½ of drugs increases; drug accumulation can result and lead to toxicity.
Excretion	Decrease in renal blood flow and decrease in glomerular filtration rate. A decrease in renal function results in a decrease in drug excretion; thus drug accumulation results. Drug toxicity should be assessed continually while the patient takes the drug.

GI, Gastrointestinal; *t½*, half-life.

there is a loss of body water, and water-soluble drugs become more concentrated in the body. Because of an increase in body fat in the older adult, a greater amount of lipid-soluble drugs is absorbed into fat, causing a decrease in desired drug effects.

Metabolism or Biotransformation

Hepatic blood flow in the older adult may be decreased by 40% to 45%, and aging causes a decrease in liver size. Drug clearance by hepatic metabolism is affected more in older male adults than in older female adults.

Liver dysfunction, caused by the aging process, decreases enzyme function, which decreases the liver's ability to metabolize and detoxify drugs, thereby increasing the risk of drug toxicity.

The liver and kidneys are the major organs responsible for drug clearance from the body. *Biotransformation* refers to drug metabolism that occurs in the liver and contributes to drug clearance. Biotransformation during hepatic metabolism can occur either in phase I by oxidation reaction or in phase II by conjugation reaction. Hepatic microsomal enzymes are responsible for phase I, oxidation reaction. Hepatic microsomal oxidation can be impaired by the aging process, liver diseases (e.g., cirrhosis, hepatitis), and drugs that reduce oxidation capability. Drug clearance by the liver is then reduced. An example of a drug that undergoes a phase I biotransformation oxidation reaction is diazepam (Valium). Diazepam is biotransformed to its active metabolite, desmethyldiazepam. In the older adult, the plasma-serum diazepam level would remain high because of an impaired phase I oxidation reaction. Other drugs that are biotransformed by phase I include barbiturates, codeine, ibuprofen, phenytoin, meperidine, lidocaine, certain benzodiazepines (alprazolam [Xanax], midazolam [Versed]), and warfarin (Coumadin).

Phase II of biotransformation involves the conjugation or attachment of the drug to an inactive state. Hepatic conjugation is usually not influenced by older age, liver diseases, or drug interaction, so the drug is inactivated and excreted in the urine. Examples of drugs that are biotransformed or metabolized by phase II are aspirin, acetaminophen, certain benzodiazepines (lorazepam [Ativan], oxazepam [Serax], temazepam [Restoril]), procainamide, and sulfanilamide. The benzodiazepines lorazepam, oxazepam, and temazepam that undergo conjugation reaction do not have active metabolites. The drug metabolic process, phase I or II, for drug clearance for the older adult patient is an important consideration with drug selection.

To assess liver function, liver enzymes must be checked. Elevated levels indicate possible liver dysfunction. The older adult could have normal liver function test (LFT) results and still have impaired hepatic microsomal enzyme-drug oxidation reactions.

Excretion

Cardiac output and blood flow throughout the circulatory system are decreased in older adults, affecting blood flow to the liver and kidneys. After age 65 years, nephron function may be decreased by 35%; after age 70 years, blood flow to the kidneys may be decreased by 40%.

Kidney function is assessed by monitoring urine output, laboratory values of BUN and serum creatinine (Cr), and creatinine clearance (CLcr or CrCl) (estimated). Creatinine clearance is an indicator of glomerular filtration rate (GFR). To evaluate renal function based on serum creatinine alone may not be accurate for the older adult because of the decrease in muscle mass that can cause a decrease in serum creatinine. Creatinine, a by-product of muscle catabolism, is primarily excreted by the kidneys. With older adult patients, serum creatinine may be within normal values because of a lack of muscle mass, but there still could be a decrease in renal function.

The 24-hour creatinine clearance test and the serum creatinine level should be used to evaluate renal function. If a 24-hour creatinine clearance test is not feasible, the following formulas can be used to estimate creatinine clearance:

$$\text{CLcr (men)} = (140 - \text{age}) \times \text{kg}/72 \times \text{serum Cr level} = \text{mL/min}$$

$$\text{CLcr (women)} = \text{value of men} \times 0.85 = \text{mL/min}$$

The normal creatinine clearance value for an adult is 80 to 130 mL/min.

With liver and kidney dysfunction, the efficacy of a drug dose is usually increased. Multiple drug use may intensify drug effect in the older adult. When the efficiency of the hepatic and renal systems is reduced, the half-life of the drug is prolonged and drug toxicity is probable.

Adverse Reactions

Factors contributing to adverse reactions in the older adult include a loss of protein-binding sites, which increases the amount of free circulating drug; a decline in hepatic first-pass metabolism; and a prolonged half-life of the drug because of decreased liver and kidney function. Because of these factors, the time interval between doses of a drug may need to be increased, or the dose decreased, for the older adult patient.

PHARMACODYNAMICS

Because there is a lack of affinity to receptor sites throughout the body in the older adult, the pharmacodynamic response may be altered. The older adult could be more or less sensitive to drug action because of age-related changes in the central nervous system (CNS), changes in the number of drug receptors, and changes in the affinity of receptors to drugs. Frequently, the drug dose must be lowered. Consideration of changes in organ function is important in drug dosing.

In the older adult patient, the compensatory response to physiologic changes is decreased. When a drug with vasodilator properties is administered and the sympathetic feedback does not occur quickly, orthostatic hypotension (i.e., rapid decrease in blood pressure when changing position quickly) could result. In the younger adult, the sympathetic response of vasoconstriction works to avert a severe hypotensive effect.

EFFECTS OF SELECTED DRUG GROUPS ON OLDER ADULTS

Hypnotics, diuretics and antihypertensives, cardiac glycosides, anticoagulants, antibacterials (antibiotics), GI drugs (antiulcers, laxatives), antidepressants, and opioid analgesics are drug categories for which drug effects on the older adult are possible. The number of drugs taken, drug interactions (see Chapter 4), and physical health of the older adult (cardiac, renal, and hepatic function) are factors associated with drug effects in the older adult population. Drug selection is extremely important. Drugs with a shorter half-life are less likely to cause problems as a result of drug accumulation than drugs with a long half-life. If severe side effects occur, the drug with a shorter half-life is eliminated more quickly than the drug with a longer half-life.

Evaluation of hepatic and renal function is imperative, especially if the older adult takes multiple drugs. When side effects and adverse reactions occur, prescription and nonprescription drugs should be assessed (Herbal Alert 8-1).

HERBAL ALERT 8-1

Older Adults

Advise patients to consult with the health care provider before starting herbal products. Common herbal preparations (e.g., ginger, gingko, ginseng, garlic) interact with many drugs (e.g., anticoagulants) that older adult patients take to treat chronic health disorders.

Hypnotics

Insomnia (having difficulty in falling asleep, frequently awakening during the night, or awakening early in the morning with difficulty falling back to sleep) is a frequent problem in the older adult population. Sedatives and hypnotics are the second most common group of drugs prescribed or taken OTC. Types of hypnotics differ according to the cause of insomnia. Five benzodiazepine hypnotics (flurazepam, quazepam, temazepam, triazolam, and estazolam) have been approved by the U.S. Food and Drug Administration (FDA) as hypnotics to control insomnia. For the older patient, low doses of benzodiazepines with short or intermediate half-lives are usually prescribed. Short-term therapy is suggested. Usually benzodiazepines are prescribed at higher doses for sedative and hypnotic effects and at lower doses for antianxiety effects. About 35% of older adults take a hypnotic.

Flurazepam HCl (Dalmane), the first benzodiazepine hypnotic, was introduced in 1970. It has three metabolites and is considered to be both a short- and long-acting hypnotic. Its principal metabolite is desalkylflurazepam, which is long-acting, has a long half-life, and is slowly eliminated. This drug is not suggested for persons older than 65 years. Drug hangover is a problem. Quazepam (Doral) has effects similar to flurazepam. It is a precursor of desalkylflurazepam and has a prolonged half-life.

Temazepam (Restoril) was introduced in 1981. Because it is biotransformed in the liver by conjugation and not by oxidation, it is prescribed frequently for the older adult patient. Temazepam's principal metabolite, glucuronide, is conjugated with no pharmacologic effects and excreted in the urine. Temazepam is slowly absorbed, so it should be taken 1 to 2 hours before bedtime. It is classified as an intermediate-acting benzodiazepine. Food delays its action. Temazepam is more effective for frequent awakenings during the night than for problems falling asleep.

Triazolam (Halcion) is an intermediate-acting benzodiazepine. It has a short half-life and at low doses (0.0625 to 0.125 mg) is considered safe for the older adult. It is metabolized by hepatic microsomal oxidation, although the drug doses differ from oxidized benzodiazepines. Triazolam helps with problems falling asleep, and it also decreases frequent awakenings during the night. To avoid rebound insomnia when the drug is discontinued, doses should be tapered rather than abruptly stopped.

Estazolam is an intermediate- to long-acting drug. It is metabolized in the liver to two metabolites that are not highly potent.

The benzodiazepines lorazepam and oxazepam can be used for insomnia. These agents have an intermediate half-life and should be taken 1 hour before bedtime. Other benzodiazepines are more effective as anxiolytics (antianxiety drugs) than as hypnotics.

Diuretics and Antihypertensives

Diuretics are frequently prescribed for treatment of hypertension or heart failure. For the older adult, the dose is usually reduced because of dose-related side effects. Hydrochlorothiazide (HydroDIURIL) is generally prescribed in low doses of 12.5 mg/day. Higher doses of 25 to 50 mg/day with chronic use can cause electrolyte imbalances (e.g., hypokalemia, hyponatremia, hypomagnesemia, hypercalcemia), hyperglycemia, hyperuricemia, and hypercholesterolemia.

Many older adult patients are hypertensive (blood pressure >140/90 mm Hg). Nonpharmacologic methods to reduce blood pressure such as exercise, reduction of salt and alcohol intake, and adequate rest are suggested. These actions can reduce the systolic and diastolic pressure by 8 to 10 mm Hg. Diuretics, beta-adrenergic blockers or antagonists, calcium channel blockers, angiotensin-converting enzyme (ACE) inhibitors, angiotensin II receptor antagonists (A-II blockers), and centrally acting alpha$_2$ agonists are used as antihypertensive drugs. Calcium blockers, angiotensin-converting inhibitors, and A-II blockers are frequently the agents of choice because of their low incidence of electrolyte imbalance and CNS side effects (see Chapter 44). Usually antihypertensive dosing for older adults begins with reduced doses that are gradually increased according to need, tolerance, and adverse reactions. Because of adverse reactions such as orthostatic hypotension, alpha$_1$ blockers or antagonists (prazosin, terazosin) and centrally acting alpha$_2$ agonists (methyldopa, clonidine, guanabenz, guanfacine) are infrequently prescribed for older adults.

Cardiac Glycosides

Digoxin (Lanoxin) is commonly prescribed for older adults; however, long-term use of the drug should be carefully monitored because of its narrow therapeutic range (0.5 to 2 ng/mL) and the possibility of digitalis toxicity. Digoxin is given for left ventricular heart failure, chronic atrial fibrillation, and atrial tachycardia. Its half-life is doubled (70 hours) in patients older than 80 years. Most of the digoxin is eliminated by the kidneys, so a decline in kidney function (decreased GFR) could cause digoxin accumulation. With close monitoring of serum digoxin levels, creatinine clearance tests, and vital signs (pulse should be >60 beats per minute), digoxin is considered safe for the older adult.

Anticoagulants

Bleeding may occur with chronic use of anticoagulants in older adult patients. Warfarin (Coumadin) is 99% protein bound; with a decrease in serum albumin, which is common among older adults, there is an increase in free, unbound circulating warfarin and a potential risk for bleeding. Older adult patients should have their prothrombin time (PT) or international normalized ratio (INR) checked periodically, and the nurse should check for signs of bleeding. Older adults are more at risk for falls and injury that can cause bleeding complications from drug interactions affecting Coumadin levels.

Antibacterials

Penicillins, cephalosporins, tetracyclines, and sulfonamides are normally considered safe for the older adult. If renal drug clearance is decreased and the drug has a prolonged half-life, the drug dose should be reduced. Aminoglycosides, fluoroquinolones (quinolones), and vancomycin are excreted in the urine. These drug agents are not frequently prescribed for patients older than 75 years, and, if they are prescribed, the drug dose is usually reduced.

Gastrointestinal Drugs

Histamine (H$_2$) blockers and sucralfate are safer drugs than other antiulcer agents for the treatment of peptic ulcers. Cimetidine (Tagamet) was the first histamine blocker or antagonist and is not suggested for the older adult because of its side effects and multiple potential drug interactions. Ranitidine (Zantac), famotidine (Pepcid), and nizatidine (Axid) may be prescribed for older adult patients instead of cimetidine.

Laxatives are frequently taken by older adults. In long-term facilities such as nursing homes, 75% of residents take laxatives on a daily basis. Fluid and electrolyte imbalances may occur with excessive use. Increased GI motility with laxative use could decrease absorption of other drugs. Nonpharmacologic measures such as increasing fluid intake, consuming high-fiber foods, and exercising should be encouraged.

Antidepressants

An antidepressant drug dose for older adults is normally 30% to 50% of the dose for young and middle-aged adults. Drug dose should be gradually increased according to the patient's tolerance and the desired therapeutic effect. Close monitoring for possible adverse reactions is important.

Although tricyclic antidepressants are generally effective in the older adult population, their anticholinergic properties can cause side effects such as dry mouth, tachycardia, constipation, and urinary retention. Tricyclic antidepressants can also contribute to narrow-angle glaucoma. Fluoxetine (Prozac), a bicyclic antidepressant, has fewer side effects than the tricyclic antidepressants, and the side effects are mostly dose-related. Monoamine oxidase inhibitors (MAOIs) are not often prescribed for older adults because of adverse reactions such as drug-food interactions that could result in hypertensive crisis and severe orthostatic hypotension. (Refer to Chapter 28 for a discussion of antidepressants.)

Opioid Analgesics

Opioids can cause dose-related adverse reactions when taken by the older adult. Hypotension and respiratory depression may result from opioid use, so close monitoring of vital signs is essential when providing nursing care and support to the older adult patient on opioid analgesics. Constipation is another side effect; patients taking these medications must also take stool softeners.

Table 8-3 presents a list of drugs not generally recommended for use in older adult patients.

ADHERENCE AND NONADHERENCE

Nonadherence with a drug regimen can be a problem in all patient age groups, but it is especially troublesome in older adult patients. Frequently the older adult fails to ask questions during interactions with health care providers; therefore the drug regimen may not be fully understood or precisely followed. Nonadherence can cause underdosing or overdosing that could be harmful to the patient's health. Table 8-4 lists barriers to effective medication use by older adults.

SAFETY: Preventing Medication Errors

Do not confuse …

- **Celebrex**, a COX-2 inhibitor, with **Celexa**, an SSRI
- **Ditropan**, an antispasmodic/anticholinergic, with **Diflucan**, an antifungal
- **Digoxin** (Lanoxin), a cardiac glycoside used to treat heart failure, with **levothyroxine**, synthetic T_4 used to treat hypothyroidism
- **Xanax**, a benzodiazepine used to treat panic disorder, with **Zantac**

TABLE 8-3 DRUGS NOT GENERALLY RECOMMENDED FOR USE IN OLDER ADULT PATIENTS

DRUGS	DRAWBACKS	ALTERNATIVES
Analgesics		
ketorolac (Toradol and others)	Serious GI toxicity	
meperidine (Demerol and others)	Confusion, convulsions	Morphine preferred
Antidepressants, Tricyclic		
amitriptyline (Elavil)	Anticholinergic effects (constipation, urinary retention, blurred vision, confusion), orthostatic hypotension, sedation, and cardiac arrhythmias	Selective serotonin reuptake inhibitors (SSRIs) other than daily fluoxetine; other antidepressants preferred
doxepin (Sinequan)		
Antihistamines, First-Generation		
chlorpheniramine (Chlor-Trimeton)	Anticholinergic effects; some such as diphenhydramine and promethazine are highly sedating	Second-generation antihistamines such as fexofenadine (Allegra) or loratadine (Claritin) preferred
diphenhydramine (Benadryl)		
hydroxyzine (Vistaril)		
promethazine (Phenergan)		
Antispasmodics		
belladonna alkaloids (Donnatal)	Anticholinergic effects	
dicyclomine (Bentyl)		
hyoscyamine (Levsin)		
propantheline (Pro-Banthine)		
Muscle Relaxants		
carisoprodol (Soma)	Anticholinergic effects, sedation, limited effectiveness at tolerated doses	
cyclobenzaprine (Flexeril)		
methocarbamol (Robaxin)		
metaxalone (Skelaxin)		
Sedatives		
Barbiturates	Sedation, addiction	
benzodiazepines, long-acting	Prolonged sedation	Low doses of shorter-acting benzodiazepines such as lorazepam (Ativan) preferred
chlordiazepoxide (Librium)	Sedation, addiction	
diazepam (Valium)		
Other		
cimetidine (Tagamet)	Confusion, many drug interactions	Other H_2 agonists preferred
nitrofurantoin (Macrobid)	Limited efficacy in renal impairment	Other antibiotics preferred
trimethobenzamide (Tigan)	Extrapyramidal side effects, limited effectiveness	

TABLE 8-4 BARRIERS TO EFFECTIVE MEDICATION USE BY OLDER ADULTS

CAUSES	NURSING ACTIONS
Taking too many medications at different times	Develop a chart indicating times to take drugs. Provide space to place a mark for each drug taken. Coordinate medication regimen with activities of daily living (e.g., meals) and events. Use an organizer container (daily or weekly). Have the patient bring all medications, including over-the-counter drugs and herbal, vitamin, and mineral supplements, to all health appointments.
Failure to understand purpose or reason for drug	Explain the purpose, drug action, and importance of the medication. Provide time for questions and reinforcement. Reinforce with written information.
Impaired memory	Encourage family members or friends to monitor the patient's drug regimen.
Decreased mobility and dexterity	Advise family members or friends to have drugs and water or other fluid accessible. Assist older adults as needed.
Visual and hearing disturbances	Suggest eye and ear examinations (glasses or hearing aids).
High cost of prescriptions	Contact the social services department of your institution; contact "compassionate care programs" as appropriate.
Childproof drug bottles	Suggest that the patient request non-childproof bottle caps.
Side effects or adverse reactions from the drug	Educate the patient and family about side effects to report to the health care provider.

Nonadherence can lead to adverse reactions, admission and/or readmission to health care institutions, and even death. Complex medication regimens promote nonadherence. Education is the cornerstone of adherence—education of the patient, family, and formal and informal caregivers.

Working with older adult patients is an ongoing nursing responsibility. The nurse should plan strategies with the patient and family or friends to encourage **adherence** with prescribed regimens. Daily contact may be necessary at first. Mere ordering of medication does not mean that the patient is able to get the drugs or is taking them correctly. Older adults should have their prescriptions filled at one pharmacy so possible drug interactions can be identified and monitored closely.

Older adults often do not have insurance that includes prescription drug coverage, so they choose to buy food and other necessities before medication. Some will delay purchasing or never purchase the drugs prescribed. The older adult is more apt to experience serious side effects from drug administration than the young or middle-aged adult. If a drug such as ibuprofen (Advil, Motrin) irritates the GI tract, the older adult may not take it because he or she is unaware that another drug such as magnesium hydroxide (Maalox) taken before the ibuprofen dose will decrease this side effect. He or she may not know that food can also decrease gastric irritation from ibuprofen.

Health care professionals (nurses, pharmacists, and health care providers) need to work collaboratively to enhance safety and adherence of older adult patients and to avoid errors and unwarranted concerns. Nurses are in a unique position to educate patients and monitor the effectiveness of the therapeutic regimens. (Refer to Chapter 12 for additional information on medication safety.) A handout of tips for patients on talking with their pharmacist can be found at *www.fda.gov/downloads/Drugs/ResourcesForYou/UCM163349.pdf*.

Cost of medications may be a factor in nonadherence. Potential patient strategies for cutting costs include telling the health care provider about concerns related to expense, asking for senior-citizen discounts, obtaining medication samples from health care providers, buying in bulk for chronic conditions, and buying OTC medications on sale.

HEALTH TEACHING WITH THE OLDER ADULT

A comprehensive discussion of health teaching in the nursing process is presented in Chapter 11. Specific factors that promote adherence in the older adult include the following:

- Ensure that the patient is wearing eyeglasses and has working hearing aids in place, if needed. Check sensory aids to be sure they are clean and working.
- Speak in a tone of voice that the patient can hear; sit facing the patient, and limit distractions.
- Treat the patient with respect; never infantilize; expect that he or she can learn.
- Use large print and bright colors in teaching aids if the patient is vision-impaired.
- Review all medications at each patient visit; ask the patient to bring all medications to each appointment; advise use of only one pharmacy.
- Advise the patient to complete the "vial of life" and keep it in the refrigerator where safety personnel know to look for it. Instruct the patient to keep a list of all medications taken, bring it to all health appointments, and carry it when out of the house.
- Encourage a simple dosing schedule when possible.
- Suspect recently prescribed medication(s) if new confusion or disorientation occurs.
- Encourage the patient to report if a drug is not improving the condition for which it was prescribed.
- Consider use of memory aids such as pill organizers or planners, alarms, blinking lights, or prerecorded messages.

The National Institutes of Health (NIH) websites on aging are excellent resources for both health care providers and older adults and their families. The website for health care providers is *www.nia.nih.gov*; it has sections on health information, research, grants, training, news, and events. The website for older adults is *www.nihseniorhealth.gov*.

Nursing Process
Patient-Centered Collaborative Care

Geriatrics

Assessment

- Assess the older adult's sensorium, mental awareness, and visual and auditory acuity. Assess the patient's use of eyeglasses, and check date of last eye examination.
- Is the patient confused or disoriented? If so, is this state transitory? Does the patient live alone, with or without social support, and need assistance with medications (including costs) or transportation?
- Obtain a history of cardiac, kidney, liver, or GI disorders. Kidney or liver disorders can cause a decrease in the function of these organs and increase the half-life of drugs.
- Assess lab rest results and monitor, as appropriate. Longer drug half-life and frequent drug dosing can result in drug toxicity.
- Assess laboratory test results, and follow up as appropriate.
- Determine whether or not patient takes OTC drugs or supplements (including herbal preparations), how often, and for what length of time. Specifically, ask about laxatives and antacids, which can affect gastric pH, electrolyte balance, and GI motility. Many people do not think of these agents as drugs. Remind patient and family to tell the pharmacist about prescribed drugs when contemplating the purchase of OTC preparations.
- Assess patient's and family's knowledge of the purpose of each medication, how it works, and its possible side effects.
- Assess for patient adherence with taking drugs correctly and reasons for noncompliance. Does the patient have difficulty opening drug containers, or with side effects or adverse effects?

Nursing Diagnoses

- Risk for constipation related to analgesics
- Urinary retention related to drug therapy
- Imbalanced nutrition, less than body requirements, related to metabolism of drugs
- Ineffective health maintenance related to lack of transportation
- Deficient knowledge related to lack of understanding about reason for taking medication
- Noncompliance related to lack of insurance with prescription drug coverage

Planning

- Patient will take prescribed medications as ordered.
- Drug therapy will be effective with no, few, or minimal side effects.

Nursing Interventions

- Monitor patient's laboratory results in relation to kidney and liver function. Are BUN, serum creatinine, and creatinine clearance levels within normal range? Are liver enzymes within normal range? Discuss findings with the health care provider.
- Check patient's serum drug level as ordered and report abnormal findings to nurse manager or health care provider. Remember: Older adults who take water-soluble drugs such as digoxin are likely to have higher blood levels because of reduced body water.
- Communicate with pharmacist or health care provider when drug dose is in question. Check drug references for recommended drug doses for older adults.
- Observe patient for adverse reactions when multiple drugs are being taken. An older adult with hypertension and heart failure might take a diuretic (e.g., hydrochlorothiazide [HydroDIURIL]) and digoxin. The diuretic may cause potassium loss, and if potassium replacement is not ordered, digitalis toxicity may occur. Hypokalemia (low serum potassium) enhances action of digoxin, causing toxicity. Symptoms of digitalis toxicity may be a slow (bradycardia is <60 beats/min) or irregular pulse rate, nausea and vomiting, and blurred vision.
- Recognize a change in usual behavior or an increase in confusion. One of the first signs of drug toxicity is confusion. Report changes to the health care provider.
- Ascertain whether financial problems are preventing patient from purchasing prescribed drugs. Assistance programs are available.

Patient Teaching

General

- Review medications with patient and family, including reason for medication, route of administration, frequency, common side effects, and when to notify health care provider.
- Explain to patient and family the importance of adherence to the drug regimen. Emphasize taking drug as prescribed, discarding unused or old drugs, and keeping a record of medication taken. Remember: Drugs are the property of the patient and may not be disposed of without his or her permission.
- Be available to answer patient's questions. Be supportive of the older adult and the family. Discuss problems related to the medications.
- Advise patient to use one pharmacy to fill prescriptions. Tell patient to inform pharmacist of all OTC and herbal drugs taken.
- Advise patient and family to request a non–childproof cap from the pharmacy if patient has arthritis in the hand joint or difficulty opening childproof bottle caps. Patient may need to sign for this at the pharmacy; safety of children or pets in the environment must be ensured.

- Counsel patient not to share prescribed medications with others or to take medications prescribed for another person.

Self-Administration

- Advise patient to keep a medication record of drugs and when they are to be taken. Consider offering patient a sample log for recording information. This removes barriers, increases drug adherence, and avoids drug errors.

Diet

- Encourage patients controlling hypertension with a potassium-wasting diuretic (e.g., hydrochlorothiazide) to eat foods rich in potassium (bran cereal, tomatoes, raisins, potatoes, bananas, avocados) and to take potassium supplements if recommended by the health care provider.
- Advise patient about how to maintain a generally well-balanced diet, and give examples.

Side Effects

- Advise patient and family to immediately report mental and physiologic changes (confusion, GI bleeding) to health care provider.

Cultural Considerations

- Recognize that language difficulties may interfere with older adults' understanding of the prescribed drug regimen if English is not their first language.
- Provide additional time for verbal and written explanation to ensure that the older adult will take drugs as prescribed.
- Do not assume that lack of eye contact means the patient is not listening or does not care; it might indicate respect. More traditional or older individuals in some cultures do not maintain eye contact.

Evaluation

- Evaluate compliance with the drug regimen, and answer any questions the older adult may have.
- Evaluate drug effect, and ascertain side effects or adverse reactions.

CRITICAL THINKING CASE STUDY

An older adult patient has osteoarthritis. The patient had previously taken aspirin for the condition and later was prescribed naproxen (Naprosyn). Both drugs caused GI distress. The health care provider discontinued the naproxen and prescribed celecoxib (Celebrex) 100 mg twice a day. Celecoxib is a non-opioid, cyclooxygenase-2 (COX-2) inhibitor.

1. How does celecoxib differ from naproxen? (See Chapters 25 and 26.)
2. Describe the advantages and disadvantages of taking celecoxib for osteoarthritis.
3. What is the rationale for checking the patient's renal and liver function before prescribing celecoxib? Explain your answer.
4. What should be included in the nursing assessment in regard to the patient's physical and drug histories?

   The patient states that the arthritic pain is not relieved with the new drug. The patient wants to take naproxen with the celecoxib.
5. Explain the effects of these two medications when taken together.
6. What is the most appropriate response to the patient's request? Explain your answer.
7. Develop a teaching plan for the patient that includes medication use and nursing measures to relieve pain.

NCLEX STUDY QUESTIONS

1. A patient has nine medications prescribed to take daily. Which are common reasons for nonadherence to the drug regimen in the older adult? (Select all that apply.)
   a. Taking multiple drugs at one time
   b. Impaired memory
   c. Decreased dexterity
   d. Increased mobility
   e. Increased visual acuity

2. The nurse is reviewing a patient's list of medications with the patient. The nurse understands that the older adult's slower absorption of oral medications is primarily because of which phenomenon?
   - a. Decreased cardiac output
   - b. Increased blood flow
   - c. Decreased enzyme function
   - d. Increased pH of gastric secretions
3. The older adult patient has questions about oral drug metabolism. What is the most important information to include in this patient's teaching plan?
   - a. First-pass effect
   - b. Enzyme function
   - c. Glomerular filtration rate
   - d. Motility
4. A 97-year-old patient asks why a protein supplement has been prescribed. What is the nurse's best response?
   - a. "You have increased circulation of free drug."
   - b. "You have decreased hepatic size."
   - c. "You have decreased calcium absorption."
   - d. "You have increased motility."
5. An 80-year-old patient complains of recent onset of insomnia, saying, "If only I could get to sleep!" If a drug is prescribed, which drug characteristics would be best for this situation? (Select all that apply.)
   - a. Short-intermediate acting
   - b. Rapidly eliminated
   - c. Slowly eliminated
   - d. Multiple metabolites
   - e. Few metabolites
6. An older patient has just started on hydrochlorothiazide (HydroDiuril) and is advised by the health care provider to eat foods rich in potassium. What is the nurse's best recommendation of foods?
   - a. Cabbage and corn
   - b. Pineapple and orange juice
   - c. Bran cereal and raisins
   - d. Brown rice and fish
7. Insomnia is a frequent complaint voiced by the patient. What are the most important elements for the nurse to include in the teaching plan? (Select all that apply.)
   - a. There are a limited number of FDA-approved medications to treat insomnia.
   - b. Benzodiazepines with long half-lives are preferred.
   - c. 17% of the older adult population take hypnotics.
   - d. Temazepam is to be taken 1 to 2 hours before bedtime.
   - e. Triazolam should be tapered rather than abruptly stopped.

Answers: 1, a, b, c; 2, d; 3, a; 4, a; 5, a, b, e; 6, c; 7, a, d, e.

NCLEX Study Questions

Health and illness care has shifted from traditional institutions to community settings. The faces of a community are many, varied, and ever-changing. With the movement of health care into the community, nurses—more than any other health care provider—have the opportunity to shape the health care of society. This chapter describes selected aspects of medication administration of prescription, over-the-counter (OTC), and herbal preparations within each of the major community settings: home, school, and work. In all settings, patient safety is the primary concern. (Refer to Chapter 13 for a detailed discussion of medication administration.)

This chapter discusses a small, but significant, portion of the nurse's role in a variety of community settings. Specifically, the focus is on selected concerns associated with the administration of medications and the need to practice in accordance with the Nurse Practice Act of a specific state. The role of the nurse in drug administration is growing in complexity. Most medications are taken by community-dwelling residents (not hospitalized patients), which clearly shows the importance of patient education in all settings. The nurse in the twenty-first century must have a strong knowledge base.

The process of medication administration in the home, school, and work site must be consistent with professional, legal, and regulatory requirements. In each setting, it must first be determined what the nursing personnel will teach patients about medications and then the routes by which the medications can be administered. Once these decisions have been made, criteria for administration, instruction and patient teaching, and ongoing supervision must be developed, implemented, and evaluated. Mechanisms for communication and electronic or paper tracking must be in place to promote efficacy of the medication and avoidance of untoward responses and medication errors.

With the escalating costs of medications, the nurse in any community setting is likely to meet patients who need assistance paying for their prescriptions. A possible resource for the nurse and patient are pharmaceutical companies' patient-assistance programs (PAPs). Some PAPs provide medications for free or at a reduced cost, but often patients must demonstrate that they do not qualify for private or public health insurance and that their income is below a certain level. An application process is required; the health care provider, nurse, or social worker may need to apply for the patient. Online resources that assist in finding PAPs or other programs include rxassit.org (sponsored by Volunteers in Health Care), RxHope.com (supported by the Pharmaceutical Research and Manufacturers of America), and PPARx.org (Partnership for Prescription Assistance).

The backbone of health promotion and disease prevention is the patient knowledge base. The role of the nurse in establishing this base is critical. (A comprehensive discussion of patient teaching is offered in Chapter 11.) Assessment of learning needs and styles is another essential component to achieving the identified teaching goal.

PATIENT TEACHING

Regardless of the state and agency regulations related to medication administration in community settings, the following format for patient teaching associated with medication administration is recommended. Hints are grouped into five categories: (1) general, (2) diet, (3) self-administration, (4) side effects, and (5) cultural considerations.

General

Patient safety is of primary concern, so a patient's physical abilities require ongoing assessment. Capabilities of the patient may be temporarily impaired with the use of certain drugs (e.g., narcotics, selected eye medications, psychotropics). It is essential that patients be advised not to drive a vehicle or operate hazardous machinery during such times and to use caution at all other times. It is appropriate to discuss with patients and families what situations in the daily routine require full alertness and cannot be influenced by medication for the sake of safety.

Numerous safety concerns are associated with the storage of medications. Medications should be kept in their original labeled containers, with childproof caps when needed, and stored away from light and moisture.

Advise the patient and family about any necessary laboratory tests to monitor the blood level of the medication and any possible drug-laboratory test interactions. Also educate the patient and family about assessments—such as heart rate, blood pressure, or blood sugar levels—that should be done before taking the medication. This information, and all other information about the drug regimen, should be provided as written instructions (or audio instructions if the patient is sight impaired or unable to read). Large print may be helpful or necessary.

Important yet frequently misunderstood components of the instructions are the expected therapeutic effect and the length of time required to achieve a therapeutic response from the medication. These vary widely among different medications (e.g., most opioids act within 30 minutes; many antibiotics act within 24 hours; some psychotropics act within 6 weeks). Patient understanding of the expected time frame for results can markedly diminish concerns and promote adherence to the therapeutic plan.

The patient and family must also be aware of the need to have an adequate supply of necessary medications available at all times: at home, school, work, and while traveling. It is best to order prescription refills in advance. If the pharmacy is local, at least 1 week should be allowed; several weeks should be allowed if drugs are ordered through the mail. It is a good idea to pack extra medication when going on trips, both short and extended. This is preferred at all times and is essential for foreign travel.

Advise the patient and family to contact the health care provider before using OTC preparations. Common OTC preparations that may cause problems are laxatives, diet aids, cold and cough preparations, nonsteroidal anti-inflammatory drugs (NSAIDs), antacids, and medications for sleep. Reinforce with the patient and family the importance of follow-up appointments with health care providers. Encourage wellness checkups, including preventive and restorative dental care, because the presence of other conditions may affect the current therapeutic regimen. In addition, advise patients of the need to complete laboratory studies in a timely manner. Encourage patients to wear medical alert bands that indicate the patient's condition or disease (e.g., diabetes, parkinsonism), medications, and allergies (Herbal Alert 9-1). See Chapter 12 for guidelines on the safe disposal of drugs.

Reinforcement of the availability of community resources is important. Availability does not always equate with accessibility, so the patient or family needs to know how to mobilize resources according to individual needs. Matching community resources and patient needs is a prerequisite. While acknowledging the variability of each patient, family, and setting need, the following are offered as examples:

- The Internet, medical libraries with medical librarians, and telephone listings can direct patients and families to contact information for associations of relevant health conditions (e.g., American Heart Association, American Cancer Society). Most agencies and associations have or can direct the caller to a wealth of health education resources available in a variety of media (e.g., print, audio, video, Braille). In addition, many organizations have "Ask a Nurse" programs.
- Houses of worship may have volunteer outreach groups to pick up prescriptions and deliver them to homebound patients.

HERBAL ALERT 9-1

Community

Encourage the patient to consult the health care provider before taking herbal preparations or vitamin and mineral supplements; some products may interact with prescription or over-the-counter medications.

- Pharmacists can frequently clarify a patient's or family's concern over the telephone.
- Meals on Wheels enables patients to remain at home and adhere to taking medications with food.
- In a college town, students of the health professions may be motivated caregivers to assist patients or families in the community.

Patients or families need to be encouraged to have a contact person for their concerns and questions, frequently a nurse. Use of appropriate resources is likely to increase compliance with and effectiveness of the therapeutic regimen.

Diet

Nurses should advise patients or families about possible drug-food interactions, detailing which foods are to be avoided and which foods are encouraged for specific nutrient value. For example, tyramine-rich foods are contraindicated with monoamine oxidase inhibitors (MAOIs), and potassium-rich foods are recommended for patients taking potassium-wasting diuretics. Alcohol may be contraindicated with selected medications. Lists of foods, with pictures when appropriate, may be helpful to patients and their families.

Self-Administration

Based on the level of the patient's or family's knowledge, instructions should be given on all skills related to the drug regimen, how to take the pulse for patients who take digitalis preparations, how to use and clean inhalers, how to administer parenteral medications, and how to decrease the risk for infection in patients taking immunosuppressants. The nurse should allow time for instruction and questions, including demonstration of the skill and return demonstration. Patients should be given graphic illustrations for future reference as appropriate. It is essential that the nurse provide the patient or family with the name and telephone number of a contact person for questions and concerns. It is not uncommon for a patient or family member to return-demonstrate a skill (e.g., administration of insulin, use of inhaler) with relative ease and then forget information or become confused when attempting self-administration of the drug while alone. Resources must be provided to the patient and family if this occurs.

Side Effects

The patient or family should be advised about general side effects of medications. This is not done to scare patients but rather to let them know what they might expect. Patients should know when and how to notify their health care provider if they experience an adverse reaction; this information should be kept in an easily accessible location for ready access if needed.

Cultural Considerations

Initially, the nurse assesses the patient's personal beliefs. Based on these beliefs, the nurse then modifies communication to meet patient and family cultural practices. The nurse should communicate respect for the patient or family culture at all times. It is important for the nurse to assess his or her own beliefs and biases related to cultural competence and diversity, and then evaluate the effectiveness of interactions and their acceptability within the cultural realm. Culturally sensitive and competent health care promotes patient and family adherence to the therapeutic regimen. Respect for cultural diversity may be demonstrated by inclusion of traditional practices into the plans for improved communication, health promotion, and disease prevention. Refer to Chapter 3 for a discussion of cultural differences.

COMMUNITY-BASED SETTINGS

Home Setting

The home setting provides nurses with opportunities and challenges related to medication administration. The patient and family are generally more comfortable in their home; the nurse is a guest. The nurse has a comprehensive view of the patient and family during a home visit (e.g., support system, resources, adherence). A question that may quickly arise is, "Who can administer medications in the home setting?" The response does not develop so quickly.

In general, medications are administered by licensed nurses in the home setting according to the health care provider's order. Drugs that are administered by nursing personnel in the home must be approved by the U.S. Food and Drug Administration (FDA). The nurse must provide instructions about the medication to the patient and family. The licensed nurse may also administer the medication on a short-term basis for a disease-related condition if the patient or a caregiver with an order from the health care provider is unable to do so.

The order from the health care provider must be current and complete (drug, dosage, frequency, route of administration, and signature). The medication must be labeled by the pharmacist or health care provider; the nurse should not administer any medication that is not properly labeled. It is the nurse's responsibility to contact the health care provider, pharmacist, or other contact identified by the agency with any concerns about the medication for a specific patient. The expiration date must be checked at the time of each administration. Storage and deterioration of the medication are also evaluated. Significant side effects, allergies, and adverse reactions are reported promptly to the health care provider. Each patient is assessed for allergies before administering the drug.

The establishment of policy and procedures for medication administration promotes safety and consistency; however, errors do occur. When a medication error occurs, it is reported to the health care provider and nursing supervisor. The patient and family are instructed when to notify the nurse or health care provider if an adverse drug reaction is suspected. Ultimately, the health care provider should be notified of all adverse drug reactions.

⚡ SAFETY: Preventing Medication Errors

Community Settings

- Do not give or take medications in the dark; proper lighting is important to avoid errors.
- Apply the rights of medication administration (see Chapter 13).
- Dispose of unused medications in a safe manner (see Chapter 12).

An agency policy for medication administration generally addresses guidelines for specific medications, such as allergy vaccines, chemotherapy, gamma globulin, gold therapy, experimental drugs, and narcotics. The guidelines are agency-specific and may include that the first dose of allergy vaccine be given by the health care provider in a controlled environment or that family members be taught how to administer narcotics to the patient by the parenteral route if the order is so written by the health care provider. When the order is discontinued, the health care provider should be notified if any unused narcotics are in the home. Licensed practical nurses may not administer gamma globulin intravenously, and family members may not be taught to administer selected drugs (e.g., iron dextran [Imferon]). Chemotherapy for cancer commonly presents a special challenge. The patient's blood work must be current before the administration of chemotherapeutic drugs, the patient must be under regular and ongoing care of a health care provider, and safety requirements may be identified (e.g., gloves and goggles may be used).

Certified home health aides work under the supervision of a registered nurse. Home health aides are commonly asked to administer medications to a patient by the patient, family, or friends. The home health aide may receive pressure to administer medications, but legally home health aides may only *assist* with medications the patient customarily self-administers.

Additional challenges related to medication administration in the home setting include adherence to the therapeutic regimen, especially the right drug, right dose, and right time. Some patients need, but do not have, a primary caregiver to oversee follow-up with medications and other aspects of care. The quality and preparation of meals may also be a factor related to medication administration, such as what foods to avoid with certain medications and what foods complement a medication. In addition, it may be difficult for patients to get their medications and to get them in a timely manner. Coordinated skill may be required by the patient or family—for example, with use of an inhaler or administration of insulin. In all of these situations, the nurse is frequently the person who coordinates the resources.

School Setting

Administration of medications in the school setting is of special concern. One study reports that in any given 2-week period, about 13 million children in grades kindergarten through senior year take medications. The most frequently taken medications are OTC preparations and prescription medications for attention deficit hyperactivity disorder (ADHD) or asthma. In addition, there has been a dramatic increase in the kinds of medications taken at school: from 58 different types in the late 1980s to more than 200 currently.

School health services are not immune to the phenomenon of downsizing personnel, and many school systems are dealing with questions like "Where are the nurses?" and "Who is responsible for the administration of medication?" In the absence of federal and state law, some school districts have elected not to employ school nurses. The average national caseload for a school nurse is more than 3,100 students, despite the long-standing recommendation of having one registered nurse for every 750 students. Coupled with this is the impact of a federal law that entitles children with disabilities to attend public schools in their residential areas. It is not unreasonable to assume that these children have special needs that may require professional nursing services.

Massachusetts has developed a model with the goal "to develop regulations that provide minimum standards for the safe and proper administration of prescription medications in the Commonwealth schools." This model has many strengths including representation of professional associations, community groups, and regulatory bodies. Consistent consent forms have been designed and adopted, and orientation and training programs have been instituted for all personnel in school health positions. The established regulations apply to both public and nonpublic schools. The Massachusetts model appears to have applicability to other states that are grappling with the important child health issue of medication administration in schools.

It is essential that nurses be aware of the policies and procedures for medication administration in their own state, county, and school system. Standardized policies for medication administration are necessary for safe practice and promote self-management programs for students with chronic conditions such as asthma and diabetes. Nurses must be actively involved in developing these policies and in ensuring that the needs of individual students are met.

In some states or school systems, people who are not nurses may be responsible for medication administration. This presents additional concerns that must be addressed, such as adherence to instructions and to the principle that medication administration is a process, more than merely "giving the student a pill." A major component of medication administration is assessment of the need for the medication and its effectiveness of action. The effectiveness of action includes being alert to side effects and adverse reactions that the patient may experience.

The National Association of School Nurses (NASN) released their Summary of Position Statement on the Administration of Medications in 2012. This document contains helpful information, including delegation, alternative medications, controlled substances, emergency medications, and research medications. The full position statement is available at *www.nasn.org*.

Child care and adult day care services have similar rules for the administration of medications. In general, these facilities administer medications or supervise self-administration within the Nurse Practice Act of the specific state. In addition, most facilities require labeling of medications in accordance with the Pharmacy Rules and Regulations of the specific state. Guidelines for safe storage of medications must be followed, including the rule that medications be accessible only to personnel responsible for their administration or for distribution of self-administered medications. Some states require that internal and external medications be stored separately. Care must be taken to ensure that prescription medications be used only by those for whom the medication was prescribed.

Work Setting

Healthy employees are more productive than unhealthy employees. This fact, coupled with the escalating costs of health care and insurance, has inspired many businesses to offer some type of health care at the work site. This care may range from emergency first aid and work-related safety initiatives to the provision of primary care and referral services.

Occupational and environmental health nursing is a specialty practice that provides for and delivers health care services to workers and worker populations. The practice is autonomous and focuses on the promotion, protection, and restoration of workers' health within the context of a safe and healthy work environment. According to the American Association of Occupational Health Nurses (AAOHN), occupational and environmental health nurses may function in a variety of roles, including but not limited to solo practitioner, manager, educator, consultant, nurse practitioner, case manager, and corporate director, and these nurses often work with the other members of an occupational health and safety team (e.g., medicine, safety, industrial hygiene).

The nurse needs to be aware of the policies and procedures for administration of medication at the specific work site. There is great diversity in policy and procedure among settings. Following are two examples of the many current practices at work sites:

- At one setting, the registered nurse follows protocols for selected employee complaints (e.g., back injuries: acute and chronic; burns: thermal, chemical, and electrical; eye emergencies; herpes; adult immunizations). Each protocol includes the following areas with relevant information for the specific complaint: assessment, treatment/medications, patient education, referral, and follow-up. Medications are identified as appropriate and noted under the treatment/medications section with the stated drug, dosage, frequency, and route.
- Another work site has established self-care stations for minor illnesses and injuries. Each station has designated criteria for use. Examples include stations for colds, superficial cuts, and menstrual cramps. Employees are familiarized with this service as part of the orientation process. Upon arrival at the stations, employees note date, time, and signature on the sign-in sheet posted at each station. They indicate their chief complaint or reason for seeking medication and the specific medication they have taken from the OTC preparations supplied at each station.

An excellent resource for care of patients in the work setting is the AAOHN website at *www.aaohn.org*.

Nursing Process
Patient-Centered Collaborative Care

Overview of Medication Administration

Assessment

- Obtain appropriate vital signs and relevant laboratory test results for future comparisons and evaluation of the therapeutic response.
- Obtain drug history (prescription, OTC, and herbal preparations), including drug, food, latex, and environmental allergies.
- Identify patients/students/employees at high risk for reactions.
- Assess patient's/student's/employee's capability to follow therapeutic regimen.
- Determine patient/student/employee learning needs.

Nursing Diagnoses

- Risk for injury related to possible adverse reaction
- Deficient knowledge related to therapeutic regimen
- Risk-prone health behavior (taking medications not as prescribed or without first contacting health care provider)

Planning

- Identify goals.
- Promote therapeutic response, and prevent or minimize adverse reactions.
- Identify strategies to promote adherence.
- Identify interventions.

Nursing Interventions

- Prepare equipment and environment; wash hands.
- Verify patient/student/employee identification.
- Determine allergies and other assessment data.
- Check drug label three times; check expiration date.
- Be certain of drug calculation; verify dose with another registered nurse as necessary.
- Pour liquids at eye level on flat surface.
- Avoid contact with topical and inhalation preparations.
- Administer only drugs you have prepared.
- Assist patient to desired position.
- Discard needles and syringes in "sharps" container.
- Keep all drugs stored properly, especially related to temperature, light, and moisture.
- Follow policy related to discarding drugs and controlled substances.
- Report drug errors immediately.
- Document all appropriate information in a timely manner.
- Record effectiveness of drugs administered and reason for any drugs refused.

Cultural Considerations

- When language barriers are present, use literature and videos in the patient's preferred language and with pictures of the patient's cultural group to promote adherence with health interventions.
- Obtain an interpreter when necessary; do not rely on family members, who may not fully disclose because of honor or guilt. Provide interpreter with the same ethnic background and gender if possible, especially with sensitive topics.
- When offering a prescription, instructions, or pamphlets to Asians and Pacific Islanders, use both hands to show respect.
- Include grandparents when providing support and health teaching for African Americans.
- Encourage patients to disclose the use of folk healers and treatments prescribed. Incorporate harmless and nonconflicting practices into the therapeutic plan.

Evaluation

- Evaluate effectiveness of medication(s) administered.
- Identify expected time frame of desired drug response; consider need for modification of therapy.
- Determine patient/student/employee satisfaction with regimen.
- Determine patient/student/employee knowledge of medication regimen.

CRITICAL THINKING CASE STUDY

The junior high school nurse is reflecting on the activities and events at the school during the last several weeks. Several students have chronic conditions and require medications during the school day for optimum effectiveness.

1. What is key information for medication administration in the school setting?
2. A student reports to the nurse's office and states that he needs his medicine for his chronic condition. What must be in place before the nurse can administer medication to the student?
3. A student asks the school nurse about starting herbal products "to feel stronger." What is the best response by the nurse?
4. The school has a culturally diverse student population. What cultural resources are recommended to provide the students with the optimal level of care?

NCLEX STUDY QUESTIONS

1. The nurse is preparing a health teaching session for a patient. Which topic is the most important for the nurse to include in health teaching?
   a. Foods to avoid
   b. Patient safety
   c. Storage of medication
   d. Laboratory test results
2. Community-dwelling individuals may take over-the-counter (OTC) preparations. The nurse includes in health teaching related to OTC preparations the importance of contacting the health care provider in which situations? (Select all that apply.)
   a. When planning to use OTC products
   b. When symptoms persist
   c. When prescriptions are filled
   d. When adding an herbal product
   e. When quick relief is not achieved
3. Patients in the community often have questions about how long it takes for various types of medications to "work." The nurse correctly reports which general guidelines? (Select all that apply.)
   a. Psychotropics—6 weeks
   b. Antibiotics—24 hours
   c. Opioids—many within 30 minutes
   d. Antiinflammatories—within 1 week
   e. Glucocorticoids—immediately
4. An adult Hispanic patient comes to the mobile health unit for evaluation of his cardiac condition. An interpreter will be present during the visit. Which qualities are most important for the nurse to consider when matching an interpreter with a patient? (Select all that apply.)
   a. About same age as patient
   b. Same ethnicity as patient
   c. Same gender as patient
   d. Member of patient's family
   e. Similar likes and hobbies as patient

5. The role of the nurse in the community setting is multifaceted and commonly includes which actions? (Select all that apply.)
   - **a.** Assist patient to identify community resources.
   - **b.** Take patient to health appointments.
   - **c.** Emphasize importance of follow-up health appointments.
   - **d.** Educate on safe disposal of medications.
   - **e.** Administer daily oral medications.
6. The nurse makes a home visit to a patient who was discharged from the hospital the previous day. Which are regulations for the nurse administering medications in the home setting to follow? (Select all that apply.)
   - **a.** May administer medication on a long-term basis
   - **b.** Must be an FDA-approved drug
   - **c.** Drug is ordered by the health care provider
   - **d.** May administer drug on a short-term basis if caregiver is unable
   - **e.** May compound medications in the home
7. The school nurse is updating the policy and procedure manual for medication administration. Which are examples of content? (Select all that apply.)
   - **a.** The nurse is accountable for state law and regulations.
   - **b.** Medication can be given with parents' verbal permission.
   - **c.** Policy to address how OTC medications are received, stored, and labeled
   - **d.** Medications must be stored in a secure, locked, and clean area.
   - **e.** Electronic health record must be maintained on a daily basis.

Answers: 1, b; 2, a, d; 3, a, b, c; 4, a, b, c; 5, a, c, d; 6, b, c, d;
7, a, c, d.

CHAPTER 10

The Role of the Nurse in Drug Research

In the United States, all prescription drugs must be approved by the U.S. Food and Drug Administration (FDA) before they are made available on the market. Drug studies take place in a variety of inpatient and outpatient settings. Drug research involves risk and is a "high-cost item," with the estimated average cost to develop each new drug being more than $1 billion.

Drug research and development are complex processes that are of particular interest and importance to professional nursing practice. The nursing process facilitates the integration of cutting-edge research.

This chapter is devoted to a description of basic ethical principles governing informed consent and risk-to-benefit ratio, preclinical testing and human clinical experimentation, and the nurse's role and nursing process in clinical drug trials.

BASIC ETHICAL PRINCIPLES

Four basic ethical principles are relevant to research involving human subjects: respect for persons, beneficence, justice, and veracity. These are integral to the issues of informed consent and risk-to-benefit ratio in research involving human beings.

Respect for Persons

Individuals undergoing treatment in any health care system should be treated as independent persons who are capable of making decisions in their own best interests. Individuals whose decision-making capability is diminished are entitled to protection. The nurse can determine this with consistent reassessment of the patient's cognitive state. Patients should be made aware of the alternatives available to them in their health care, as well as the consequences that stem from those alternatives. The patient's choice should be honored whenever possible. It is imperative that the nurse recognize when the patient is not capable of rational decision making and therefore entitled to protection.

Autonomy is an integral component of respect for persons. **Autonomy** is the right to self-determination. In health care settings, health care personnel must respect the patient's right to make decisions about themselves, even if the decision is not what the personnel want or think is best for the patient. Generally, patients can refuse any and all treatments (right of autonomy) except when the decision poses a threat to others—such as with tuberculosis, when taking medications is legally mandated. Patients have the right to refuse to participate in a research study and may withdraw from studies at any time without penalty of any kind.

Beneficence

Beneficence is the duty to do good and to not harm others, to maximize possible benefits, and to minimize possible harm that might occur in research. It is often not possible to know whether something is beneficial unless it is tested and individuals have been exposed to the risks. A question central to this issue is: Who makes this decision—the patient, or those caring for the patient?

Justice

Justice requires that all people be treated fairly. Expansion of justice includes equal access to health care for all. Justice can be limited when it interferes with the rights of others. The principle of justice, in the context of clinical drug trials, means that social benefits and burdens can be allocated objectively and that those with equivalent circumstances should be treated equally. A challenge to the nurse is the allocation of scarce resources.

Veracity

Veracity requires health care personnel to tell the truth and the whole truth. When there is "bad news" to tell the patient, the health care provider may be reluctant to tell the truth and answer questions honestly. The patient has the right to know the truth, including the bad news.

INFORMED CONSENT

Informed consent has its roots in the 1947 Nuremberg Code. The two most relevant aspects of this Code are the participant's right to be informed and the fact that participation is voluntary, without coercion. If the nurse suspects that a patient is being coerced to participate in a study, the nurse is obligated to report this promptly to the party named on the informed consent (the patient should have a copy of the consent for reference). **Informed consent** has dimensions beyond protection of the individual patient's choice and includes the following:

1. Promotion of individual autonomy
2. Protection of patients and subjects from harm
3. Avoidance of fraud and duress in health care
4. Encouragement for professionals to be thorough and clear in communicating information
5. Promotion of educated decision making among patients
6. Promotion of self-determination of the patient

It is the role of the health care provider, *not* the nurse, to explain the study to the patient (including what is expected of the patient) and to respond to questions. While giving written consent, the patient must be alert and able to comprehend.

It is the nurse's role to protect patients from any anticipated harm. The nurse, in collaboration with the health care provider and pharmacist, must be knowledgeable about all aspects of a drug study, including all inclusion and exclusion criteria for participants (Box 10-1).

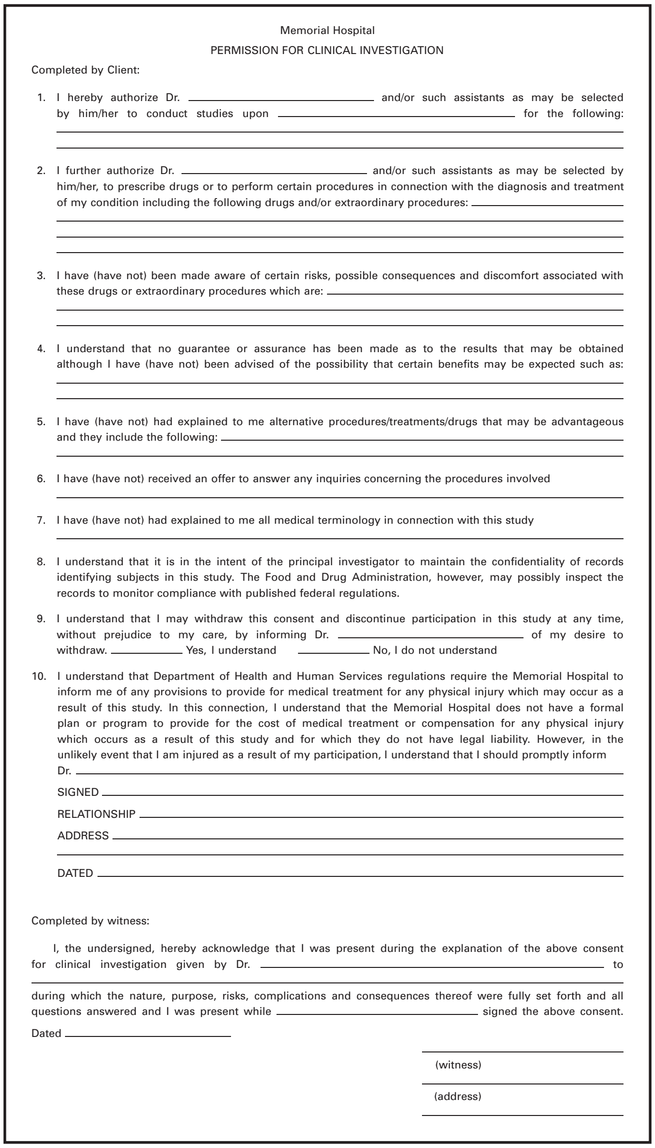
BOX 10-1 INCLUSION AND EXCLUSION CRITERIA FOR A HYPOTHETIC PROTOCOL FOR AN EXPERIMENTAL DIURETIC MEDICATION

Inclusion

- Persons between 18 and 65 years of age
- Persons with weight between 50 and 100 kg
- Persons who receive cardiac medications only if dose has been stable for past 3 months
- Persons on sodium-restricted diet

Exclusion

- Pregnant or nursing women
- All women of childbearing age who do not use oral contraceptives
- Persons with severe damage or disease of cardiac, hepatic, renal, neurologic, or musculoskeletal system
- Persons with clinically significant laboratory values



Memorial Hospital

PERMISSION FOR CLINICAL INVESTIGATION

Completed by Client:

1. I hereby authorize Dr. ______________ and/or such assistants as may be selected by him/her to conduct studies upon ______________ for the following: ______________
2. I further authorize Dr. ______________ and/or such assistants as may be selected by him/her, to prescribe drugs or to perform certain procedures in connection with the diagnosis and treatment of my condition including the following drugs and/or extraordinary procedures: ______________
3. I have (have not) been made aware of certain risks, possible consequences and discomfort associated with these drugs or extraordinary procedures which are: ______________
4. I understand that no guarantee or assurance has been made as to the results that may be obtained although I have (have not) been advised of the possibility that certain benefits may be expected such as: ______________
5. I have (have not) had explained to me alternative procedures/treatments/drugs that may be advantageous and they include the following: ______________
6. I have (have not) received an offer to answer any inquiries concerning the procedures involved ______________
7. I have (have not) had explained to me all medical terminology in connection with this study ______________
8. I understand that it is in the intent of the principal investigator to maintain the confidentiality of records identifying subjects in this study. The Food and Drug Administration, however, may possibly inspect the records to monitor compliance with published federal regulations.
9. I understand that I may withdraw this consent and discontinue participation in this study at any time, without prejudice to my care, by informing Dr. ______________ of my desire to withdraw. ________ Yes, I understand ________ No, I do not understand
10. I understand that Department of Health and Human Services regulations require the Memorial Hospital to inform me of any provisions to provide for medical treatment for any physical injury which may occur as a result of this study. In this connection, I understand that the Memorial Hospital does not have a formal plan or program to provide for the cost of medical treatment or compensation for any physical injury which occurs as a result of this study and for which they do not have legal liability. However, in the unlikely event that I am injured as a result of my participation, I understand that I should promptly inform Dr. ______________

SIGNED ______________

RELATIONSHIP ______________

ADDRESS ______________

DATED ______________

Completed by witness:

I, the undersigned, hereby acknowledge that I was present during the explanation of the above consent for clinical investigation given by Dr. ______________ to ______________ during which the nature, purpose, risks, complications and consequences thereof were fully set forth and all questions answered and I was present while ______________ signed the above consent.

Dated ______________

____

FIGURE 10–1 An example of informed consent.

Figure 10-1 shows an example of Permission for Clinical Investigation, and Box 10-2 shows an Informed Consent Checklist.

RISK-TO-BENEFIT RATIO

The risk-to-benefit ratio is one of the most complex problems faced by the researcher. All possible consequences of a clinical study must be analyzed and balanced with the inherent risks and the anticipated benefits. Physical, psychological, and social risks must be identified and weighed against the benefits. A requirement of the Department of Health and Human Services (DHHS) is that institutional review boards (IRBs) determine that risks to subjects be reasonable in relation to the anticipated benefits, if any, for subjects. No matter how noble the intentions, the calculation of risks and benefits by the researcher cannot be totally accurate or comprehensive.

BOX 10-2 INFORMED CONSENT CHECKLIST

- Participates voluntarily
- Identifies related drugs, treatments, and techniques
- Describes benefits and risks
- Describes other forms of treatment available
- Describes laboratory tests to monitor patient's reactions
- Identifies extent of confidentiality of results
- Describes availability of emergency treatment for illness/injury, if any
- States compensation for study-related injury, if any
- States compensation for participation, if any
- Writes consent clearly and understands easily at tenth-grade reading level
- Provides name and telephone number of contact person for patient questions and concerns

Varying amounts of time are required for the process of identifying a potentially useful chemical and having it become available to the general population; in many cases, 15 years may elapse. Only 1 in 10,000 potential drugs endures the research and development process and is used in a clinical situation.

OBJECTIVES AND PHASES OF HUMAN CLINICAL EXPERIMENTATION

Good Clinical Practice (GCP): Consolidated Guideline, an international ethical and scientific standard for design, conduct, performance, monitoring, auditing, recording, analysis, and reporting, is the foundation of clinical trials. Guidance and information sheets are available from the FDA on multiple topics related to clinical trials. Examples include information sheets for IRBs and Clinical Investigators and Choice of Control Groups and Related Issues in Clinical Trials. Websites with this and expanded information are the U.S. National Institutes of Health at http://clinicaltrials.gov and TrialsCentral at http://trialscentral.org. In addition, the World Medical Association **Declaration of Helsinki** has crafted ethical principles for medical research involving human subjects. This and other relevant websites are listed at the end of the chapter.

Preclinical Testing

Preclinical testing consists of in vitro and in vivo systems. In vitro experimentation is generally conducted in a test tube or other laboratory equipment, and in vivo testing is conducted with living organisms. This testing is followed by toxicity screening to identify (1) abnormal changes in animal organs related to drug administration and (2) the parameters of the safe therapeutic dose. Control and experimental groups of animals are compared. Participants in the **experimental group** receive the experimental intervention or treatment. Those in the **control group** do not receive the experimental intervention or treatment and provide a baseline against which to measure the effects of the treatment. Before initiating human studies, an assessment is made of the seriousness of the disease to be treated using this drug in relation to the drug's toxicity.

Human Clinical Experimentation

For every 5,000 to 10,000 compounds screened as potential new medications, only 5 are entered into clinical trials. To bring a new drug to market takes an average of 6 to 15 years, and costs continue to rise. The **FDA Modernization Act of 1997** increased the minimum age for subjects of human clinical experimentation. The Act has five provisions, one of which requires pediatric evaluation of new products intended for use by children. The Act advocates for children and appropriate testing for drugs to be used by the pediatric population. The automatic universal exclusion of children from clinical trials is not justified. Refer to Chapter 2 for a listing of the provisions of this act.

Drug research was historically done only with white males, causing uncertainty as to the validity of research results for people of other ethnicities and for white women. In 1993, Congress passed the NIH Revitalization Act to include white women and minorities.

Clinical experimentation in drug research and development encompasses four phases, each with its own objectives (Figure 10-2). A multidisciplinary team approach (nurses, physicians, pharmacologists, statisticians, and research associates) is required to ensure throughout the phases that the data collected will answer the clinical questions. A brief description of each phase follows.

Phase I

Phase I trials are primarily designed to assess safety. Their objectives are to determine the human dosage range based on response in healthy human beings and to identify the pharmacokinetics (i.e., absorption, distribution, metabolism/biotransformation, and excretion/elimination) of the drug. Progression to the next phase occurs if no serious adverse effects are demonstrated, the drug is eliminated in a reasonable amount of time, and the dose range is below that known to induce pathology in animals.

Phase II

The objective of phase II is to demonstrate the safety and efficacy of the drug in subjects who have the disease the drug is designed to treat. Phase III is initiated only when acceptable efficacy and safety data are generated and clearly documented in Phase II.

Phases III and IV

Phase III studies involve large numbers of subjects who have the disease intended for treatment. The objectives of Phases III and IV are to demonstrate the safety and efficacy of the drug for a wide patient population and to include long-term data if a chronic regimen is under consideration. Phase IV studies may also examine potential new indications for approved drugs. The sponsor submits all relevant and analyzed data in a new drug application (NDA) to the FDA. The FDA decides to approve, reject, or recommend withdrawal or resubmission. After the NDA research has been approved, Phase IV addresses the long-term use of the drug.

The pharmaceutic industry is eager to get new drugs to market. Delays in the FDA approval process were decreasing the valuable life of a drug's patent; therefore, in 1992 Congress passed the **Prescription Drug User Fee Act,** which provided the FDA with funds to expedite the review process. As a result, the average drug approval time has decreased from 30 to 12 months.

Challenges and new directions await clinical trial programs of the future. Specifically, future trials are needed for certain populations at risk, such as profiling patient and tumor for cancer-related trials. In addition, research is needed on drugs to treat orphan disease conditions.

Study Designs

An appropriate experimental design is important in being able to answer questions about drug safety and efficacy. The experimental design uses different groups of subjects (i.e., some groups who receive treatment and control groups who receive no treatment, an alternative treatment, or a combination of both) and assigns subjects randomly to treatment or control groups. Treatment groups and control groups do not differ in terms of baseline characteristics or demographics. If the subjects are different, variability is introduced and it becomes more difficult to determine a treatment effect. The examples in the following paragraphs illustrate selected research designs.

A *quasi-experimental* design would be a comparison of intermittent intravenous (IV) device patency of those hospitalized patients who received heparin flushes and those who

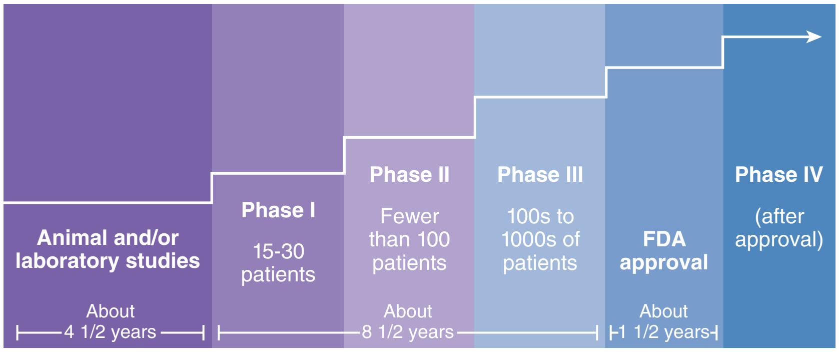

FIGURE 10–2 Clinical trials process.

received saline flushes. This study would have a nonmatched comparison group but no random assignment to a treatment group. Such quasi-experimental designs may contribute valuable information but ultimately lack the power to ascribe *cause*, because the variables are uncontrolled and potentially influential. Ethical decisions do not permit the use of this experimental design in all situations. For example, an experimental study to determine whether nicotine causes cancer would be unethical because individuals would have to be exposed to a carcinogenic substance. However, it might be possible to use an already-exposed group (smokers) as a comparator.

A researcher designs a study to show the effect of the independent variable (the drug) on the dependent variables (clinical responses or reactions). Intervening variables are specific to the research question and may include age, sex, weight, disease and its state of severity, diet, and the subject's social environment. It is important to control for as many of the intervening variables as possible to make it easier to determine whether there is a drug effect. Controlled treatment groups in drug research trials can receive no drug; a different drug; a **placebo** (pharmacologically inert substance); or the same drug with a different dose, route, or frequency of administration. A control group receiving a different drug is called an **active control.** In some cases, such as cancer treatment, it would not be ethical to use a placebo as a control.

A *crossover* design uses each subject in several different situations. In the first instance, the experimental group receives the drug and the control group receives an alternative form of treatment or no treatment. Then both groups receive no therapy. Finally, the experimental group receives the control form of therapy and the control group receives the drug. In this design, the subject serves as his or her own control.

The researcher wants to generalize the findings from the sample of subjects to the larger target population, such as all women with breast cancer. A statistical method called *probability sampling* (subjects are randomly selected from the entire population) is typically used to provide relative confidence in the generalization of findings.

In a *matched-pair* design, the researcher identifies several variables that may influence the outcome such as age, weight, or family history; the subjects are matched for these variables. One of the pair is randomly assigned to the experimental group and the other to the control group. A less effective technique is nonrandom assignment to treatment group.

The **double-blind** technique is a powerful tool wherein neither the health care provider nor the subject knows whether the subject is receiving the experimental or control form of therapy. In **triple-blind** studies, a researcher other than the prescribing health care provider collects data and is also unaware of the subject's treatment group. In a **single-blind** study, only the subjects are unaware of which group to which they are assigned. An **open-label study** indicates that all parties (data collectors, prescribing health care provider, and subject) know the treatment group assignment. The double-blind and triple-blind techniques are preferred for drug research, because those involved in the study are not aware of the subject's treatment group, thereby removing a source of bias.

Nurse's Role

The nurse has a pivotal role in drug clinical trials. The research and development process for drug research requires the multifaceted roles of professional nursing practice. Nurses must first consider their own thoughts, feelings, and beliefs about clinical trials. The nurse is both the patient and family advocate and the liaison between the patient, the health care provider, and the research nurse responsible for the specific protocol. Thorough and timely communication is essential in all aspects of the nurse's role. Nursing involvement is pivotal to the successful completion of clinical trials.

Asking relevant questions about informed consent and risk-to-benefit ratio is a major role of the nurse. Refer to the website for the Health Insurance Portability and Accountability Act (HIPAA) for implications for clinical trials (e.g., consent and privacy issues). Awareness of initial indicators of change in the patient and prediction of increased risk for adverse drug reaction are also dimensions of professional nursing practice.

Nursing responsibilities related to the specific research or clinical trial span the nursing process. Critical to the assessment phase are the recruitment and assessment of study subjects; a thorough understanding of the protocol, including inclusion and exclusion criteria for subjects; validity and reliability of measurement instruments; ongoing teamwork; and communication with the health care providers and sponsors.

Nursing input is important in the budget negotiations of the clinical trial as well as staff education on protocol requirements. Protocol guidelines are an essential component of staff education with special attention to ensuring that the subject's consent is "informed consent" obtained by the health care provider. The nurse is an ongoing resource when subject and family questions arise.

Protocol-based nursing implementations include comprehensive screening of subjects and monitoring parameters per protocol with relevant and timely communication with the entire health care team. Documentation on all predetermined components throughout the clinical trial is mandatory, including input from study subjects.

During the evaluation phase, the nurse's role involves examining the research statement or question. In addition, it considers elements such as: Are the conclusions valid and data-based? Are the findings clinically significant?

Nursing Process
Patient-Centered Collaborative Care

Clinical Drug Trials

Assessment

- Explore own beliefs about clinical trials.
- Recruit subjects.

- Assess protocol.
- Demonstrate thorough knowledge of all inclusion/exclusion criteria for subjects (see Box 10-1).
- Articulate observations and concerns to health care providers and sponsors/pharmaceutical company.
- Communicate need for drug to address a specific need with the appropriate individuals.

Planning

- Develop fact sheet of protocol guidelines.
- Educate involved staff about protocol requirements.
- Provide input into budget negotiations.
- Coordinate personnel and budget, including office visits, special tests, and laboratory work.
- Ensure that subject consent is informed (see Box 10-2 and Figure 10-1).
- Respond to subject's questions.

Nursing Interventions

- Screen subjects accurately and thoroughly based on established protocol.
- Adhere to protocol guidelines, including administration of drug.
- Monitor selected parameters. Observe and report toxicities promptly.
- Collect all data required by the sponsor (e.g., drug company).
- Communicate information in a complete, concise, accurate, and timely manner to the principal investigator and sponsor.
- Document data in a clear and timely manner.
- Record subjects' own evaluation; seemingly unrelated responses may be significant. At times, a drug is actually marketed for a different indication than the original testing.
- Report all adverse effects, including deaths, to physician, sponsor, Institutional Review Board, and FDA, whether or not the cause of death is drug related.

Cultural Considerations

- Be alert to specific side effects in selected drug groups from patients of different ethnic backgrounds (e.g., African Americans and their side effects from tricyclic antidepressants).
- Use an interpreter when necessary, preferably from the same ethnicity and gender, especially for sensitive and anxiety-raising topics.
- Depending on patient's background, include the extended family in the teaching and support system.

Evaluation

- Was the research design appropriate and maintained?
- Are the conclusions valid and based on data?
- Are the clinical findings significant?

NCLEX STUDY QUESTIONS

1. The nurse in the clinical research setting is knowledgeable about ethical principles and protection of human subjects. What principle is demonstrated when ensuring the patient's right to self-determination?
   a. Beneficence
   b. Autonomy
   c. Justice
   d. Informed consent
2. The research nurse is meeting with a patient and, based on the assessment, determines that the patient meets the criteria. The patient agrees to participate in the clinical trial. The nurse advises the patient that which member of the health care team has the responsibility to explain the study and respond to questions?
   a. Registered nurse
   b. Pharmacist
   c. Research associate
   d. Health care provider
3. The clinical research nurse knows that only a small proportion of drugs survives the research and development process. An appreciation of the process and associated costs grows when the nurse is aware that approximately one in how many potential drugs is actually used in clinical situations?
   a. 100
   b. 1000
   c. 10,000
   d. 100,000
4. The nurse is interviewing a patient in a Phase I clinical trial. Which patient statement indicates an understanding of this trial phase?
   a. "I am doing this to be sure this drug is safe."
   b. "I am doing this to be sure this drug is efficacious."
   c. "I hope this drug has no side effects."
   d. "I can be part of demonstrating a cure."

5. The nurse is reviewing the protocols associated with a triple-blind study. The nurse understands that this technique is preferred in clinical trials because it removes which factor?
   - a. Knowledge
   - b. Conflicts
   - c. Prejudice
   - d. Bias
6. The foundation of clinical trials, Good Clinical Practice (GCP) is a helpful resource for nurses. The nurse is correct in choosing GPC as a reference for standards in which areas? (Select all that apply.)
   - a. Design and performance
   - b. Monitoring and auditing
   - c. Analyses
   - d. Reporting
   - e. Outcomes evaluation
7. The nurse has an important role in working with patients on aspects of care that require informed consent. The patient and the nurse must be aware of the dimensions of informed consent. Which dimensions are included? (Select all that apply.)
   - a. Protection of subjects from harm
   - b. Promotion of finding cure of disease
   - c. Protection of patient's self-determination
   - d. Promotion of patient's educated decision making
   - e. Promotion of individual autonomy
8. The nurse researcher reviews the proposed informed consent form for a future clinical trial. The nurse expects to find which in the document? (Select all that apply.)
   - a. Description of benefits and risks
   - b. Identification of related drugs, treatments, and techniques
   - c. Description of outcomes
   - d. Statement of compensation for participants, if any
   - e. Description of serious risks
9. The nurse knows that the patient should be informed about available alternatives and consequences. What ethical principle does this describe?
   - a. Respect for persons
   - b. Veracity
   - c. Justice
   - d. Beneficence

Answers: 1, b; 2, d; 3, c; 4, a; 5, d; 6, a, b, c, d; 7, a, c, d, e; 8, a, b, d, e; 9, a.

UNIT II

A Nurse's Perspective of Pharmacology

The steps of the nursing process are described in Chapter 11, The Nursing Process in Patient-Centered Pharmacotherapy. Patient collaboration, also discussed in Chapter 11, is essential to promoting patient and family understanding of and adherence to drug therapy.

Chapter 12, Safety and Quality in Pharmacotherapy, provides information related to the medication culture of safety, including the rights of drug administration and the Quality and Safety Education for Nurses (QSEN) initiative. Chapter 13, Medication Administration, contains basic learning material for the administration of medications. It describes drug orders, drug distribution, drug charts, drug administration guidelines, and drug administration routes (with illustrated parenteral sites).

Chapter 13 and Unit III are recommended for drug administration and calculation in place of a nursing fundamentals text or a drug calculation text.

- Unfolding Case Studies

OBJECTIVES

- Discuss QSEN and the Guiding Principles for Patient Engagement in relation to medication safety.
- Differentiate the steps of the nursing process and their purpose in relation to drug therapy.
- Develop patient-centered goals.
- Discuss at least eight principles for health teaching related to drug therapy plans.
- Describe at least six culturally sensitive health teaching tips.
- Analyze the nurse's role related to drug therapy plans.

Nurses have a significant role in the management and delivery of safe drug therapy. Influences on this role include technology, increased longevity of populations in general, and survival of persons with multiple and varied biopsychosocial needs. Variables in drug therapy are numerous and, at times, unknown. The nurse is most often the one person who follows the patient most closely and the one who is first to assess the patient's response to drugs. The nurse applies knowledge of pharmacology to anticipate drug responses in the individual patient.

This chapter explores the use of the nursing process as it relates to drug therapy and patient education about pharmacotherapy. Careful attention to each phase of the process fosters the patient's success with the prescribed medication regimen. Initiatives such as Quality and Safety Education for Nurses (QSEN) and the Guiding Principles for Patient Engagement are resources to help nurses ensure and advocate for patient-centered collaborative care.

The overall goal through all phases of QSEN is to prepare future nurses with the knowledge, skills, and attitudes necessary to improve the quality and safety of the health care systems in which they work.

The QSEN competencies are as follows:

1. Patient- and family-centered care: Recognize the patient as the source of control and full partner in providing compassionate and coordinated care based on respect for patient preferences, values, and needs.

2. Collaboration and teamwork: Function effectively in nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality patient care.
3. Evidence-based practice: Integrate best current evidence with clinical expertise and patient/family preferences and values for delivery of optimal health care.
4. Quality improvement: Continuously improve the quality and safety of health care systems by using data to monitor outcomes of care processes and improvement methods to design and test changes.
5. Safety: Minimize risk of harm to patients and providers through both system effectiveness and individual performance.
6. Informatics: Use information and technology to communicate, manage knowledge, mitigate error, and support decision making.

This chapter focuses on patient- and family-centered care, and Chapter 12 offers additional information on safety in pharmacotherapy. QSEN competencies are also integrated throughout the book and are highlighted in special features such as Safety: Preventing Medication Errors boxes and High-Alert Drug icons. Patient-centered collaborative care is demonstrated in each nursing process.

Guiding Principles for Patient Engagement are core principles to support health care providers in their practice of patient-centered, quality care. These principles were developed by the Alliance for Quality Care (NAQC) and supported by the Robert Wood Johnson Foundation with the aim of "patient relationship as the cornerstone of patient safety and quality."

The core principles address the dynamic partnership among patients, their families, and the providers of their health care, confidentiality, mutual responsibilities and accountabilities, levels of engagement, advocacy, respecting boundaries, appreciation of patient's rights, mutuality, and health care literacy, and acknowledgment and appreciation of diverse backgrounds.

Both QSEN and the Guiding Principles for Patient Engagement assert principles that are foundational to patient-centered practice and safety in pharmacotherapy.

NURSING PROCESS: PATIENT-CENTERED COLLABORATIVE CARE

The phases of the nursing process are assessment, nursing diagnosis, planning, implementation (nursing interventions), and evaluation. Each phase is dependent on the preceding phase; sometimes revisiting a preceding phase is required. The phases are discussed as each relates to health teaching in drug therapy.

Assessment

The **assessment** phase of the nursing process is characterized by the systematic validation and documentation of information. Assessments are made throughout the nursing process. Assessment is particularly important because the data provided by the assessment form the basis on which nursing diagnoses are made and care is planned, implemented, and evaluated. Data collection must include both subjective and objective information.

Subjective Data

Subjective data are symptoms described by and apparent to the patient. The following components are reflective of subjective data related to the medication regimen:

- Current health history, including any problems with swallowing
- Patient symptoms
- Current medications, including over-the-counter (OTC) drugs, herbal remedies, and nutritional supplements
  - Dosage, frequency, and route of all drugs, and prescribing health care provider, if any
  - Patient knowledge about drug, its side effects, and reason drug is taken
  - Patient adherence with regimen and reasons for deviations (Were prescriptions filled and finished? Are deviations based on valid data/rationale and clinically sound?)
  - Patient expectation and perception of drug effectiveness
  - Patient knowledge about what effects or drug reactions to report to health care provider
  - Drug allergies or reactions both past and present; also reactions to food and dye
  - Use of tobacco products, alcohol, caffeine, and recreational drugs, including frequency and duration of use
- Past health history
  - Past illnesses, major injuries, drug therapy
  - Mental status
  - Medications saved from previous use, reason for saving them, and expiration date
- Patient's environment
  - Home safety (stairs, lighting, rugs, smoke detectors, supplies) and neighborhood safety (lighting, sidewalks) to meet patient's and family's specific needs.
  - Patient's language and communication needs (including language of origin)
  - Patient's ability and readiness to read and follow instructions from the health care provider and the pharmacy
  - Patient knowledge of specific drug storage requirements, if any
  - Availability, willingness, and psychomotor ability to administer or assist in the administration of medications; capability for activities of daily living (This information is essential for third-party payment for continued home visits or for admission to an extended care facility.)
  - Household members (neighbors and friends and their roles, if possible); ages of household members
  - Learning style preferences
  - Readiness to learn

  - Dietary patterns, cultural and economic influences, safety
  - Financial resources or limitations (drugs can be expensive)

Remember: Patients, even those who do not intend to withhold information, do not always share everything about their medications. Therefore, in addition to asking about prescription drugs, ask specifically about vitamin and mineral supplements, herbal supplements, all contraceptives, and OTC drugs. Identify caffeine and nicotine use, and include questions about use of skin patches; laypersons often fail to see patches as a mechanism of drug administration. Home health nurses should ask to see the contents of the medicine chest at home (or other storage area for medications) and should ask if the patient practices pill-splitting as a cost-saving measure and whether a pharmacist is consulted. Based on the response, appropriate teaching can be initiated.

Objective Data

Objective data are signs that are measured and detected by another person. The following components are reflective of objective data related to the medication regimen:

- Physical health assessment: Limitations in gross- and fine-motor control; hand and joint range of motion; hand and finger muscle strength; visual impairment; and ability to read labels and correctly measure dosages.
- Laboratory test results and diagnostic studies: Baseline data are essential for future comparisons.

Data collection should provide additional information about the patient's symptoms and should also target those organs most likely to be affected by drug therapy. For example, if a drug is nephrotoxic, the patient's creatinine clearance should be assessed. Assess major body systems for any signs of reaction to or interaction of drugs or ineffectiveness of therapy.

Based on assessment data, the nurse must identify high-risk patients (those likely to have adverse reactions). The patient's health history, physical assessment, and laboratory test results are sources of these data.

Enhancing patient adherence with the drug therapy regimen is an essential component of health teaching. The patient and family response to the following three questions provides the nurse with critical information unique to each patient's teaching situation:

1. What things help you take your medicine as prescribed?
2. What things prevent you from taking your medicine as prescribed?
3. What would you do if you forgot to take a dose of medication?

Frequently cited factors for nonadherence include forgetfulness, knowledge deficit, side effects, low self-esteem, depression, lack of trust in the health care system, family problems, language barriers, high cost of medications, anxiety, value systems (e.g., religion), and lack of motivation. Drug shortages create additional concerns because patients may be dissatisfied with the effectiveness, cost, and side effects of alternative drug choices.

The patient's attitudes and values about taking medication are very important considerations when determining the patient's and family's readiness to learn. These attitudes and values should be considered when planning interventions to support the patient's decision to adopt healthy behaviors related to taking medications. The patient's social support system is emphasized. This special support system, unique to the individual, may be composed of persons who assist in preparing medications, organizing pills, and ordering medications, and can be alert to side effects—all actions that promote taking medication as prescribed and notifying the health care provider if a problem arises.

Nursing Diagnosis

A **nursing diagnosis** is made based on the analysis of the assessment data. Abnormal data collected during the assessment serve as the defining characteristics (for an actual problem) or risk factors (for a high risk for a problem) to support the appropriate nursing diagnosis. More than one applicable nursing diagnosis may be generated. The registered nurse formulates nursing diagnoses and uses them to guide the development of a care plan.

Common nursing diagnoses related to drug therapy include the following:

- Pain (acute or chronic) related to hesitancy in taking prescribed pain medications because of fear of addiction
- Acute confusion related to adverse reaction to medication
- Ineffective health maintenance related to not receiving recommended preventive care
- Deficient knowledge related to effects of anticoagulant medication on clotting mechanism
- Noncompliance related to forgetfulness
- Risk for injury related to side effects of drug (e.g., dizziness, drowsiness)
- Ineffective self-health management related to lack of finances or health care coverage to purchase medications
- Readiness for enhanced knowledge related to medication schedule and medication side effects

Use of these nursing diagnoses is beneficial to the patient because it facilitates the development of an individualized care plan for each patient. Note: To strengthen comprehensiveness of nursing diagnoses, consider using well/health promotion diagnoses.

Planning

The **planning** phase of the nursing process is characterized by **goal setting** or expected outcomes. Goals are patient centered, describe the specific activity, and include a time frame for achievement/reevaluation. Planning also includes development of nursing interventions that will be used to assist the patient to meet the goals. Effective goal setting has the following qualities:

- Is patient centered (accomplished through collaboration with the patient and/or family to develop goals that focus on patient outcomes)

- Clearly states the expected change: realistic, measurable, with reasonable deadlines
- Is acceptable to both patient and nurse (dependent on patient's decision-making ability)
- Is shared with other health care providers and with patient's family or caregiver
- Identifies components for evaluation

Examples of well-written comprehensive goals are (1) patient will independently administer prescribed dose of insulin by end of the fourth session of instruction; (2) patient will prepare a medication recording sheet that correctly reflects prescribed medication schedule within 3 days.

Implementation and Nursing Interventions

The **implementation** phase is the part of the nursing process in which the nurse provides education, medication administration, patient care, and other interventions necessary to assist the patient in accomplishing the established goals. In most practice settings, administration of drugs and assessment of drug effectiveness are also important nursing responsibilities. (See Chapters 12 and 13 for more information.)

Patient Teaching

Readiness to learn is paramount. Patient education is an ongoing, complex, multifaceted process and a dynamic interaction between nurse and patient in which both communicate information and emotions. Teaching is focused on health promotion and/or a specific skill to optimize patient health status. Teaching is more effective in an environment free of distractions, and the information should be tailored to the patient's interests and level of understanding. Assessment data suggest the complexity, number, and length of teaching sessions that may be required. Be sensitive to the patient's motivation to learn, attention span, and level of frustration. Readiness to learn is paramount. Readiness should be assessed first, before information is presented to the patient. Use a positive approach—for example, "This narcotic is usually effective for the relief of the type of pain you have." Be an active listener and observer.

Assessment data guide the nurse to the appropriate persons to be included. The inclusion of a family member or friend in the teaching plan is an excellent idea. This person may (1) act as a psychological support, (2) actually administer all or part of the drug therapy, (3) observe the effectiveness and side effects of the drug therapy, and (4) implement other changes such as food shopping or instituting new methods of food preparation. Provide simple written materials appropriate for individual patient needs. The patient and family must have the appropriate information (e.g., telephone number, email address) to reach the health care provider for questions and concerns. Health care providers should be available to provide timely responses.

With patient teaching being critical to the success of pharmacotherapy, it might be helpful for the nurse to use an outline format for patient education. Suggested topics related to pharmacotherapeutics include the following:

- *General.* Instruct the patient to take the drug as prescribed. Adherence is of utmost importance because discontinuing the drug before the course is completed may result in relapse or future ineffectiveness of the drug. Do not adjust dose, frequency, or time of day taken unless directed by the health care provider. Advise women contemplating pregnancy to check first with their health care provider before taking prescription or OTC medications and herbal products. Advise patients to consult with their health care provider about laboratory tests such as liver enzymes, blood urea nitrogen (BUN), creatinine, and electrolytes, which should be monitored when taking selected drugs.
- *Self-administration.* The patient's psychomotor skills and abilities are critical. Based on assessment of these, consider recommendations for modifications as appropriate. Reassess psychomotor skills on an ongoing basis. Instruct the patient on the administration of the drug according to the prescribed route: eyedrops or nose drops, subcutaneous insulin injections, suppositories, swish-and-swallow suspensions, and metered-dose inhalers with and without spacers. Include demonstration and return demonstration in the instructions when appropriate. Give written instructions for the sighted patient and audio instructions for the visually impaired. Teach more than one person when possible, because this aids in reinforcement and retention of information. It also provides a "backup" if the patient is unable to self-administer the drug.
- *Diet.* Advise patients about foods to include in their diet and foods to avoid. Many foods interact with certain drugs. Depending on the nature of the interaction, certain foods have the ability to decrease drug absorption, increase the risk of drug toxicity, or create other problems that make them an important safety concern.
- *Side effects.* Instruct the patient to report unusual symptoms immediately to the designated health care provider—usually a nurse, physician, or pharmacist. Give the patient instructions that help minimize any side effects (e.g., avoiding direct sunlight when there is risk of photosensitivity or sunburn). Advise the patient of any expected changes in the color of urine or stool. Advise the patient who has dizziness caused by orthostatic hypotension to rise slowly from a sitting to a standing position.
- *Cultural considerations.* A **culturally sensitive** nurse is one who has an awareness of the implications of culture for the patient and family. Be alert to patient and family cultural expectations. For example, the patient may not view time as important, which may affect the patient's adherence to taking medications at specific times during the day. The nurse applies knowledge of cultural considerations to individualize a teaching plan (Box 11-1). Refer to Chapter 3 for more information; cultural content is also found in the Nursing Process boxes in each chapter.

A teaching plan with interventions that involves stimulation of several senses and active participation by the patient enhances learning. Inclusion of return demonstrations by the

BOX 11-1 CULTURALLY SENSITIVE HEALTH TEACHING TIPS

- Flexibility in timing appointments may be necessary for those who have a circular sense of time rather than a linear sense of time.
- The nurse should consider whether appointments are something deemed culturally relevant.
- Discuss the ethnicity of the interpreter as well as the language desired when translation is needed. Provide an interpreter with the same ethnic background and gender if possible, especially with sensitive topics. Speak clearly and slowly, giving time for translation. Ask family members to assist with translation only if an interpreter is not available.
- Use videos and literature in the patient's preferred language to enhance adherence to health interventions when language and cultural barriers exist.
- Use simple and clear instructions that employ user-friendly terminology at the fourth-grade level. Avoid use of acronyms and abbreviations. Allow adequate time for information processing; failure to do this may result in an inaccurate response or no response. Allow time response to questions, especially for patients who have language barriers.
- Ask open-ended questions, and have patients demonstrate, rather than verbalize, their understanding of treatments. Because politeness and "saving face" may be important, do not assume that a positive response means a definite yes.

BOX 11-2 POINTS FOR PATIENTS AND FAMILIES TO REMEMBER

Take medication as prescribed by your health care provider. If you have questions, call.

Keep medication in the original labeled container, and store as instructed.

Keep all medicines out of the reach of children. Remind grandparents and visitors to monitor their purses and luggage when visiting.

Before using any over-the-counter (OTC) drugs, check with your health care provider. This includes use of aspirin and laxatives. Consider asking the pharmacist before buying or using a product.

Bring all medications with you when you visit the health care provider.

Know the purpose of each medication and under what circumstances to notify the health care provider.

Do not drink alcoholic beverages around the time you take your medications. Alcohol is absolutely contraindicated with certain medications. Alcohol may alter the action and absorption of medications.

Be aware that smoking tobacco also alters the absorption of some medications (e.g., theophylline-type drugs, antidepressants, pain medications). Consult your health care provider or pharmacist for specific information.

patient and others, when applicable, gives the nurse important feedback about the patient's learning and gives the patient confidence in carrying out the regimen or selected aspects of the regimen. Additional teaching tips include the following:

- Establish a trusting relationship.
- Teach patient and family the importance of bringing a medication list (including OTC, herbal, and vitamin products) or medications to all health care provider appointments in all settings.
- Provide written instructions in addition to other teaching aids.
- Use colorful charts and graphs.
- Consider using a variety of media, including audio and video.
- Encourage questions from patient and family; provide time for this. Do not rush.
- Use materials and language appropriate to patient's level of understanding; supply patient medication information sheets in different languages and appropriate reading levels.
- Space instruction over several sessions, if appropriate.
- Review community resources related to patient's nursing and medical diagnoses.
- Collaborate with patient and family and other health care staff and agencies to mobilize resources to meet patient's needs.
- Identify patients at risk for noncompliance with regimen. Alert health care provider and pharmacist so they can develop a plan to minimize the number of drugs and times administered.
- Evaluate patient's understanding of medication regimen on a regular basis.
- Empower patient to take responsibility for managing medications.

The use of teaching drug cards is helpful. These cards provide information about a specific drug or drug group. They may be developed by the health care provider or obtained from drug manufacturers. Helpful components for the teaching drug cards include name of the drug; reason for taking the drug; dosage; specific times to take the drug; possible side effects; possible adverse effects and when to notify health care provider; and specific things that should or should not be done while taking the medication (e.g., do not crush, take with food)

Group classes are useful for patients with certain diagnoses or who require certain drugs. A variety of formats can be developed. Be creative!

General points to remember and tips for successful patient education are presented in Box 11-2.

Many people take multiple medications simultaneously several times each day, which presents a challenge to the patient, his or her family, and the nurse. This complex activity of taking medications can be segmented into several simple tasks, including the following:

- Preparation of 1 day's or 1 week's supply of medication. The day's medication can be put into one container. Sorting of a day's supply allows the patient and the nurse to see at a glance what medications have and have not been taken. Keep in mind that a missing pill may have been dropped and not actually taken. A variation in accomplishing this task is to take a day's medication and sort or package the pills according to the time each is to be taken. Multi-compartment dispensers (available at drugstores) or an egg carton may help some patients sort their drugs.

- A recording sheet may be helpful. The patient or a family member marks when each medication is taken. The sheet is designed to meet the patient's individual needs; for example, the time can be noted by the patient or can be entered beforehand, with the patient marking when each dose is taken. A generic format follows.

	DOSAGE	DAY OF WEEK						
MEDICATION	(mg DAILY)	S	M	T	W	TH	F	S
captopril (Capoten)	12.5							
digoxin	0.25							
furosemide (Lasix)	40							

Alternatives to recording sheets are also available. Alarm reminder devices may be helpful to some patients. A combination of daily supply and recording may be helpful. Consider color-coding. Visual acuity, manual dexterity, and mental processes have a major effect on which system works best for each patient.

Throughout the teaching plan, the nurse promotes patient independence (e.g., self-administering medications, safely storing medications, ordering medications). The nurse should not lose sight of the goals or outcomes and become immersed in the intervention process (e.g., teaching a patient with short-term memory loss). Box 11-3 presents items for a checklist for health teaching in drug therapy.

BOX 11-3 CHECKLIST FOR HEALTH TEACHING IN DRUG THERAPY

- Comprehensive drug use and health history
- Reason for medication therapy
- Expected results
- Side effects and adverse reactions
- When to notify health care provider or pharmacist
- Drug-drug, drug-food, drug-laboratory, and drug-environment interactions
- Required changes in activities of daily living (ADLs)
- Demonstration of learning; may take several forms, such as listening, discussing, or return demonstration of psychomotor skills (insulin administration)
- Medication schedule, associated with ADLs and drug level of action as appropriate
- Recording system
- Discussion and monitoring of access to financial resources, medication, and associated equipment
- Development and support of backup system
- Community resources available

Evaluation

In the **evaluation** phase of the nursing process, the nurse determines how well goals are obtained. Nursing interventions are revised and teaching is focused to improve goal attainment if goals are not met.

The specific outcomes must be articulated with the patient and significant others to determine if they have been met. Additional data may be needed to assess if adherence to the drug regimen is not done. For example, patients may be denying or minimizing their diagnosis, financial problems may prevent timely prescription refill, or vision or physical limitations may inhibit administration of the drug. When the evaluation of a goal will occur depends on the time frame specified in the statement of the goal. Evaluation should be ongoing and related to progress as well as to attainment of the final goal.

If goals are not met, the nurse, in collaboration with the patient or family, must determine the reasons and revise the plan accordingly. This includes additional assessment data and the setting of new goals.

To complete the care for any current patient, review with the patient and family the need for follow-up care, if required, and refer the patient to community resources as necessary.

CRITICAL THINKING CASE STUDY

MZ, a 66-year-old man, lives in a two-story home in rural Vermont. He complains of shortness of breath, wheezing, and cough, primarily at night. MZ takes multiple asthma medications, and one of them (albuterol) is administered via nebulizer. He is 5 feet 11 inches tall and weighs 118 pounds. He admits to loss of appetite and reports, "I eat enough to keep going."

1. What are the most relevant nursing diagnoses for this patient?

NCLEX STUDY QUESTIONS

1. During a medication review session, a patient says, “I just do not know why I am taking all of these pills.” Based on this piece of subjective data, which diagnosis will the nurse identify?
   a. Risk for injury
   b. Deficient knowledge
   c. Risk for aspiration
   d. Anxiety
2. The nurse is developing goals in collaboration with a patient. Which is the best goal statement?
   a. The patient will self-administer albuterol by tomorrow.
   b. The patient will self-administer the prescribed dose of albuterol by the end of the second teaching session.
   c. The patient will independently self-administer the prescribed dose of albuterol by the end of the second teaching session.
   d. The patient will organize her medications by tomorrow.
3. When developing an effective medication teaching plan, which component will the nurse identify as most essential?
   a. Provide written instructions.
   b. Establish a trust relationship.
   c. Use colorful charts.
   d. Review community resources.
4. When developing an individualized medication teaching plan, which topics will the nurse include? (Select all that apply.)
   a. Importance of adherence to the prescribed regimen
   b. How to administer medication(s)
   c. What side/adverse effects to report to the health care provider
   d. Foods that must be eaten
   e. Follow-up laboratory tests, if needed
5. The Guiding Principles for Patient Engagement are most important for health care providers as they strive for which goal?
   a. Nurses to focus care on quality and safety
   b. Confidentiality as determined by the patient
   c. All health care providers to have patient relationship for cornerstone of safety and quality
   d. Patient advocacy
6. The QSEN focus on safety is best exemplified by which competency?
   a. Patient advocacy
   b. Technology-enhanced medication administration
   c. Quality improvement
   d. Patient-centered collaborative care
7. Which teaching strategy is most likely to succeed in health teaching with the patient and family?
   a. Have patient verbalize understanding
   b. Have patient answer closed-ended questions
   c. Have patient demonstrate information
   d. Have patient identify pill by color

Answers: 1, b; 2, c; 3, b; 4, a, b, c, e; 5, c; 6, d; 7, c.

CHAPTER 12

Safety and Quality in Pharmacotherapy

evolve WEBSITE

- Key Points
- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Discuss the QSEN initiative related to safe administration of medications.
- Describe the "five-plus-five" rights of medication administration.
- Analyze safety risks for medication administration.
- Discuss safe disposal of medications.
- Discuss high-alert drugs and strategies for safe administration.
- Describe application of safe practices when ordering medications on the Internet.
- Discuss safety bases of pregnancy categories.
- Apply the nursing process to safe administration of medications.

Nearly 4 billion prescriptions were written in the United States in 2010, according to the IMS Institute for Healthcare Informatics. Prescription medicines, over-the-counter (OTC) drugs, or dietary supplements are used by 80% of adults. The Institute for Safe Medication Practices reports that 33% of adults take at least five medications daily.

Medication errors are the most frequent malpractice claims against hospitals and nurses, costing about $5000 per error. More than $3 million is awarded (on average) by the courts for serious errors. The cost of the patient and family suffering is not calculable.

The focus of this chapter is the Quality and Safety Education for Nurses (QSEN) initiative as it relates to safe medication administration and prevention of medication-related errors. The six QSEN competencies focus on patient/family–centered care, collaboration and teamwork, evidence-based practice, quality improvement, safety, and informatics. (Refer to Chapter 11 and the QSEN website, *www.qsen.org*.)

"FIVE-PLUS-FIVE" RIGHTS OF MEDICATION ADMINISTRATION

The rights of medication administration are the foundation for medication safety. The nurse following the original five rights of medication administration will give (1) the *right patient* the (2) *right drug* (3) in the *right dose* via (4) the *right route* at the (5) *right time*. Experience shows that five additional rights are essential to professional nursing practice: (1) *right assessment,* (2) *right documentation,* (3) *patient's right to education,* (4) *right evaluation,* and (5) *patient's right to refuse.*

The **right patient** determination is essential. The Joint Commission (TJC) requires two forms of identification before administration of the medication. Some patients are unable to respond or answer to any name, so the nurse must verify patient identification each time he or she administers a medication.

Nursing implications include the following:

- Verify the patient by checking the patient's identification bracelet. Some facilities put the patient's photo on the health record.
- Distinguish between two patients with the same first or last name; have warnings highlighted in a bright color on identification (ID) tools such as a med card, bracelet, or Kardex.
- Some institutions have ID bracelets coded for allergy status. Be aware of whether such a policy exists at your institution.
- When patients do not wear ID bracelets (e.g., in schools, occupational health departments, outpatient departments, or health care provider offices), the nurse must accurately identify the individual by other means when administering a medication.

The nurse must be sure that the **right drug** is administered. Medication orders may be prescribed by any licensed health care provider (HCP) having authority from the state to prescribe drugs. These include a physician (MD), dentist (DDS), podiatrist (DPM), advanced practice registered nurse (APRN), or physician assistant (PA). In some health care settings, medical students write drug orders; these orders must be countersigned by an attending or staff physician or other prescribing health care provider before they are considered official. The law requires that handwritten prescriptions be written on a tamperproof prescription pad and filled by a pharmacist at a drugstore or hospital pharmacy. Depending on agency policy, drug orders may be written on order sheets and signed by the duly authorized person. A telephone order (TO) or verbal order (VO) for medication must be "read back" to the HCP as an accuracy check and cosigned by the prescribing health care provider within 24 hours. The nurse must comply with the institution's policy regarding a TO, which sometimes requires that two licensed nurses listen to and sign the order.

As part of the electronic health record (EHR), prescriptions may also be entered directly into the patient's record, electronically signed by the HCP, sent directly to the pharmacy, and recorded as part of the patient record. A strong safety feature of the EHR is the ability to identify untoward drug interactions with the patient's current drugs and the newly prescribed/ordered medications. The EHR has decreased medication errors by eliminating some opportunities for errors such as transcription errors.

The use of computerized order systems has added speed and a safety feature to the order process. Orders can be written from virtually any location and sent electronically. The computer will not process the order unless all necessary information is included. Because the order is computerized, illegible orders or signatures are prevented.

The components of a drug order are as follows:

- Date and time the order is written
- Drug name (generic preferred)
- Drug dosage
- Route of administration
- Frequency and duration of administration (e.g., × 7 days, × 3 doses)
- Any special instructions for withholding or adjusting dosage based on nursing assessment, drug effectiveness, or laboratory results
- Physician or other health care provider's signature or name if TO or VO
- Signatures of licensed staff taking TO or VO

Although the nurse's responsibility is to administer drugs as ordered, the drug order is incomplete and the drug should not be administered if any one of the components is missing. Clarification of a questionable order must be done in a timely manner. The health care provider is usually contacted, and the conversation content is documented. Nurses must know all of the components of a drug order and question any orders that are incomplete or unclear, give a dosage outside of the recommended range, or are contraindicated by patient allergy or laboratory test results. Nurses are legally liable if they give a prescribed drug and the dosage is incorrect or the drug is contraindicated for the patient's health status. Once the drug has been administered, the nurse becomes liable for the predicted effects of that drug.

The following is an example of a drug order and its interpretation:

1/1/14, 1010 Lasix 40 mg, PO, daily [signature]. (Give 40 mg of Lasix by mouth daily.)

To avoid drug error, the drug label should be read three times: (1) at the time of contact with the drug bottle/container or the prepackaged drug unit, (2) before measuring the drug, and (3) after measuring the drug. First dose, one-time, and "as needed" (PRN) medication orders should be checked against the original orders. Nursing interventions related to a drug order include the following:

- The nurse should be well versed in the patient's health history and previously performed assessments.
- Check that the medication order is complete and legible. If the order is not complete or legible, notify the nurse manager and health care provider.
- Know the patient's allergies.
- Know the reason the patient is to receive the medication.
- Check the drug label three times before administration of the medication.
- Know the date the medication was ordered and any ending date (e.g., for controlled substances and antibiotics and for limited or a specific number of doses). Some agencies have "automatic stop orders" that are generally facility specific. Examples of such orders include controlled drugs that need to be renewed every 48 hours, antibiotics to be renewed every 7 to 14 days, and cancellations of all medications when the patient goes to surgery.

The **right dose** refers to verification by the nurse that the dose administered is the amount ordered and that it is safe for the patient for whom it is prescribed. The right dose is based on the patient's physical status, including renal and hepatic function. Renal and hepatic function are important considerations because many drugs are cleared through the kidneys and metabolized by the liver. Patient weight is another important consideration in multiple contexts, such as pediatrics and many medical, surgical, and critical care situations. In most cases, the right dose for a specific patient is within the recommended range for the particular drug. Nurses must calculate each drug dose accurately (see Chapter 14).

Before calculating a drug dose, the nurse should have a general idea of the answer based on knowledge of the basic formula or ratios and proportions. Recheck the calculation of drug doses if a fraction of a dose or an extremely large dose is calculated. Consult a peer or a pharmacist whenever doubt exists.

The stock drug method and unit dose method are the two most frequently used methods to dispense drugs (Table 12-1). In the traditional **stock drug method,** the drugs are dispensed to all patients from the same containers. In the **unit dose method,** drugs are individually wrapped and labeled for single doses for each patient. The unit dose method, which is popular in many institutions and community settings, has reduced dosage errors because no calculations are required.

TABLE 12-1 DRUG DISTRIBUTION METHODS

STOCK DRUG METHOD	UNIT DOSE METHOD
Description	
Drugs are stored on unit and dispensed to all patients from the same container	Drugs are packaged in doses for 24 h by the pharmacy
Advantages	
Always available	Saves time for nurse; no dose calculation required
Cost-efficiency of large quantities	Billed for specific doses
	More accountability
	Less chance for contamination and error
Disadvantages	
Drug errors are more prevalent with multiple "pourers"	Potential delay in receiving drug
More risk of abuse by health care workers	Not immediately replaceable if contaminated
Less accountability for amount used; unable to track usage	More expensive
Increased opportunity for contamination (multiple pourers challenge aseptic/sterile status)	

Automated dispensing cabinets assist the nurse in correctly and quickly administering medications. This technology improves patient care by promoting accurate and quick access to medications, locked storage for all medications, and electronic tracking for controlled substances. Pharmacists can review orders using a link to the pharmacy information system and current clinical patient data, interface with other databases (e.g., the laboratory), and bar-code doses. Automation of medication administration saves time, decreases costs associated with the administration of medications, and allows the ability to automatically collect documentation information. An activity report menu is a useful feature. Flexible dose modes are available, including single-dose, multi-dose, and multiple medications.

Nursing interventions related to the right dose include the following:

- Calculate the drug dose correctly. When in doubt, recalculate the drug dose and check with another nurse. In many settings, the first nurse to administer the particular drug to the patient must calculate the dose according to the stated formulary doses and sign in the nurse's signature space once the safety parameter has been established. In some settings, two registered nurses (RNs) are required to check dosage for specific medications such as insulin and heparin.
- Check the American Hospital Formulary, the drug package insert, or other drug references for the recommended range of specific drug doses.

The **right time** is the time the prescribed dose is ordered to be administered. Daily drug dosages are given at specified times during a day, such as twice a day (b.i.d.), three times a day (t.i.d.), four times a day (q.i.d.), or every 6 hours (q6h), so that the plasma level of the drug is maintained at a

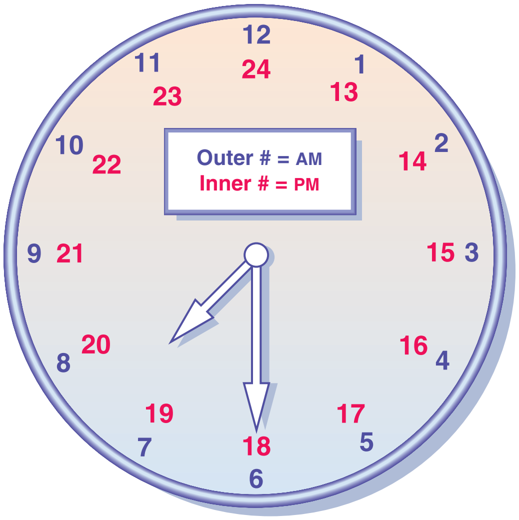

FIGURE 12–1 Military time.

therapeutic level. Every drug cannot be given exactly when ordered; therefore, health care agencies have policies that specify a range of times within which drugs can be administered before or after the appointed time. When a drug has a long half-life (t½), it is usually given once a day, although many depot preparations have a t½ of days. Drugs with a short t½ are given several times a day at specified intervals. Some drugs are given before meals, and others are given with meals or other food depending on the effect of the gastrointestinal (GI) environment on absorption of the drug.

Use of military time reduces administration errors and decreases documentation. Many nursing settings use military time, which is a 24-hour clock. See Figure 12-1 for military time in comparison with standard time. Nursing interventions related to the right time include the following:

- Administer drugs at the specified times (refer to agency policy).
- Administer drugs that are affected by food (e.g., tetracycline) 1 hour before or 2 hours after meals.
- Administer drugs that can irritate the stomach (gastric mucosa)—for example, potassium and aspirin—with food. Some medications are absorbed better after eating.
- Adjust the medication schedule to fit the patient's lifestyle, activities, **tolerances**, or preferences, as appropriate and if possible.
- Check whether or not the patient is scheduled for any diagnostic procedures such as endoscopy or fasting blood tests that contraindicate the administration of medications. Determine per policy if the medication should be given before or after the test is completed.
- Check the expiration date. Discard the medication or return it to the pharmacy (depending on policy) if the date has passed.
- Administer antibiotics at even intervals (e.g., q8h rather than t.i.d.) throughout a 24-hour period so therapeutic blood levels are maintained.

The **right route** is necessary for adequate or appropriate absorption. The right route is ordered by the health care provider and indicates the mechanism by which the medication enters the body. The more common routes of absorption include *oral* (by mouth): liquid, elixir, suspension, pill, tablet, or capsule; *sublingual* (under the tongue for venous absorption); *buccal* (between the gum and cheek); via feeding tube; *topical* (applied to the skin); *inhalation* (aerosol sprays); *instillation* (in nose, eye, or ear); *suppository* (rectal or vaginal); and five *parenteral* routes: intradermal, subcutaneous (subQ), intramuscular (IM), intravenous (IV), or intraosseous (IO).

Nursing interventions related to the right route include the following:

- Assess the patient's ability to swallow before administering oral medications; make sure that the patient is not NPO.
- Do not crush or mix medications in other substances without consulting a pharmacist or a reliable drug reference. Do not mix medications with sweet substances to trick children into taking them. Do not mix medications in an infant's formula feeding.
- If the medication is or must be mixed with another substance, explain this to the patient. For example, many children's medicines have flavor added (e.g., bubble gum– or banana-flavored antibiotics) to make them palatable.
- Use aseptic technique when administering drugs. Sterile technique is required with the parenteral routes.
- Administer drugs at the appropriate sites for the route.
- Stay with the patient until oral drugs have been swallowed.

The **right assessment** requires collection of appropriate data before administration of the drug. Examples of assessment data include apical heart rate before the administration of digitalis preparations or serum blood sugar levels before the administration of insulin.

The **right documentation** requires the nurse to immediately record the appropriate information about the drug administered. This includes (1) the name of the drug, (2) the dose, (3) the route (injection site if applicable), (4) the time and date, and (5) the nurse's initials or signature. Documentation of the patient's response to the medication is required with a variety of medications: (1) opioids (How effective was pain relief?); (2) non-opioid analgesics (How effective was pain relief?); (3) sedatives (How effective was relaxation?); and (4) antiemetics (Was nausea/vomiting decreased or eliminated?). Unexpected reactions to the medication (Was there any GI irritation or signs of skin sensitivity?) should also be documented. Patient responses are not necessarily verbal; they could be physiologic (e.g., Did blood pressure go down in response to an antihypertensive? Did LDL cholesterol go down in response to a statin?). Delay in charting could result in forgetting to chart the medication, and another nurse could administer the drug, assuming that the drug was not administered because it was not charted. Do not sign off medications before administration because the medication may not be administered to the patient for some reason. Graphic formats or computerized systems (Figure 12-2) assist in accurate and timely recording of drugs administered.

The **right to education** requires that patients receive accurate and thorough information about the medication and

how it relates to their particular condition. Patient teaching also includes therapeutic purpose, expected result of the drug, possible side effects of the drug, any dietary restrictions or requirements, skill of administration, and laboratory test result monitoring. This right is a principle of **informed consent,** which is the individual having the knowledge necessary to make a decision. An informed patient and family is critical to preventing medication errors.

The **right evaluation** refers to an appraisal of a drug's therapeutic and adverse effects. Evaluation in this context asks, "Did the medication do for the patient what it was supposed to do?" It is essential for the nurse's practice to evaluate the therapeutic effect of the medication as well as any side effects and adverse reactions. This evaluation is an important aspect of patient safety.

The patient has the **right to refuse** the medication. Patients can and do refuse to take a medication. It is the nurse's responsibility to determine, when possible, the reason for the refusal and, if the reasoning is not sound, to take reasonable measures to facilitate the patient's taking the medication. Explain to the patient the risk of refusing to take the medication, and reinforce the reason for the medication. When a medication is refused, the refusal must be documented immediately, and follow-up is always required. The nurse manager, primary nurse, or health care provider should be informed when the omission may pose a specific threat to the patient, and when a change is expected in the laboratory test values, such as with insulin and warfarin (Coumadin).

Consider all medication errors serious or potentially serious. A medication error may involve one or more of the following: administration of the wrong medication or IV fluid; the incorrect dose or rate; administration to the wrong patient, by the incorrect route, or at the incorrect schedule interval; administration of a known allergenic drug or IV fluid; omission of a dose; or discontinuation of medication or IV fluid that was not discontinued.

NURSES' RIGHTS WHEN ADMINISTERING MEDICATIONS

In addition to the rights of medication administration, there are six rights for nurses who administer medications. These rights provide an additional layer of safety by ensuring that the nurse has what is needed to provide safe medication administration.

The nurses' six rights are (1) the right to a complete and clear order; (2) the right to have the correct drug, route (form), and dose dispensed; (3) the right to have access to information; (4) the right to have policies to guide safe medication administration; (5) the right to administer medications safely and to identify problems in the system; and (6) the right to stop, think, and be vigilant when administering medications. Discussion of these rights can assist in increasing the safety of medication administration.

The *right to a complete and clear order* requires that the drug, dose, route, and frequency be ordered by the health care provider. Prescription orders entered directly into a computer ensure that the prescription is legible. However, the nurse must question the health care provider if the order is not complete or is unclear.

The nurse has the *right to have the correct drug, route (form), and drug dispensed.* Dispensing medications correctly is the role of the pharmacist. Automated medication administration systems may be programmed to allow nurses access to many kinds of medications, rather than the safer unit dose access.

The *right to have access to information* includes the right to expect current and readily accessible drug information (e.g., hospital formulary, nursing drug reference). This right is a must. Nurses are only to administer drugs with which they are knowledgeable.

Nurses have the *right to have policies to guide safe medication administration.* Health care administration's role is to provide the structure on which nurses administer drugs safely. In each facility, policies guide nursing practice. Not following policy or administering medication without policies is not acceptable and places nurses at risk for losing their nursing license.

The *right to administer medications safely and to identify problems in the system* encompasses nurses' right and responsibility to speak up when they are first aware of situations that impinge negatively on safe administration of medications. Nurses should be an advocate for safety in the health care setting.

Nurses have the *right to stop, think, and be vigilant when administering medications.* When unsure, nurses have the right and responsibility to stop and think, consult with other health professionals, and check their institution's policies. Safety is the basis for these actions.

CULTURE OF SAFETY

The Institute of Medicine (IOM) classic report of 1999, *To Err Is Human: Building a Safer Health Care System,* spurred work on identifying health care system changes to decrease errors. A medication error may be defined as "any preventable event that may cause or lead to inappropriate medication use or harm to a patient."

Possible causes of medication errors include dramatic increase in the number of drugs available; violation of the rights of nursing medication administration; lack of drug knowledge; memory lapses; transcription, dispensing, or delivery problems; inadequate monitoring; distractions; overworked staff; lack of standardization; equipment failures; inadequate patient history; and poor interdepartmental communication.

In response to the escalating number of medication errors causing human deaths and costing billions of dollars, in 2002 the FDA proposed a rule titled *Bar Code Label Requirements for Human Drug Products and Blood,* which has increased the prominence of this coding. At a minimum, the bar code contains the drug's national drug code that "uniquely identifies the drug, its strength, and its dosage form." A revision to this rule eliminates blood and blood products because they have had bar codes since 1985. Most staff embrace bar coding once they are proficient with its use. They note, however, that bar coding is a tool but not a substitute for critical thinking.

Computerized prescriber order entry systems interact with laboratory, pharmacy, and patient data. This integrated system of patient data is the basis for the success of bar coding. With bar coding, the patient's medication administration record (MAR), a part of the database that is encoded in the patient's wristband, is accessible to the nurse using a handheld device. After scanning the patient's wristband, the nurse sees the individual's MAR on the device. To administer a medication, nurses first scan the drug's bar code, then the number of the patient's medical record, and finally the nurse's own ID badge code. The patient's MAR is then updated accordingly. (Figure 12-3 shows a nurse scanning a patient's wristband.) The nurse receives verification on the handheld device of the five rights, warnings, and clinical alerts (e.g., drug is discontinued, drug is not ordered for patient).

Additionally, TJC has taken steps to prevent drug errors. As part of their National Patient Safety Goals, TJC announced in 2004 that all accredited organizations may no longer use selected abbreviations, acronyms, and symbols because they can be misinterpreted or misread. See Table 12-2 for this "Do Not Use" list, and see Table 12-3 for a list of acceptable abbreviations. Visit TJC's website at *www.jointcommission.org* and the Institute for Safe Medication Practices at *www.ismp.org* for current detailed safety information.

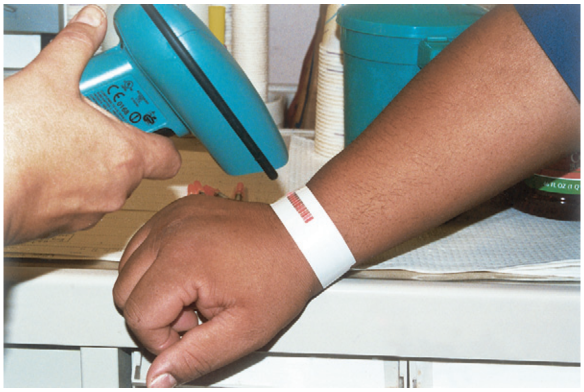

FIGURE 12–3 Bar code reader used to scan the patient's wristband. (From Kee JL, Marshall SM: *Clinical calculations: with applications to general and specialty areas,* ed. 7, St. Louis, 2013, Elsevier.)

TABLE 12-2 "DO NOT USE" ABBREVIATIONS

In 2005, The Joint Commission issued a new list of abbreviations that should not be used, but instead should be written out to avoid misinterpretation. Below is the list of "Do Not Use" abbreviations followed by a list of abbreviations that could possibly be included in future "Do Not Use" lists.

Abbreviation	Preferred
q.d., Q.D.	Write "daily" or "every day."
q.o.d., Q.O.D.	Write "every other day."
U	Write "unit."
IU	Write "International Unit."
MS, MSO$_4$	Write "morphine sulfate."
MgSO$_4$	Write "magnesium sulfate."
.5 mg	Use zero before a decimal point when the dose is less than a whole (write 0.X mg).
1.0 mg	Do not use a decimal point or zero after a whole number (write X mg).

The following abbreviations could **possibly be included** in future TJC "Do Not Use" lists.

Abbreviation	Preferred
c.c.	Use "mL" (milliliter).
Mg	Use "mcg" (microgram).
>	Write "greater than."
<	Write "less than."
Drug name abbreviations	Write out the full name of the drug.
Apothecary units	Use metric units instead.
@	Write "at."

Please visit *www.jointcommission.org* and *www.ismp.org* for more detailed safety information.

Another safety feature is the *black box,* or *boxed,* warning, the FDA's strongest labeling requirement, which warns health care providers of risks associated with certain drugs.

TABLE 12-3 ACCEPTABLE ABBREVIATIONS

TJC lists acceptable abbreviations in three categories: drug measurements and drug forms, routes of medication administration, and times of administration. Selected abbreviations are listed here. These are frequently used in drug therapy and must be known by the nurse.

Drug Measurements and Drug Forms

Abbreviation	*Meaning*
Cap	Capsule
Dr	Dram
Elix	Elixir
g, gm, G, GM	Gram
Gr	Grain
Gtt	Drops
Kg	Kilogram
l, L	Liter
m^2	Square meter
mcg, µg	Microgram
mEq	Milliequivalent
Mg	Milligram
mL, ml	Milliliter
m, min	Minim
Oz	Ounce
Pt	Pint
Qt	Quart
SR	Sustained release
ss., $\overline{ss}$	One half
Supp	Suppository
Susp	Suspension
T.O.	Telephone order
T, tbsp.	Tablespoon
t, tsp	Teaspoon
V.O.	Verbal order

Routes of Medication Administration

Abbreviation	*Meaning*
A.D., ad	Right ear
A.S., as	Left ear
A.U., au	Both ears
ID	Intradermal
IM	Intramuscular
IV	Intravenous
IVPB	Intravenous piggyback
KVO	Keep vein open
L	Left
NGT	Nasogastric tube
O.D., od	Right eye
O.S., os	Left eye
O.U., ou	Both eyes
PO, po, os	By mouth
®	Right
SC, subc, sc, SQ, subQ	Subcutaneous
SL, sl, subl	Sublingual
TKO	To keep open
Vag	Vaginal

Times of Administration

Abbreviation	*Meaning*
AC, ac	Before meals
ad lib	As desired
B.i.d., b.i.d.	Twice a day
$\bar{c}$	With
Hs	Hour of sleep
NPO	Nothing by mouth
PC, pc	After meals
PRN, p.r.n.	Whenever necessary, as needed
Q	Every
Qam	Every morning
Qh	Every hour
q2h	Every 2 hours
q4h	Every 4 hours
q6h	Every 6 hours
q8h	Every 8 hours
$\bar{s}$	Without
SOS	Once if necessary: if there is a need
Stat	Immediately
T.i.d., t.i.d.	Three times a day

Please visit *www.jointcommission.org* and *www.ismp.org* for more detailed safety information.

Joint Commission 2013 National Patient Safety Goals

TJC 2013 National Patient Safety Goals focus on problems in health care safety and how to solve them. National Patient Safety Goals program links for ambulatory health care, behavioral health care, critical access hospital, home care, hospitals, laboratory services, long-term care, long-term care (Medicare/Medicaid), and office-based surgery are found at *www.jointcommission.org/standards_information/npsgs.aspx*. As an example, the first three National Patient Safety Goals for hospitals have relevance for medication safety. They are as follows: Goal 1. Identify patients correctly; Goal 2. Improve staff communication; and Goal 3. Use medicines safely. The full text of the goals is available on TJC's website.

Medication Reconciliation

Medication reconciliation is an important component of the culture of safety. Medication discrepancies are not new in the literature. There are three transition points where many discrepancies occur: hospital admission, intrahospital transfer, and discharge. Medication reconciliation was created to provide medication continuity during care transitions, thereby promoting patient safety.

Medication reconciliation is the process of comparing a patient's medication orders to all of the medications that the patient has been taking. The purpose is to avoid errors (e.g., omissions, duplications, dosing errors, drug interactions). Reconciliation must be conducted at every transition of care when the patient is taking any medications. Transitions include changes in care setting, service, health care provider, or level of care.

The medication reconciliation process comprises five steps:

1. Develop a list of current medications.
2. Develop a list of medications to be prescribed.
3. Compare the medications on the two lists.
4. Make clinical decisions based on the comparison.
5. Communicate the new list to appropriate caregivers and to the patient.

Tips for Medication Reconciliation

- Conduct a thorough medication interview with patient and/or caregivers to obtain and verify current medication status and regimens.
- Teach patient/caregiver the key role of managing medication information at all transitions.
- Advise patient to give a list to his or her primary care provider; update own list when change in dose, deletion/addition of medication, including OTCs; and carry medication information at all times in case of an emergency.
- Enlist support of primary care physicians (all health care providers) and community pharmacists to encourage patients to carry and update their medication list at every encounter.
- The Agency for Healthcare Research and Quality (AHQR) has created a patient handout that can help patients play an active role in their own safety. Nurses can distribute the handout, found at *www.ahrq.gov/consumer/20tips.pdf*, during patient teaching.

Since 2005, TJC has required hospitals to perform medication reconciliation for all patients. The revised NSPG 03.06.01 requires facilities to "maintain and communicate accurate patient medication information." In addition, the Centers for Medicare and Medicaid Services Process of Care (Core) Measures require incorporating a reconciled medication list in the discharge instructions of all heart failure patients. In December 2011, the AHQR published *Medications at Transitions and Clinical Handoffs (MATCH) Toolkit for Medication Reconciliation;* it can be found at *www.ahrq.gov/qual/match/match1.htm*.

BOX 12-1 MEDICATIONS RECOMMENDED FOR DISPOSAL BY FLUSHING

MEDICINE	ACTIVE INGREDIENT
Abstral, tablets (sublingual)	Fentanyl
Actiq, oral transmucosal lozenge	Fentanyl citrate
Avinza, capsules (extended release)	Morphine sulfate
Daytrana, transdermal patch system	Methylphenidate
Demerol, tablets	Meperidine hydrochloride
Demerol, oral solution	Meperidine hydrochloride
Diastat/Diastat AcuDial, rectal gel	Diazepam
Dilaudid, tablets	Hydromorphone hydrochloride
Dilaudid, oral liquid	Hydromorphone hydrochloride
Dolophine hydrochloride, tablets	Methadone hydrochloride
Duragesic, patch (extended release)	Fentanyl
Embeda, capsules (extended release)	Morphine sulfate; naltrexone hydrochloride
Exalgo, tablets (extended release)	Hydromorphone hydrochloride
Fentora, tablets (buccal)	Fentanyl citrate
Kadian, capsules (extended release)	Morphine sulfate
Methadone hydrochloride, oral solution	Methadone hydrochloride
Methadose, tablets	Methadone hydrochloride
Morphine sulfate, tablets (immediate release)	Morphine sulfate
Morphine sulfate, oral solution	Morphine sulfate
MS Contin, tablets (extended release)	Morphine sulfate
Nucynta ER, tablets (extended release)	Tapentadol
Onsolis, soluble film (buccal)	Fentanyl citrate
Opana, tablets (immediate release)	Oxymorphone hydrochloride
Opana ER, tablets (extended release)	Oxymorphone hydrochloride
Oramorph SR, tablets (sustained release)	Morphine sulfate
Oxecta, tablets (immediate release)	Oxycodone hydrochloride
Oxycodone hydrochloride, capsules	Oxycodone hydrochloride
Oxycodone hydrochloride, oral solution	Oxycodone hydrochloride
Oxycontin, tablets (extended release)	Oxycodone hydrochloride
Percocet, tablets	Acetaminophen; oxycodone hydrochloride
Percodan, tablets	Aspirin; oxycodone hydrochloride
Xyrem, oral solution	Sodium oxybate

Disposal of Medications

The FDA collaborated with the White House Office of National Drug Control Policy (ONDCP) and in 2009 issued guidelines for appropriate disposal of prescription drugs. General guidelines include the following: Follow specific information on the drug label or drug insert. Unless specifically instructed, do not flush medications down the toilet, where they will pollute the environment and may be a danger to humans and animals. (Exceptions to this rule are listed in Box 12-1.) It is recommended that you remove the drug from its original container and dispose of it in a sealed bag with an undesirable substance such as used cat litter or used coffee grounds. This method is intended to make medications less attractive to people and animals. As needed, patients may take advantage of local community "drug take-back" programs that provide an opportunity for consumers to dispose of unwanted, unneeded, and/or expired medications in a safe manner. Some pharmacies will also take unused medications; this varies by state.

Before disposing of medication containers, all identifying information should be removed or obscured. Nurses and patients can consult a pharmacist with questions related to medication disposal.

Sharps Safety

The Occupational Safety and Health Administration (OSHA) Needlestick Safety and Prevention Act of 2000 resulted from the American Nurses Association's (ANA) campaign, *Safe*

Needles Save Lives. The Needlestick Safety and Prevention Act requires that employers do the following:

- Identify, evaluate, and implement safer medical devices.
- Maintain a sharps injury log.
- Involve health care workers in deciding which devices are used.
- Implement engineering controls for sharps disposal containers, self-sheathing needles, and safer medical devices like sharps with engineered injury protection and needleless systems. These engineering controls must be used to eliminate or lessen employee exposure to blood borne pathogens.
- Train employees in the proper usage of the engineering and work practice controls to help keep them safe.

Employers must ensure that no preventable sharps injuries occur. The Consensus Statement and Call to Action (2012), a collaboration of the ANA, the International Healthcare Worker Safety Center at the University of Virginia, and many health care colleagues, focuses on five areas: (1) improving sharps safety in surgical settings; (2) understanding and reducing exposure risks in nonhospital settings (e.g., offices, clinics, and home settings); (3) involving front-line workers in the selection of safety devices; (4) addressing gaps in available safety devices and encouraging innovative designs and technology; and (5) enhancing worker education and training.

SAFETY RISKS FOR MEDICATION ADMINISTRATION

It is estimated that for every 100 medication administrations, there are 5 medication errors. Several reports indicate that the majority of medication errors occur when administering the drug (41%), followed by documenting (21%), dispensing (17%), prescribing (11%), monitoring (1%), and other (9%).

Examples of risks to safety include the following:

- *Pill splitting*. In an effort to counteract steeply rising drug costs, some patients are cutting their pills in half. In the Half Tablet Program, with physician approval, patient costs are cut in half. However, splits can be dangerous. A minor dose change from uneven splitting can have a major effect on the patient. Patient attributes such as diminished vision, cognitive problems, and hand coordination problems can all contribute to the risk.
- *Buying drugs over the Internet*. This may be easy, but the buyer must be sure it is safe. Some websites are not state licensed or affiliated with pharmacies. They may not protect personal information; may not label, store, or ship medications correctly; and may sell expired medications. The FDA reports that consumers do not always get what they order and may not have someone available to verify if the drug is correct. Some sites may also sell counterfeit drugs (see the following paragraph). Patients should look for websites that require a prescription from a health care provider, have a licensed pharmacist to answer questions and a contact person if problems arise, are located in the United States, and are licensed by the state board of pharmacy.

Counterfeit Drugs

Counterfeit drugs look like the desired drug but may have no active ingredient, the wrong active ingredient, or the wrong amount of active ingredient. Improper packaging or contamination can also be problems. Counterfeit drugs may look remarkably like the real thing! To report suspect counterfeit products, call the FDA Office of Counterfeit Issues at 1-800-551-3989 or email *DrugSupplyChainIntegrity@fda.hhs.gov*.

To reduce the risk of exposure to counterfeit drugs, patients should do the following:

1. Purchase drugs only from licensed pharmacies. Refer to the National Association of Boards of Pharmacy (NABP) at *www.nabp.net* for information. The NABP reviews Internet pharmacies; after review, the NABP grants the Verified Internet Pharmacy Practice Sites (VIPPS) Accreditation Program seal. Visit *www.nabp.net/programs/accreditation/vipps/*.
2. Check the color, texture, shape, and taste (if applicable) of the drug when refilling a prescription. Patients should check with the pharmacist if they notice any changes.
3. Follow legislation in process to promote safe handling of drugs after they leave the authorized wholesaler by introducing "pedigree" requirements at federal and state levels.

Dosage Forms: To Crush or Not to Crush

Some medications can be crushed; consult with the health care provider or pharmacist. Do not crush any medication that has the suffix ER, SR, XR, SA, CR, MR, or XL; these are extended-release or sustained-release drugs, and crushing will change the location and speed of absorption. For a current complete listing of drugs that should not be crushed, see *www.ismp.org/Tools/Donotcrush.pdf*.

HIGH-ALERT MEDICATIONS

When high-alert drugs are involved in medication errors, the consequences to patients are more serious. Classes/categories of high-alert medications include IV adrenergic agents, IV adrenergic antagonists, IV antiarrhythmics; IV inotropic agents, IV moderate sedation agents, anesthetic agents, antithrombotic agents, cardioplegic solutions, chemotherapeutic agents, dextrose (hypertonic >20%), dialysis solutions, epidural or intrathecal agents, hypoglycemics, liposomal forms of drugs, moderate sedation agents, narcotics/opiates, neuromuscular blocking agents, IV radiocontrast agents, total parenteral nutrition solutions, sterile water for injection, inhalation and irrigation in containers of >100 mL, and sodium chloride for injection (hypertonic, >0.9% concentration). See *www.ismp.org/Tools/highalertmedications.pdf* for a complete list of classes/categories and specific medications. The ISMP recommends the following strategies to optimize safety when dealing with high-alert drugs: standardizing the ordering, storage, preparation, and administration of these products; improving access to information about these drugs; limiting access to high-alert medications; using auxiliary labels and automated alerts; and employing redundancies such as automated or independent double-checks when necessary.

LOOK-ALIKE AND SOUND-ALIKE DRUG NAMES

Nurses should be aware that certain drug names sound alike and are spelled similarly. Examples of drugs involved in medication errors and recognized as confused drug names include amaryl with reminyl; avinza with evista; cisplatin with carboplatin; Depakote with Depakote ER; ephedrine with epinephrine; and humalog mix 75/25 with Humulin 70/30. The FDA, ISMP, and TJC advocate the use of "tall man" letters as a safety strategy to reduce confusion between similar-sounding drugs. For example, rispiridone (Risperdal) is written as rispiriDONE, and ropinirole (Requip) is written as ropiniROLE to call attention to differences in spelling. Tall man letters should be used for computer listing and storage labeling.

OTHER FACTORS IN PREVENTION OF MEDICATION ERRORS

Creating a distraction- and interruption-free environment is critical to safe administration of medications. Effective strategies include creating a taped area on the floor surrounding the unit dose machine and hanging a sign stating, "Medication preparation/administration in progress. Please do not disturb"; hanging a card stating "Please do not interrupt during medication administration" on every computerized cart; designating a "quiet zone" for medication preparation; and wearing a vestlike garment that reads "Thank you for not interrupting" during medication preparation and administration.

Overall, the nurse's role is best achieved by the application of the nursing process. The nursing process related to medication safety follows.

Nursing Process
Patient-Centered Collaborative Care

Medication Safety

Assessment

- Assess vital signs and other patient parameters as appropriate. Report abnormal findings.
- Assess patient including patient history and ability to swallow (for PO medications).
- Assess medication order for completeness and with recommended parameters. Know purpose and expected effect of medication and interactions with other medications, including OTC and herbal preparations.
- Assess medication storage area (e.g., Does refrigerator storage meet requirements for medication storage?).

Planning

- Patient safety will be maintained/protected related to medication administration and use.

Nursing Interventions

- Calculate dose correctly.
- Use relevant resources appropriately.
- Avoid contamination of own skin or inhalation of substances to minimize exposure.
- Wash hands.
- Administer only medications you prepared.
- Determine patient's preferred language for communication, and mobilize resources to provide communication in this language.
- Identify patient by appropriate means (scanned name band, verbal confirmation).
- Remain with patient until medication has been taken.
- Administer medications according to the five-plus-five rights: right patient, right drug, right dose, right time, right route; plus right assessment, right documentation, right evaluation, right to education, right to refuse.
- Monitor subjective responses, physiologic alterations, and laboratory test results to identify therapeutic effects and adverse effects.
- Discard needles and syringes in appropriate container; be alert to sharps safety.
- Use aseptic/sterile technique appropriate for route of administration.
- Thoroughly document administration of medication(s) in the designated format in a timely manner.
- Document patient refusal to take medication, and notify health care provider.
- Follow up on effects of medication on patient.

Patient Teaching

- Counsel patient and family on anticipated effects of medications.
- Counsel patient on side effects and adverse reactions and what to report promptly to health care provider.
- Advise patient what foods to eat and/or avoid.
- Advise patient on taking medications before, with, or after meals, as appropriate, to promote optimal absorption.

Evaluation

- Evaluate patient's understanding of expected results from medication and what to report to health care provider.
- Evaluate effectiveness of medications administered to treat condition for which they were prescribed.

RESOURCES FOR PREVENTING ERRORS IN MEDICATION ADMINISTRATION

Several resources address medication errors and their prevention: (1) Pathways for Medication Safety was developed through the collaborative efforts of the American Hospital Association, the Health Research and Educational Trust, and the ISMP, with support from the Commonwealth Fund. Pathways for Medication Safety is a set of tools designed to assist hospitals through a system-based approach to reduce medication errors. (2) An FDA database of medication errors and "near misses" assists all health care personnel to identify, implement, and evaluate strategies to prevent medication errors. It is strongly suggested that health care workers report errors or near misses to the FDA. Reports are confidential. (3) The National Coordinating Council for Medication Error Reporting and Prevention (NCCMERP) specializes in medication errors from an interdisciplinary perspective. (4) The nurse must consult drug references (e.g., *United States Pharmacopeia, National Formulary,* and *American Hospital Formulary* drug reference handbook); human resources (e.g., pharmacists); and technology resources (Micromedex, Palm Pilot Epocrates) when unsure about the expected therapeutic effect, contraindications, dosage, potential side effects, or adverse reactions and interactions of a medication. (5) FDA MedWatch: Subscribe at *fda@service.govdelivery.com* for notifications on drug recalls, counterfeit products, and safety alerts.

PREGNANCY CATEGORIES

The FDA has developed a classification system related to the effects of drugs on the fetus. Table 12-4 lists the FDA's pregnancy categories and describes each category's effect on the fetus. Note: Prescription drug labeling revisions for health care providers are expected from the FDA. The purpose of the changes is to optimize informed decision making for pregnant patients and for patients of childbearing age who may wish to become pregnant. Both the pregnancy and lactation subsections will have three principal components: risk summary, clinical considerations, and a data section. The current pregnancy categories will be eliminated when the revisions have been completed.

FACTORS THAT MODIFY DRUG RESPONSE

Effects on the patient from drugs are complex owing to alterations in physiology. Nurses must complete thorough assessments of patients to accurately evaluate drug effects. Examples of factors that modify drug responses specifically related to safety include **absorption, distribution,** metabolism, excretion, **toxicity, pharmacogenetics,** pre-existing disease state, and drug-drug interaction. See discussions of factors that modify drug response in Chapters 1, 3, 4, 6, 7, and 8.

GUIDELINES FOR MEDICATION ADMINISTRATION

General guidelines for medication administration are listed in Boxes 12-2 and 12-3. Nurses should follow these guidelines to enhance safety when administering medications. Application of the nursing process to medication administration is presented in Chapter 13.

TABLE 12-4 FDA PREGNANCY CATEGORIES

PREGNANCY CATEGORY	DESCRIPTION
A	No risk to fetus. Studies have not shown evidence of fetal harm.
B	No risk in animal studies, and well-controlled studies in pregnant women are not available. It is assumed there is little to no risk in pregnant women.
C	Animal studies indicate a risk to the fetus. Controlled studies on pregnant women are not available. Risk versus benefit of the drug must be determined.
D	A risk to the human fetus has been proved. Risk versus benefit of the drug must be determined. It could be used in life-threatening conditions.
X	A risk to the human fetus has been proved. Risk outweighs the benefit, and drug should be avoided during pregnancy.

BOX 12-2 GUIDELINES FOR CORRECT ADMINISTRATION OF MEDICATIONS

Preparation

1. Wash hands before preparing medications.
2. Check for drug allergies; check the assessment history and Kardex.
3. Check medication order with health care provider's orders, Kardex, medicine sheet, or medicine card.
4. Check label on drug container three times.
5. Check expiration date on drug label, card, and Kardex; use only if date is current.
6. Recheck drug calculation of drug dose with another nurse as needed or by agency policy.
7. Verify doses of drugs that are potentially toxic with another nurse or pharmacist.
8. Pour tablet or capsule into the cap of the drug container. With unit dose, open packet at bedside after verifying patient identification.
9. Pour liquid at eye level. The meniscus (the lower curve of the liquid) should be at the line of desired dose (see Figure 13-2).

BOX 12-2 GUIDELINES FOR CORRECT ADMINISTRATION OF MEDICATIONS—cont'd

10. Dilute drugs that irritate the gastric mucosa (e.g., potassium, aspirin), or give with meals.

Administration

11. Administer only drugs that you have prepared. Do not prepare medications to be administered by another person.
12. Identify the patient by ID band or ID photo.
13. Offer ice chips to numb the patient's taste buds when giving bad-tasting drugs.
14. When possible, give bad-tasting medications first, followed by pleasant-tasting liquids.
15. Assist the patient to an appropriate position, depending on the route of administration.
16. Provide only amounts and kinds of liquids allowed on the diet.
17. Stay with the patient until the medications are taken.
18. Administer no more than 2.5 to 3 mL of solution intramuscularly at one site. Infants receive no more than 1 mL of solution intramuscularly at one site and no more than 1 mL subcutaneously. Never recap needles (Universal Precautions).
19. When administering drugs scheduled at the same time to a group of patients, give drugs last to patients who need extra assistance.
20. Discard needles and syringes in appropriate containers.
21. Drug disposal is dependent on agency policy and state law. For example, discard drugs in the sink or toilet, not in the trash can. Controlled substances must be returned to the pharmacy. Some disposals need signatures of witnesses; refer to agency policy.
22. Discard unused solutions from ampules.
23. Appropriately store (some require refrigeration) unused stable solutions from open vials.
24. Write date and time opened and your initials on the label.
25. Keep narcotics in a double-locked drawer or closet. Medication carts must be locked at all times when a nurse is not in attendance.
26. Keys to the opioids drawer must be kept by the nurse and not stored in a drawer or closet.
27. Keep opioids in a safe place, out of reach of children and others in the home.
28. Avoid contamination of one's own skin or inhalation to minimize chances of allergy or sensitivity development.

Recording

29. Report drug error immediately to the patient's health care provider and to the nurse manager.
30. Complete an incident report.
31. Charting: record drug given, dose, time, route, and your initials.
32. Record drugs promptly after given, especially STAT doses.
33. Record effectiveness and results of medication administered, especially PRN medications.
34. Report to the patient's health care provider and record drugs that were refused with the reason for refusal.
35. Record amount of fluid taken with medications on input and output chart.

ID, Identification; *PRN,* as needed; *STAT,* immediately.

BOX 12-3 BEHAVIORS TO AVOID DURING MEDICATION ADMINISTRATION

Do not be distracted when preparing medications.
Do not give drugs poured by others.
Do not pour drugs from containers with labels that are difficult to read or whose labels are partially removed or have fallen off.
Do not transfer drugs from their original, labeled container to another for storage.
Do not pour drugs into the hand.
Do not give medications for which the expiration date has passed.
Do not guess about drugs and drug doses. Ask when in doubt.
Do not use drugs that have sediment, are discolored, or are cloudy (and should not be).
Do not leave medications by the bedside or with visitors.
Do not leave prepared medications out of sight.
Do not give drugs if the patient says he or she has allergies to the drug or drug category.
Do not call the patient's name as the sole means of identification.
Do not give drug if patient states drug is different from drug he or she has been receiving. Check order.
Do not recap needles. Use Universal Precautions.
Do not mix drugs with large amount of food or beverages.

NCLEX STUDY QUESTIONS

1. A patient asks about disposal of medications. What are the nurse's best responses?
(Select all that apply.)
   - a. "Mix medications with coffee grounds before disposal."
   - b. "Pour medications down the sink."
   - c. "Remove identifying information on the original container."
   - d. "Pulverize all tablets before disposal."
   - e. "Dilute the medication with bleach before disposal."
2. The patient is taking duastride (Avodart). Which patient statement indicates the need for more education about the drug?
   - a. "I'm glad I can take the medication with or without food."
   - b. "It is good that no lab tests and monitoring are required."
   - c. "This drug is expensive; I'm glad I have prescription coverage."
   - d. "I prefer to chew the drug before swallowing it."
3. The nurse educator on the unit receives a list of high-alert drugs. Which strategy is recommended to decrease the risk of errors with these medications? (Select all that apply.)
   - a. Store medications alphabetically on their usual shelf.
   - b. Limit access to these drugs.
   - c. Use special labels for these drugs.
   - d. Provide increased information to staff.
   - e. Standardize the ordering and preparation of these drugs.
4. The nurse is aware that, according to TJC, which abbreviation is on the "Do Not Use" list for ordering or documenting medications?
   - a. QD
   - b. h.s.
   - c. T.I.W.
   - d. b.i.d.
5. A patient refuses to take his prescribed medications. Which is the nurse's best response to this patient?
   - a. Explain the benefits and side effects of the drug.
   - b. Leave the medication at the patient's bedside to be taken later.
   - c. Persuade the patient to take the medication.
   - d. Explain the risks of not taking the medication.
6. What information is essential for the nurse to know related to right documentation? (Select all that apply.)
   - a. Necessity to document all medications given at the end of shift
   - b. Correct site of injectable medication
   - c. Patient response to antiemetic
   - d. Drug name, dose, route
   - e. Date and time of dose and necessity for RN initial/signature
7. The nurse prepares to administer medications. Which are complete drug orders? (Select all that apply.)
   - a. Aspirin 81 mg, PO, daily
   - b. Multivitamin 1 daily
   - c. Vitamin D, 2000 units, PO
   - d. Ciprofloxacin HCl (Cipro) 500 mg PO q 12h × 7d
   - e. Promethazine 50 mg IV q3-6h PRN for nausea

Answers: 1, a, c; 2, d; 3, b, c, d, e; 4, a; 5, d; 6, b, c, d, e; 7, a, d, e.

OBJECTIVES

- Differentiate routes of administration.
- Compare and contrast the various sites for parenteral therapy.
- Explain the equipment and technique used in parenteral therapy.
- Explain documenting medication administration.
- Analyze the nursing interventions related to administration of medications by various routes.
- Apply the nursing process to the administration of medication.

Administration of medications is a basic activity in nursing practice. As a result of the transition from hospitals and institutions to community-based services, an increasing number of nurses are practicing in a variety of settings. Nurses therefore must be knowledgeable about specific drugs and their administration, patient response, drug interactions, patient allergies, and related resources. Safety and prevention of medication errors are essential (see Chapter 12).

SELF-ADMINISTRATION OF MEDICATION

Self-administration of medication (SAM) is common in the home and in many community-based settings like the workplace. However, SAM is relatively new to patients and staff in institutional settings. In practical terms, SAM means that the nurse gives the patient the appropriate medications and instructions that are kept at the bedside and then go home with the patient on discharge. Patients are responsible for taking their medication according to the instructions. Patients play a key role in and exercise control associated with taking selected medications. SAM allows patients to manage their medications during the hospital admission and prepares them to manage their medications at home for optimal benefits. Refer to Chapters 53 and 54 for a description of SAM for maternity patients and Chapter 12 for the "five-plus-five rights," the "do's and don'ts" of medication administration, factors that alter drug responses, high-alert medications, and pregnancy categories.

FORMS AND ROUTES FOR DRUG ADMINISTRATION

A variety of forms and routes are used for the administration of medications, including **sublingual, buccal,** oral (tablets, capsules, liquids, suspensions, elixirs), transdermal, topical, instillation (drops and sprays), **inhalation,** nasogastric and gastrostomy tubes, **suppositories,** and **parenteral** (Figure 13-1).

Tablets and Capsules

- Tablets and capsules are the most common drug forms; they are convenient and less expensive and do not require additional supplies for administration.
- Oral medications are not given to patients who are vomiting, lack a gag reflex, or who are comatose. Patients who gag may need a brief rest before proceeding with further intake of medications.
- Do not mix medication with a large amount of food or beverage or with contraindicated food. Patients may not be able to eat all of the food and will not get a full dose of medication. Do not mix medication in infant formula.
- Enteric-coated and timed-release capsules must be swallowed whole to maintain a therapeutic drug level. If crushed, the initial excessive drug release poses a risk of toxicity. Because the drug is absorbed prematurely, the drug drops to a subtherapeutic level later in the cycle. To maintain a therapeutic drug level (not toxic and not subtherapeutic), the drug must be swallowed whole so it is released gradually. These medications should never be cut in half or crushed for administration. Follow agency policy for resources available for changing or altering such drugs if patients are unable to swallow them. At times, these medications can be given in liquid or IV form or in a non–extended-release form that may be given in more frequent doses—for example, Roprol XL (metaprolol succinate), which is long-acting, may be changed to Lopressor (metaprolol tartate), which is immediate-release and can be given more frequently.
- Be aware of medications without "extended-release" in the name that should never be cut in half or crushed (e.g., Mucinex tablets, which can be changed to liquid guaifenesin if needed).
- Administer irritating drugs with food to decrease GI discomfort.
- Administer drugs on an empty stomach if food interferes with medication absorption.
- Drugs given sublingually (placed under the tongue) or buccally (placed between the cheek and gum) remain in place until fully absorbed. No food or fluids should be taken while the medication is in place.
- Encourage the use of child-resistant caps. However, if patients have difficulty opening child-resistant caps, they might leave the caps off or not completely tightened, which is a safety hazard. Non–child-resistant caps are available for these patients on request.

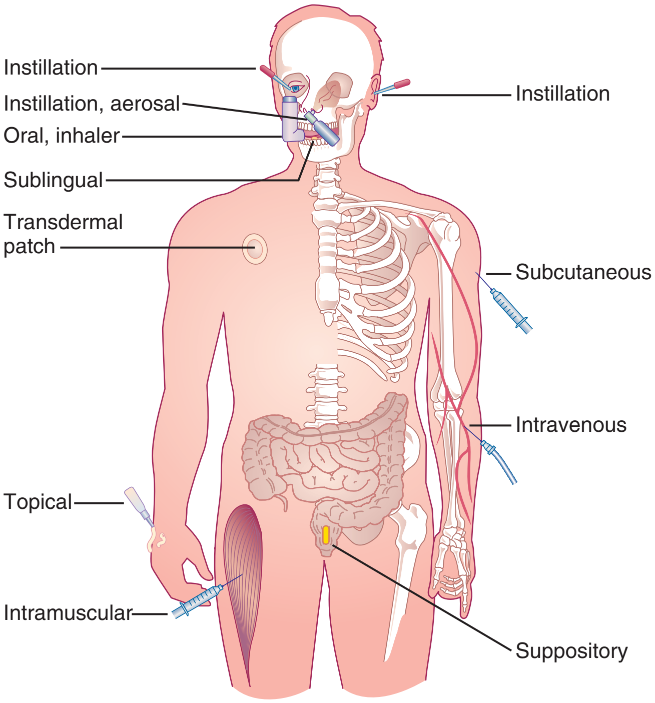

FIGURE 13–1 Some routes for medication administration.

Liquids

- Forms of liquid medication include elixirs, emulsions, and suspensions. Elixirs are sweetened hydroalcoholic liquids used in preparation of oral liquid medications. Emulsions are a mixture of two liquids that are not mutually soluble. Suspensions are liquids in which particles are mixed but not dissolved.
- Read the labels to determine whether dilution or shaking is required. As a general rule, suspensions and emulsions need to be shaken before administration; elixirs do not.
- The **meniscus** is the slightly concave curved line of a dose of liquid. The bottom of the meniscus should be used to measure the desired dose of medication (Figure 13-2).
- Many liquids require refrigeration once reconstituted.

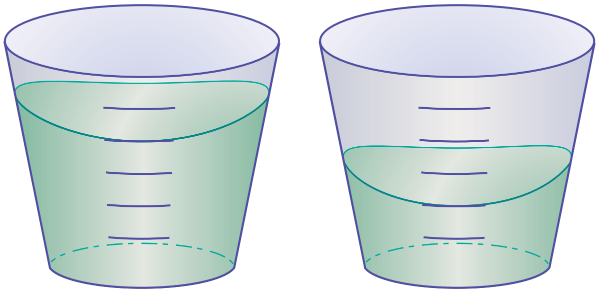

FIGURE 13–2 To read the meniscus, locate the lowest fluid mark.

Transdermal

- **Transdermal** medication is stored in a patch placed on the skin and absorbed through skin, having a systemic effect. Widespread use of such patches began in the 1980s. Patches for neoplastic drugs, drugs to treat allergic reactions, and insulin are in production or being developed. Transdermal drugs provide more consistent blood levels than oral and injection forms and avoid GI absorption problems associated with oral products. Transdermal patches should be rotated to different sites and not reapplied over the exact same area when changed. Additionally, the area should be thoroughly cleansed before administration of a new transdermal patch. This practice will prevent errors in overdosing the patient.
- Wash hands and wear gloves to administer medicated patches to prevent transfer of medication. Nurses should educate patients to wash hands after applying a patch to avoid transferring medicine to another part of body or to someone else.
- A common question is whether or not to cut the patches in half. A nurse might suggest using patches with a lower dosage rather than cutting patches and guessing the dose the patient will receive. There are two patch designs: (1) If the drug is embedded in a matrix patch and diffuses into the skin (e.g., Climara, Vivelle, Nicotrol, Testoderm), the drug is spread over the entire surface of the patch, which probably may be cut. Patients must be alert for underdosing or overdosing. (2) If the drug is pooled in a reservoir patch and is released via a semipermeable membrane (e.g., Catapres-TTS, Duragesic, Estraderm, Transderm-Nitro, Androderm), the patch should not be cut because too much drug may be released. Advise patients to secure the patch with tape, being careful not to apply it too tightly, which could alter the drug delivery.

Topical

- **Topical** medications are most frequently applied to the skin. They can be applied to the skin in several ways, such as with a glove, tongue blade, or cotton-tipped applicator. Nurses should never apply a topical medication without first protecting their own skin with gloves.
- Use appropriate technique to remove the medication from the container, and apply it to clean, dry skin, when possible. Do not contaminate the medication in a container; instead use gloves or an applicator.
- Gloves and applicators that come in contact with a patient should not be reinserted into the container. Estimate the amount needed and remove it from the container, or use a fresh sterile applicator each time the container is entered.

BOX 13-1 ADMINISTRATION OF EYEDROPS

1. Wash hands and wear gloves.
2. Instruct patient to lie down or sit down and look at ceiling.
3. Remove any discharge by gently wiping out from inner canthus. Use a separate cloth for each eye.
4. Gently draw skin down below affected eye to expose conjunctival sac.
5. Notify patient immediately before drops are administered so patient is prepared to avoid blinking when drops hit the conjunctiva.
6. Administer prescribed number of drops into center of sac. Medication placed directly on the cornea can cause discomfort or damage. Avoid touching eyelids or eyelashes with dropper. Self-administration of drops is enhanced with use of a Drop-eze, a cuplike device that holds the eyelids open.
   a. Gently press on lacrimal duct with a sterile cotton ball or tissue for 1 to 2 minutes after instillation to prevent systemic absorption through the lacrimal canal.
   b. Instruct patient to keep eyes closed for 1 to 2 minutes after application to promote absorption.

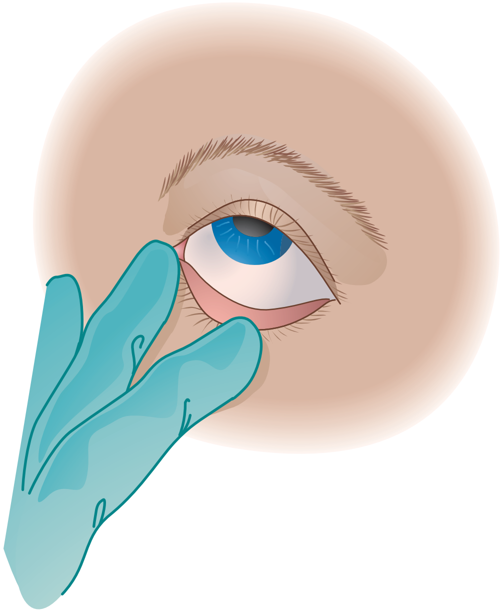

FIGURE 13–3 To administer eyedrops, gently pull down the skin below the eye to expose the conjunctival sac. Apply drops to the middle third of the sac, and apply gentle pressure over the lacrimal duct after administration.

Instillations

Instillations are liquid medications usually administered as drops, ointment, or sprays in the following forms:

- Eyedrops (Box 13-1 and Figure 13-3)
- Eye ointment (Box 13-2 and Figure 13-4)

BOX 13-2 ADMINISTRATION OF EYE OINTMENT

1. Wash hands and wear gloves.
2. Instruct patient to lie down or sit down and look at ceiling.
3. Remove any discharge by gently wiping out from inner canthus. Use a separate cloth for each eye.
4. Gently draw skin down below affected eye to expose conjunctival sac.
5. Prepare patient by explaining that ointment will be placed in the eye so patient can help by not blinking.
6. Squeeze a strip of ointment (about ¼ inch unless stated otherwise) onto conjunctival sac. Medication placed directly on the cornea can cause discomfort or damage. Avoid touching eyelids or eyelashes with tip of applicator.
7. Instruct patient to close eyes for 2 to 3 minutes.
8. Instruct patient to expect blurred vision for a short time. Apply at bedtime if possible.

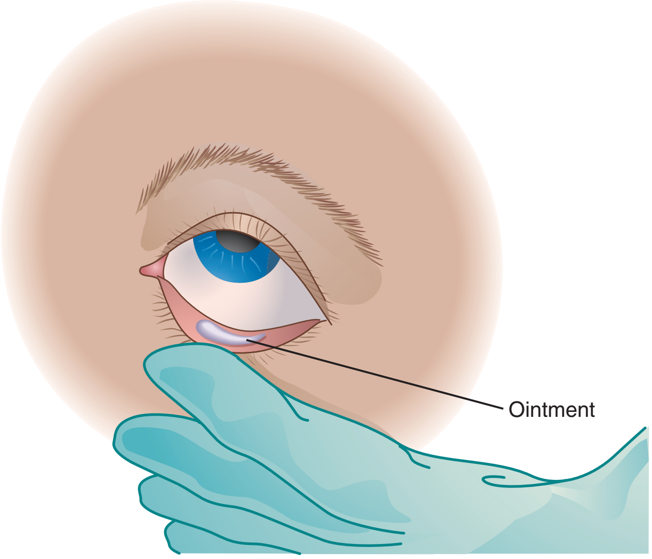

FIGURE 13–4 To administer eye ointment, squeeze a ¼-inch–wide strip of ointment onto the conjunctival sac.

- Eardrops (Box 13-3 and Figure 13-5)
- Nose drops and sprays (Box 13-4 and Figures 13-6 and 13-7)

Inhalations

- **Metered-dose inhalers (MDIs)** are handheld devices that deliver medication to the lower respiratory tract (Box 13-5). Some MDIs have a counter to indicate the number of inhalations used. For those that do not, the most accurate way to determine this number is for the patient to count and record (e.g., on the box or a calendar) the number of inhalations used; however, this is often not practical. Inhalation counters are now on some inhalation products and are a most welcome addition. Every effort should be made to have the patient know how much medication is in the canister and to anticipate/obtain refills in a timely manner.

BOX 13-3 ADMINISTRATION OF EARDROPS

1. Wash hands.
2. Have medication at room temperature.
3. Instruct patient to sit up with head tilted slightly toward unaffected side. This position straightens the external ear canal for better visualization. Maintain this position for 2 to 3 minutes to facilitate drops reaching the affected area (see Figure 13-5).
4. Pull down and back on the auricle for a child younger than 3 years of age. (For children 3 years of age and older, use the same procedure as for an adult.) For an adult, pull up and back on the auricle.
5. Instill prescribed number of drops. Take measures to avoid allowing drops to fall directly on tympanic membrane. Drops should be aimed at side of ear canal and allowed to run down into ear.
6. Do not contaminate dropper.

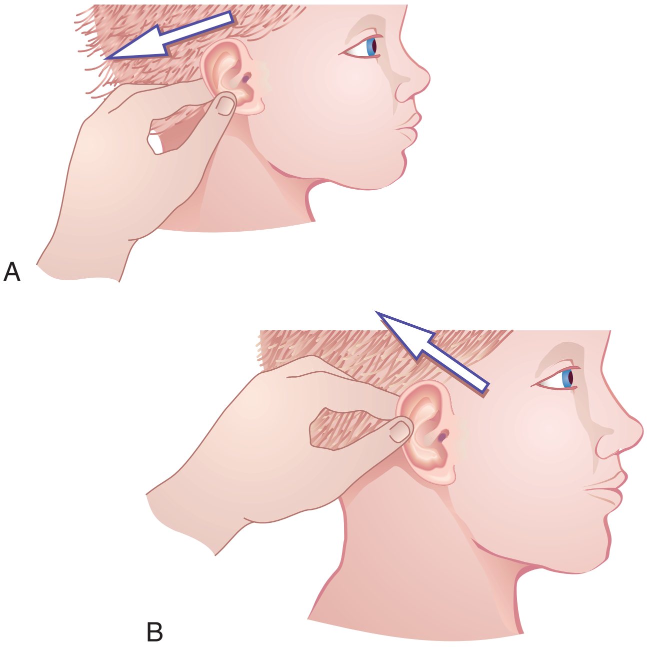

FIGURE 13–5 To administer eardrops, straighten the external ear canal by pulling down on the auricle in children younger than 3 years of age **(A)** or pulling back on the auricle in older children and adults **(B)**.

BOX 13-4 ADMINISTRATION OF NOSE DROPS AND SPRAYS

1. Wash hands and wear gloves.
2. Advise patient to blow nose.
3. Advise patient to tilt head back for drops to reach frontal sinus and tilt head to affected side to reach ethmoid sinus.
4. Administer prescribed number of drops or sprays without touching tip of medication applicator to nasal passages.
5. Some sprays have instructions to close one nostril, tilt head to closed side, and hold breath or breathe through the nose for 1 minute.
6. If patient is using a nasal spray to reach the sinuses, proper head position is with patient looking down at feet and spray tip aimed toward eye.
7. Advise patient to keep head tilted backward for 5 minutes after instillation of drops.

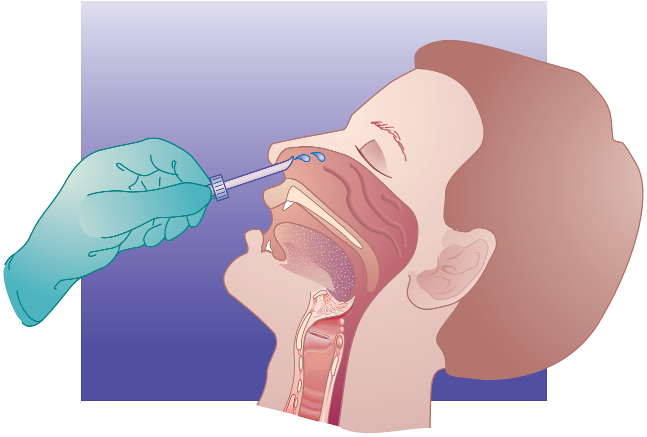

FIGURE 13–6 Administering nose drops.

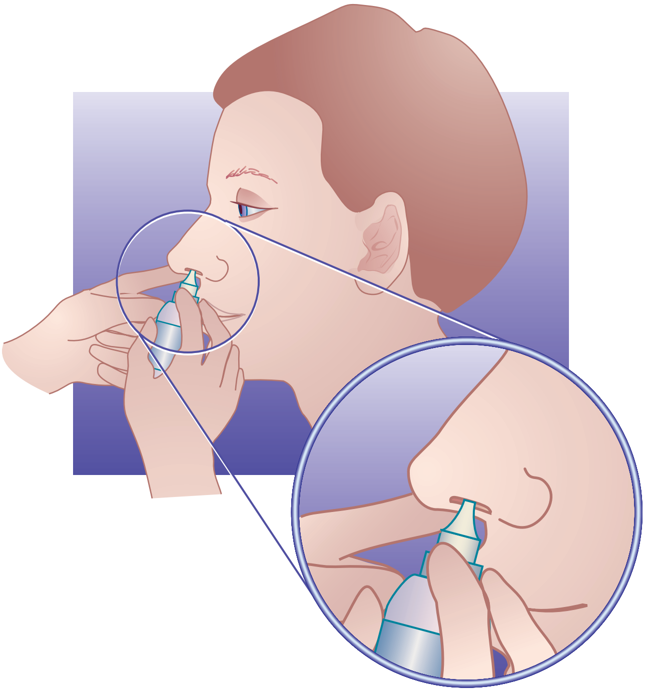

FIGURE 13–7 Administering nasal spray.

- Take special measures when handling the capsules used in some MDIs to prevent the transfer of medication (for example, with Spiriva, if the powder from the punctured capsule gets on the nurse's hands and transfers to the eyes, it will dilate the pupils).
- **Spacers** are devices used to enhance the delivery of medications from the MDI. Figure 13-8 illustrates the distribution of medication with and without a spacer. A nebulizer is a device that changes a liquid medication into a fine mist or aerosol that has the ability to reach the lower, smaller airways. Handheld nebulizers deliver a very-fine–sized particle spray of medication.
- When administering drugs via an MDI or nebulizer, the preferred patient position is the semi-Fowler's or high Fowler's position.

BOX 13-5 CORRECT USE OF METERED-DOSE INHALER

1. Discuss preferred techniques with health care provider.
2. Insert medication canister into plastic holder.
3. Shake inhaler well before using. Remove cap from mouthpiece.
4. Breathe out through mouth. Open mouth wide, and hold mouthpiece 1 to 2 inches from mouth. Do not put mouthpiece in mouth unless using a spacer.
5. Take slow, deep breath through mouth and, during inspiration, push top of medication canister once.
6. Autohalers do not require coordination of pushing down top of canister and taking deep breath. With autohaler in upright position, raise lever and shake. Inhale deeply through mouthpiece with steady, moderate force, which triggers the release of medicine, making a "click" sound and puffing out medicine. Continue to take deep breaths.
7. Hold breath for 10 seconds; exhale slowly through pursed lips.
8. Wait 1 to 2 minutes, and repeat procedure by first shaking canister in plastic holder with cap on, if a second dose is required.
9. "Test spray" before administering metered dose if inhaler has not been used recently or when it is first used.
10. Wait 5 minutes before using inhaler containing steroid, if a glucocorticoid inhalant is to be used with a bronchodilator.
11. Teach patient to monitor pulse rate.
12. Caution against overuse, because side effects and tolerance may result.
13. Teach patient to monitor amount of medication remaining in canister. Advise patient to ask health care provider or pharmacist to estimate when a new inhaler will be needed based on dosing schedule.
14. Teach patient to rinse mouth after using metered-dose inhaler. This is especially important when using a steroid drug. Rinsing mouth helps prevent irritation and secondary infection to oral mucosa.
15. Advise patient to avoid smoking.
16. Teach patient to do daily cleaning of equipment, including (1) wash hands; (2) take apart all washable parts of equipment and wash with warm water; (3) rinse; (4) place on clean towel, and cover with another clean towel to air-dry; and (5) store in clean plastic bag when completely dry. Recommendation: alternate two sets of washable equipment to make this process easier.

- Instruct the patient on the correct use and cleaning of MDIs or nebulizers.

Nasogastric and Gastrostomy Tubes

- Check for proper tube placement before administering medications. Replace any aspirated gastric fluid.
- Pour drug into syringe without plunger or bulb, release clamp, and allow medication to flow in properly, usually by gravity.
- Flush tubing with 50 mL of water, or the prescribed amount. (Refer to agency policy for exact amount.)
- Clamp tube and remove syringe.
- If the patient has a nasogastric tube to suction, clamp the tube for 30 minutes before placing the patient back on suction to allow medication to be absorbed.

Suppositories

Rectal Suppositories

- Medications administered as suppositories or enemas can be given rectally for local and systemic absorption. The

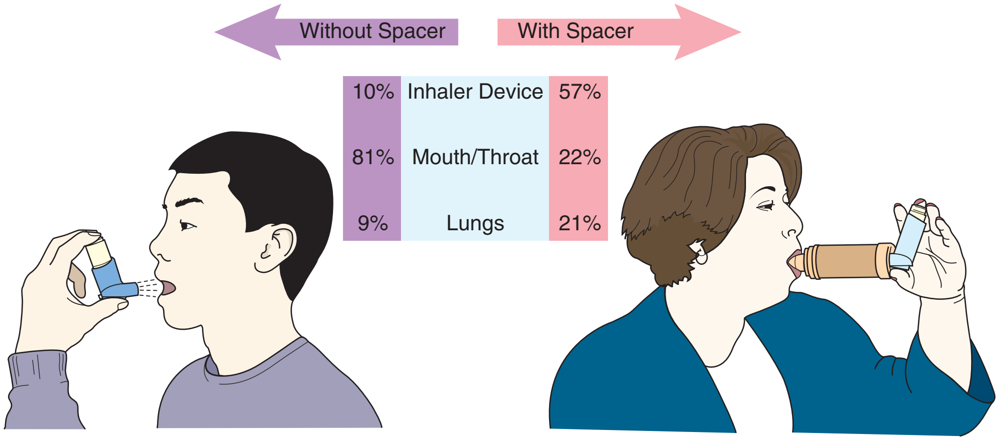

FIGURE 13–8 Distribution of medication with and without a spacer.

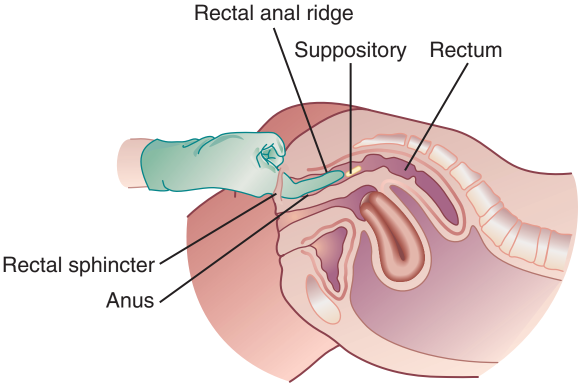

FIGURE 13–9 Inserting a rectal suppository.

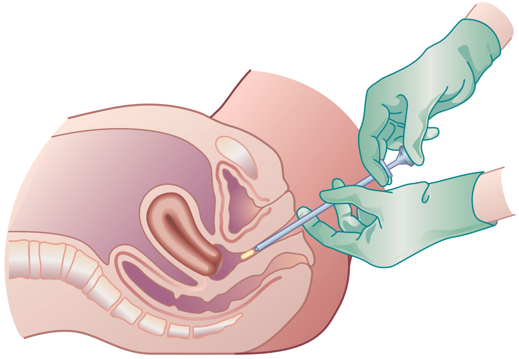

FIGURE 13–10 Inserting a vaginal suppository.

numerous small capillaries in the rectal area promote medication absorption.

- The foil around the suppository is removed, and the suppository may be lubricated before insertion. When medications such as antipyretics and bronchodilators are given, the patient must be reminded to retain the medication, not expel it.
- Suppositories tend to soften at room temperature and therefore must be refrigerated before use.
- Explain the procedure to the patient, and provide privacy.
- Use a glove for insertion.
- Instruct the patient to lie on the left side and breathe through the mouth to relax the anal sphincter.
- Apply a small amount of water-soluble lubricant to tip of unwrapped suppository, and gently insert suppository beyond the internal sphincter (Figure 13-9).
- Have patient lie on the side for 20 minutes after insertion.
- If indicated, teach patients how to self-administer suppositories, and observe a return demonstration for teaching effectiveness.

Vaginal Suppositories

Vaginal suppositories are similar to rectal suppositories. They are generally inserted into the vagina with an applicator supplied with the medication (Figure 13-10); gloves should be worn. The patient should be in the lithotomy position. Advise patient to remain lying for a period of time to allow medication absorption; times vary depending on medication. After insertion, provide the patient with a sanitary pad.

Parenteral

Safety is a special concern with parenteral medication (medication administered via injection to bypass the first-pass effect of the liver). Manufacturers have responded with safety features to help decrease or eliminate needlestick injuries and possible transfer of bloodborne diseases such as hepatitis and human immunodeficiency virus (HIV). (Figure 13-11 shows examples of safety needles.) Types of parenteral routes include **intradermal, subcutaneous, intramuscular, Z-track technique, intravenous,** and **intraosseous.** A description of each follows with special considerations noted for the pediatric patient.

Intradermal

Action

- Local effect
- Used for observation of an inflammatory (allergic) reaction to foreign proteins. Examples include tuberculin testing, testing for drug and other allergic sensitivities, and some immunotherapy for cancer.

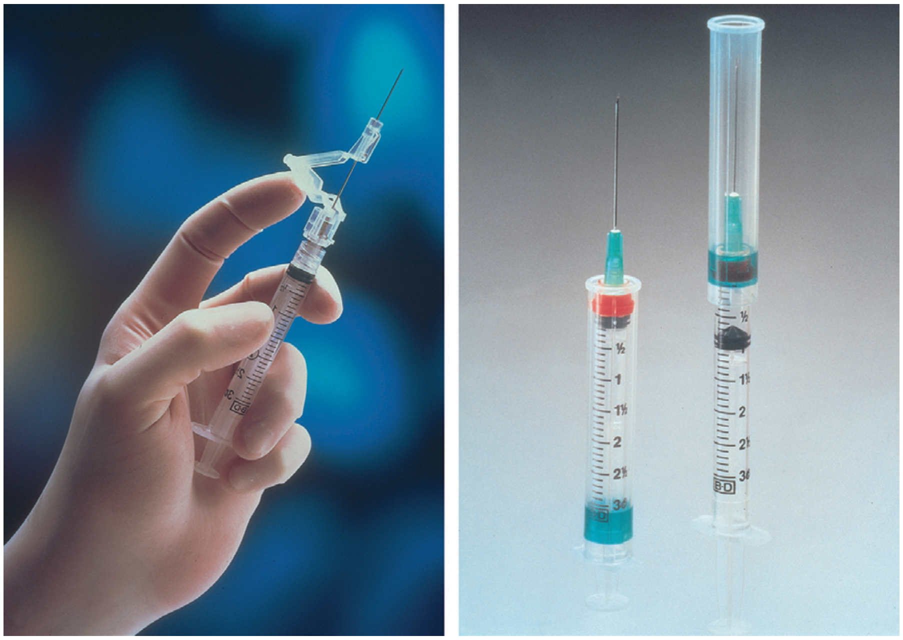

FIGURE 13–11 Safety needles. (Courtesy of Becton, Dickinson and Company, Franklin Lakes, New Jersey.)

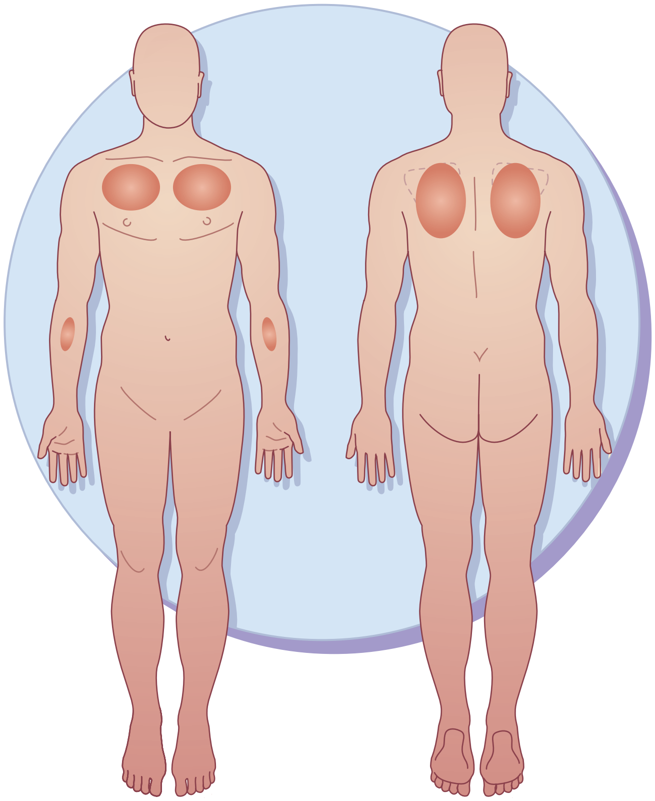

FIGURE 13–12 Common sites for intradermal injection.

Sites

- Locations are chosen so an inflammatory reaction can be observed. Preferred areas are lightly pigmented, thinly keratinized, and hairless, such as the ventral mid-forearm, clavicular area of the chest, or scapular area of the back (Figure 13-12).

Equipment

- Needle: 25- to 27-gauge; $\frac{3}{8}$ to $\frac{5}{8}$ inch long
- Syringe: 1 mL calibrated in 0.01-mL increments (usually 0.01 to 0.1 mL injected)

Technique

- Wash hands and wear gloves.
- Cleanse the area with a circular motion using aseptic technique.
- Hold the skin taut.
- Insert the needle, bevel up, at a 10- to 15-degree angle; the outline of the needle under the skin should be visible (Figure 13-13).
- Inject the medication slowly to form a wheal (blister or bleb). A small amount is injected so volume will not interfere with wheal formation or cause a systemic reaction. If the wheal does not appear, the needle is too deep; the medication may not be effective, and the injection will have to be given at another site.
- Remove the needle slowly; do not recap.
- Do not massage the area; instruct the patient not to do so.
- Mark the area with a pen, and ask the patient not to wash it off until read by a health care provider.
- Assess for allergic reaction in 24 to 72 hours; measure the diameter of local reaction. For tuberculin testing, measure only the indurated area; do not include the area of erythema in the measurement.

Subcutaneous

Action

- Systemic effect
- Sustained effect; absorbed mainly through capillaries; usually slower in onset than with IM route

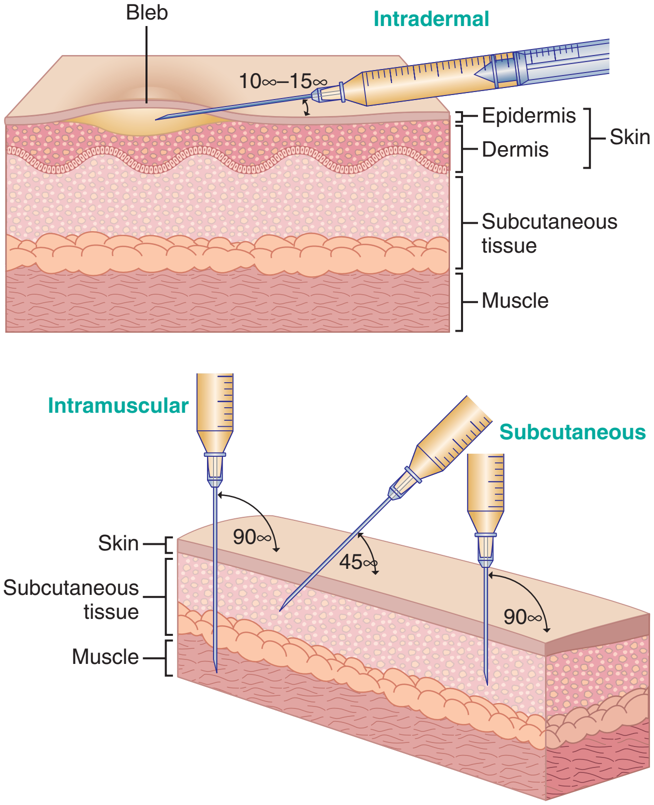

FIGURE 13–13 Needle-skin angle for intradermal, subcutaneous, and intramuscular injections.

Sites

- Locations for subQ injection are chosen for adequate fat-pad size (Figure 13-14). Sites should be rotated with subcutaneous injections, such as insulin and heparin, and documented on appropriate records to avoid overuse of an individual site.
- A larger amount of medication may have to be divided and administered at two sites, or else the medication route may be changed. Refer to agency policy for the maximum amount of medication to be administered via this route.

Equipment

- Needle: 25- to 27-gauge; ½ to ⅝ inch long
- Syringe: 1 to 3 mL (usually 0.5 to 1 mL injected)
- Insulin syringe measured in units for use with insulin only

Technique

- Wash hands and wear gloves.
- Cleanse the area with a circular motion using aseptic technique.
- Pinch the skin.
- Insert the needle at an angle appropriate to body size: 45 to 90 degrees (45 degrees for those with little subQ tissue) (see Figure 13-14).
- Release the skin.
- Do not aspirate.
- Inject the medication slowly.
- Remove the needle quickly; do not recap.
- Gently massage the area unless contraindicated.

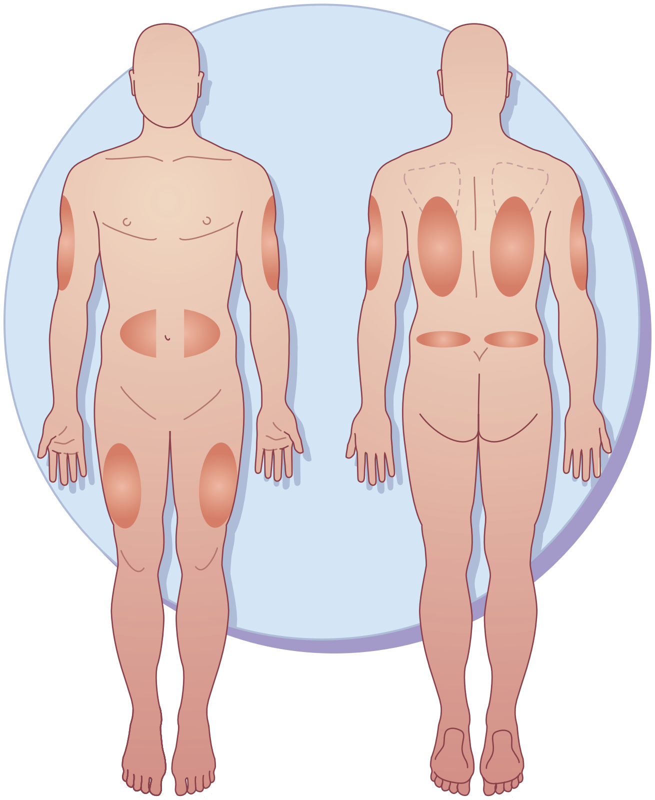

FIGURE 13–14 Common sites for subcutaneous injections.

- Apply gentle pressure to the injection site to prevent bleeding or oozing into the tissue and subsequent bruising and tissue damage, especially if the patient is on anticoagulant therapy.
- Apply bandage if needed.

Intramuscular

Action

- Systemic effect
- Usually more rapid effect of drug than with subQ route
- Used for solutions in oils and deep IM for irritating drugs

Sites. Locations are chosen for adequate muscle size and minimal major nerves and blood vessels in the area (see Figures 13-15 to 13-18). Other considerations include volume of drug administered, needle size, angle of injection, patient position, site location, and advantages and disadvantages of site. Underweight patients should be evaluated for sites with adequate muscle. The ventrogluteal is the preferred site for adults and toddlers with gluteal muscle development associated with firmly established walking.

Equipment

- Needle: 20- to 23-gauge; 18-gauge for blood products; 1 to 1½ inches long

Technique

- Wash hands and wear gloves.
- Same as for subQ injection, with two exceptions: Flatten the skin area using the thumb and index finger, and inject between them; insert the needle at a 90-degree angle into the muscle (see Figure 13-14).
- Syringe: 1 to 3 mL (usually 0.5 to 1.5 mL injected)

Preferred Intramuscular Injection Sites. Table 13-1 shows the four sites, patient position, advantages, and disadvantages of each injection site.

- *Ventrogluteal* (Figure 13-15). Volume of drug administered is 1 to 3 mL, with a 20- to 23-gauge, 1$\frac{1}{4}$- to 2$\frac{1}{2}$-inch needle. Slightly angle the needle toward the iliac crest.
- *Dorsogluteal* (Figure 13-16).* Volume of drug administered is 1 to 3 mL; 5 mL gamma globulin with 18- to 23-gauge, 1$\frac{1}{4}$- to 3-inch needle. Place the needle at a 90-degree angle to the skin with the patient in the prone position.
- *Deltoid* (Figure 13-17). Volume of drug administered is 0.5 to 1 mL, with a 23- to 25-gauge, $\frac{5}{8}$ to 1$\frac{1}{2}$-inch needle. Place the needle at a 90-degree angle to the skin or slightly toward the acromion.
- *Vastus lateralis* (Figure 13-18). Volume of drug administered is 0.5 mL in infants (max = 1 mL), 1 mL in pediatric patients, and 1 to 1.5 mL in adults (max = 2 mL). Direct the needle at the knee at a 45- to 60-degree angle to the frontal, sagittal, and horizontal planes of the thigh.

Z-Track Injection Technique

This technique (Figure 13-19) prevents medication from leaking back into the subQ tissue. It is frequently advised for medications that cause visible and permanent skin discolorations (e.g., iron dextran). The gluteal site is preferred. Using aseptic technique, draw up the medication. Replace the first needle with a second needle of appropriate gauge and length to penetrate muscle tissue and deliver the medication to the selected site. The first needle is removed to prevent the medication adhering to the needle shaft from being taken into the subQ tissue. Consider having the medication prepared in the pharmacy.

Intravenous

Action

- Systemic effect
- More rapid than IM or subQ routes

---

*The dorsogluteal site was used in the past for intramuscular injections; however, scientific evidence shows that the exact location of the sciatic nerve varies from person to person and this site is no longer used for that reason. If a needle hits the sciatic nerve, it could cause severe damage.

TABLE 13-1 INTRAMUSCULAR INJECTION SITES: PATIENT POSITION, ADVANTAGES, AND DISADVANTAGES

SITE	PATIENT POSITION	ADVANTAGES	DISADVANTAGES
Ventrogluteal	Supine, lateral	Anatomic landmarks well defined Muscle mass suited for deep IM or Z-track injections Free of major nerves	In the event of hypersensitivity reaction, medication absorption cannot be delayed by tourniquet
Deltoid	Lateral, prone, sitting, supine	Readily accessible In the event of hypersensitivity reaction, medication absorption can be delayed by tourniquet	Small muscle mass; limited to small volume doses Close to nerves; requires accurate technique
Vastus lateralis	Sitting, supine	Good site for infants Size acceptable for multiple injections Free of major nerves	Special attention required to avoid sciatic nerve or femoral structures if long needle is used

IM, Intramuscular.

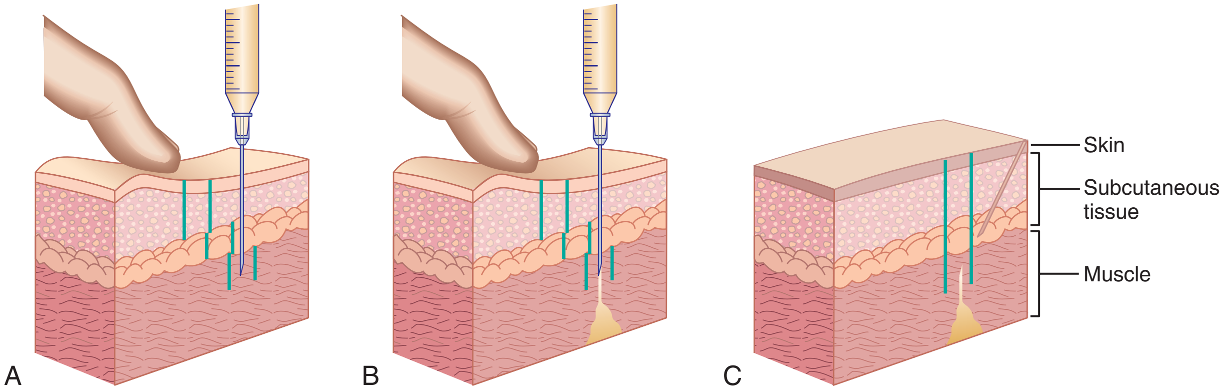

FIGURE 13–19 Z-track injection. **A,** Pull skin to one side and hold; insert needle. **B,** Holding skin to the side, inject medication. **C,** Wait 6 to 10 seconds before withdrawing needle and releasing skin. This technique prevents medication from entering subcutaneous tissue.

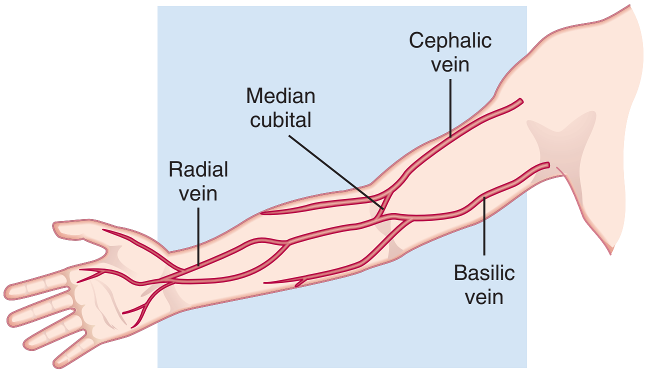

FIGURE 13–20 Common sites for intravenous administration.

Sites. Accessible peripheral veins (e.g., cephalic or cubital vein of arm; dorsal vein of hand) are preferred (Figure 13-20). When possible, ask the patient about preference. Avoid needless body restriction. In newborns, the veins of the feet, lower legs, and head may also be used after the previous sites have been exhausted.

Equipment

- Needle
- Adults: 20- to 21-gauge, 1 to 1½ inches
- Infants: 24-gauge; 1 inch
- Children: 22-gauge; 1 inch
- Larger bore for viscous drugs, whole blood or fractions; large volume for rapid infusion
- Electronic IV delivery device, an infusion controller, or pump
- Patient-controlled analgesia (PCA) system, if ordered
- Eutectic mixture of local anesthetics (EMLA), if appropriate

Technique

- Wash hands and wear gloves.
- Apply a tourniquet.
- Apply EMLA 1 hour before procedure on unbroken skin.
- Cleanse the area using aseptic technique with an appropriate solution.
- Insert butterfly or a catheter and feed up into the vein until blood returns. Remove tourniquet.
- Stabilize the needle or IV catheter, and apply dressing to site.

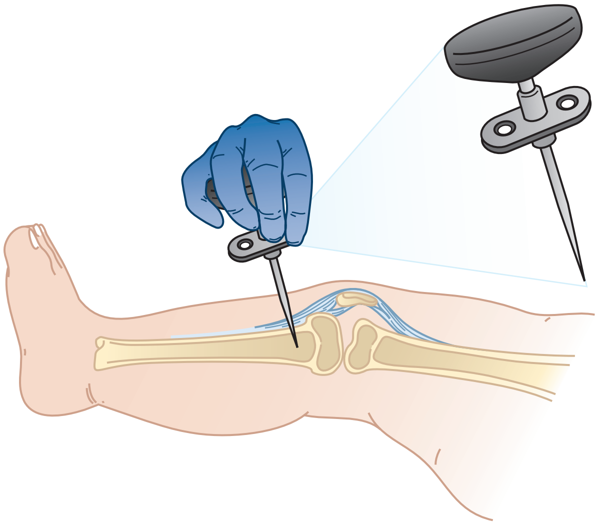

FIGURE 13–21 Intraosseous access.

- Monitor flow rate, distal pulses, skin color and temperature, and insertion site.
- Consult agency policy regarding addition of medications to bottle or bag, piggyback technique, and IV push. Be alert that all tubing is connected correctly.

Intraosseous

Action

- Fluids, crystalloids, blood products, and medications administered via intraosseous (IO) infusion into the bone marrow enter circulation through the network of venous sinusoids (Figure 13-21). IO is used when IV access is not possible; it is removed within 24 hours. Contraindications include fracture in insertion limb, infection at insertion site, severe osteoporosis and other bone abnormalities, and prosthetic joints in close proximity to insertion site.

Sites

- BIG: proximal tibia and humerus
- EZ-IO: proximal and distal tibia and humerus
- FAST1: sternum

Equipment

- Common intraosseous devices include BIG (blue cap for adults and red cap for children); EZ-IO; and First Access for Shock and Trauma I (FAST1)

Technique

- Wash hands and wear gloves.
- Palpate insertion site.
- Cleanse area using aseptic technique.
- Use insertion process appropriate to device (manual pressure, battery-operated power driver).
- Right after patency is confirmed, instill 1% lidocaine (usually 2 to 4 mL) if patient is awake.
- Stabilize the needle/device.
- Attach intravenous extension set; flush with isotonic saline (usually 5 to 10 mL), and attach IV tubing.

NURSING IMPLICATIONS FOR ADMINISTRATION OF PARENTERAL MEDICATIONS

Sites

- Ventrogluteal site is preferred for IM injections in adults and toddlers with gluteal muscle development associated with firmly established walking.
- For toddlers not walking alone for at least 1 year, the vastus lateralis is preferred.
- Do not use the dorsogluteal site for IM injections in children.

Equipment

- The syringe size should approximate the volume of medication to be administered.
- Use the tuberculin syringe for amounts <0.5 mL.
- Use the filter needle to draw up the medication from a glass vial or ampule. Change the needle before administration to prevent tissue irritation from any glass fragment or medication left on the needle.

Technique

- Wash hands and wear gloves.
- Correctly identify the patient.
- Explain to the patient what is going to be done. Gain the patient's cooperation. Allow the patient time to cooperate, if possible.
- Demonstrate empathy and concern for patient and family. Allay anxiety, and encourage expression of feelings.
- Position the patient.
- Follow the rights of medication administration (see Chapter 12).
- Inspect the skin before each injection.
- Inject medication slowly to minimize tissue damage.
- Stabilize skin during needle removal to reduce pain.
- Do not administer injections if sites are inflamed, edematous, or lesioned (e.g., moles, scars).
- Rotate the injection site to enhance absorption of the drug. Document the injection site.
- Observe patient for drug effectiveness. Report any untoward reactions immediately.
- Multiple products are available to reduce pain of parenteral medication administration, such as EMLA, lidocaine, and tetracaine in topical patch, and "shot buster"—a mechanical device based on the gate control theory of pain management.

DEVELOPMENTAL NEEDS OF PEDIATRIC PATIENTS

Anticipate developmental needs. Examples of needs associated with administration of medications include the following (refer to Chapter 7 for additional examples):

- Stranger anxiety (infant): Act to instill a sense of safety and security in the infant.

- Hospitalization, illness, or injury viewed as punishment (3 to 6 years of age): Allow control where appropriate; obtain child's view of situation; encourage positive relationships and expression of feelings in acceptable manner and activities. Include family or support person if appropriate.
- Fear of mutilation (3 to 6 years of age): Explain procedures carefully; use less intrusive routes, such as the oral route, whenever possible; allow children to give "play" injections to a doll or stuffed animal.

TECHNOLOGICAL ADVANCES

Advances in drug administration therapy continue to enhance safety, increase accessibility to sites, promote patient mobility, and improve patient adherence. Examples of these advances include the following:

- Pain-free delivery of insulin through patch
- Insulin pumps that deliver insulin based on monitoring of serum glucose levels
- Drugs implanted in contact lenses
- Intelligent infusion technology that programs IV infusions based on scanned information.
- Electronic order entry system
- Computerized unit dose dispensing cabinets
- Bar code technologies that scan medications and reconcile them with patient ID band
- Electronic medication administration records

SAFETY: Preventing Medication Errors

Medication Administration

- Remove foil-backed patches before magnetic resonance imaging (MRI) and in code situations when using AED equipment to prevent burns.
- Observe sterile technique when the skin is broken. Take precautions to avoid medication stains.
- Use firm strokes if the medication is to be rubbed in.

Nursing Process

Patient-Centered Collaborative Care

Overview of Medication Administration

Assessment

- Obtain appropriate vital signs and relevant laboratory test results for future comparisons and evaluation of therapeutic response.
- Determine patient's level of consciousness, risk for aspiration, and ability to take medications.
- Obtain drug history, including drug allergies.
- Identify high-risk patients for reactions.
- Assess patient's capability to follow therapeutic regimen.
- Assess possible contraindications in certain medication regimens.

Potential Nursing Diagnoses

- Risk for injury related to possible adverse reaction
- Readiness for enhanced management of medication regimen

Planning

- Identify goals.
- Promote therapeutic response, and prevent or minimize adverse reactions.
- Identify strategies to promote adherence.
- Identify interventions.

Nursing Interventions

- Prepare equipment and environment; wash hands.
- Check for allergies and other assessment data.
- Check drug label three times; check expiration date; apply rights of medication administration
- Be certain of drug calculation; verify dose with another RN or licensed personnel as necessary.
- Pour liquids at eye level on flat surface.
- Avoid contact with topical and inhalation preparations.
- Verify patient identification.
- Administer only drugs you have prepared.
- Assist the patient to appropriate position.
- Discard needles and syringes in "sharps" container. Do not recap needles.
- Keep all drugs stored properly, especially related to temperature, light, and moisture.
- Follow agency policy related to discarding drugs and controlled substances.
- Report drug errors immediately.
- Document all appropriate information in a timely manner.
- Record effectiveness of drugs administered, side effects or adverse effects, and reason for any drugs refused.

Patient Teaching

General

- Emphasize safety.
- Monitor patient's physical abilities regularly as needed.
- Keep or store medications in original labeled containers with child-resistant caps when needed.
- Provide patient and family with written instructions (or audio instructions if visually impaired or unable to read) about the drug regimen.
- Advise patient and family about expected therapeutic effect, anticipated onset of action, and expected duration of treatment.
- Educate patient and family on possible side effects or signs of an adverse reaction.
- Instruct patient and family about possible drug-laboratory test interaction.
- Advise patient of nonpharmacologic measures to promote therapeutic response.

- Encourage patient and family to have adequate supply of necessary medications available.
- Caution against use of OTC preparations, including herbal remedies without *first* contacting the health care provider.
- Reinforce importance of follow-up appointments with health care providers.
- Encourage patient to wear Medic-Alert band with medications or allergies indicated.
- Encourage lifestyle changes associated with medication administration, as needed (e.g., smoking cessation, exercising, limiting salt or fat in diet).
- Encourage use of community resources to assist with patient and family needs.

Diet

- Advise patient and family about possible drug-food interactions and contraindicated foods, if any.
- Advise patient and family about possible drug-alcohol interactions.

Self-Administration

- Advise patient and family regarding drug dose and dosing schedule.
- Teach patient and family about psychomotor skills related to drug regimen.
- Provide patient and family with contact information for questions and concerns.

Side Effects

- Counsel patient and family about general side effects and adverse reactions of the medications.
- Teach patient and family to monitor effects of drug, as appropriate (e.g., check blood pressure if drug is to treat hypertension).
- Advise patient and family when and how to notify health care provider.

Cultural Considerations

- Assess personal beliefs of patients and family.
- Modify communications to meet cultural needs of patient and family.
- Communicate respect for culture and cultural practices of patient and family.

Evaluation

- Evaluate effectiveness of medications administered.
- Identify expected time frame of desired drug response; consider modification of therapy as needed.
- Determine patient satisfaction with regimen.

KEY WEBSITES

The Institute for Safe Medication Practices: *www.ismp.org*

Medication Administration Safety: *www.ncbi.nlm.nih.gov/books/NBK2656/*

CDC's Medication Safety Program: *www.cdc.gov/medicationsafety/*

NCLEX STUDY QUESTIONS

1. The nurse is administering oral medications to a patient. Which are important considerations? (Select all that apply.)
   a. Administer irritating drugs with food.
   b. Avoid mixing medications in infant formula.
   c. Enteric-coated capsules may be chewed or crushed.
   d. Oral medications should be held if the patient is vomiting.
   e. Cut all transdermal patches to the correct dose.
2. The clinic nurse is preparing to administer an intradermal injection to the patient. Which supplies are most appropriate for this procedure?
   a. 21-gauge, $\frac{5}{8}$-inch needle
   b. 27-gauge, $\frac{5}{8}$-inch needle, 3-mL syringe
   c. 25-gauge needle, insulin syringe
   d. 25-gauge needle, tuberculin syringe
3. The nurse is administering iron dextran to a patient. What special considerations are associated with this?
   a. Gluteal site is preferred, best with different needle to draw up and to administer.
   b. Deltoid site is preferred; increased chance of "self sticks."
   c. Vastus lateralis site is preferred.
   d. Gluteal site is preferred with use of one needle.
4. The nurse administers a variety of medications to a patient. Which patient statement indicates a need for further teaching?
   a. "I do not drink or eat when I have sublingual nitroglycerin in place."
   b. "I mix all these meds in my dessert and hope I am not too full to finish."
   c. "I keep the meds in their original labeled containers."
   d. "I store medications away from children and pets."

5. The nurse is teaching a patient to use an inhaler. What common teaching point is essential for the nurse to include?
   a. Handheld nebulizers deliver a large molecule particle spray of medication.
   b. The semi- or high-Fowler's position is recommended.
   c. Spacers decrease delivery of medication.
   d. Nebulizers change medications to a fine powder mist.

6. A 3-year-old patient has an IM medication ordered. What is the most appropriate approach to gain the child's cooperation?
   a. Engage in fantasy play.
   b. Give a pretend injection to a toy animal.
   c. Restrain the patient's upper extremities.
   d. Ask family members to leave the room.

7. The nurse prepares to administer oral medications to a patient. What nursing intervention in addition to the "rights" is necessary to ensure safety?
   a. Assess the patient for risk for aspiration.
   b. Mix 2 of the 4 ordered medications into the meal.
   c. Administer drugs on a full stomach if food interferes with medication absorption.
   d. Administer irritating drugs without food to decrease gastrointestinal discomfort.

8. A patient is to start on a lidocaine transdermal patch. What is essential for the nurse to include in patient teaching? (Select all that apply.)
   a. Wear gloves when applying the patch.
   b. Cut the patch in half if a reduced dose is needed.
   c. Wear gloves when removing the patch.
   d. Remove the patch before an MRI.
   e. Remove the patch if the end becomes loose.

Answers: 1, a, b, d; 2, d; 3, a; 4, b; 5, b; 6, b; 7, a; 8, a, c, d.

UNIT III

Drug Calculations

Unit III (Chapter 14) provides practice in the calculation of drug dosages. The chapter is divided into six sections: (A) systems of measurement; (B) four general methods for calculating drug dosages, and two individualized methods; (C) calculations of oral dosages; (D) calculations of injectable dosages; (E) calculations of intravenous fluids; and (F) pediatric drug calculations. Although the sections in Chapter 14 are condensed, many practice problems are provided.

This unit may be used by students in place of a separate drug calculation text. It may also serve as a review of drug calculation when preparing for state boards or for nurses returning to practice settings.

CHAPTER 14

Medications and Calculations

OVERVIEW

This chapter on medications and calculations is subdivided into six sections: (A) systems of measurement with conversion, (B) methods for calculation, (C) calculations of oral dosages, (D) calculations of injectable dosages, (E) calculations of intravenous (IV) fluids, and (F) pediatric drug calculations. The nurse may proceed independently through Sections A to F to practice and master calculation of drug dosages during the fundamental nursing or pharmacology course. This chapter also serves as a review of drug calculation for nurses in practice settings.

Numerous drug labels are used in the drug calculation problems to familiarize the nurse with important information on a drug label. This information is then used in correctly calculating the drug dose.

Six calculation methods are explained. Four are general methods: (1) basic formula, (2) ratio and proportion, (3) fractional equation, and (4) dimensional analysis. The nurse should select one of these general methods for the calculation of drug dosages. The other two methods are used to individualize drug dosing by body weight and body surface area. Each calculation method has a color-coded icon that identifies the method used in the chapters.

The drug calculation chart in Table 14A-3 may be used in the clinical setting. The nurse might find it helpful to review Chapter 13 on medication administration.

Keeping in mind that the goal is to prepare and administer medications in a safe and correct manner, the following recommendations are offered:

- Think. Focus on each step of the problem. This applies to simple and difficult problems.
- Read accurately. Pay particular attention to the location of the decimal point and to the operation to be done, such as conversion from one system of measurement to another.
- Picture the problem.
- Identify an expected range for the answer.
- Seek to understand the problem. Do not merely master the mechanics of how to do it. Ask for help when unsure of the calculation.

Section 14A: Systems of Measurement with Conversion

OBJECTIVES

- Discuss the two systems of measurement.
- Convert measurement within the metric system, larger units to smaller units, and smaller units to larger units.
- Convert measurements within the household system, larger units to smaller units, and smaller units to larger units.
- Convert metric, apothecary, and household measurements among the three systems of measurement as appropriate. See Table 14A-3.

OUTLINE

Key Terms
Metric System

  Metric Conversion
Household System
  Household Conversion
Metric, Apothecary, and Household Equivalents

KEY TERMS

apothecary system, p. 150
gram, p. 149
household measurement, p. 149
liter, p. 149
meter, p. 149
metric system, p. 149
minim, p. 150
ounce, p. 149

Two systems of measurement—metric and household—are used to measure drugs and solutions. The metric system, developed in the late eighteenth century, is the internationally accepted system of measure. It is replacing the apothecary system, which dates back to the Middle Ages and had been used in England since the seventeenth century. Household measurement is commonly used in community and home settings in the United States.

METRIC SYSTEM

The **metric system** is a decimal system based on the power of 10. The basic units of measure are **gram** (g, gm, G, Gm) for weight; **liter** (l, L) for volume; and **meter** (m, M) for linear measurement, or length. Prefixes indicate the size of the units in multiples of 10. Table 14A-1 gives the metric units of measurement in weight (gram), volume (liter), and length (meter) in larger and smaller units that are commonly used.

Kilo is the prefix used for larger units (e.g., kilometer), and *milli, centi, micro,* and *nano* are the prefixes used for smaller units (e.g., millimeter). The prefix stands for a specific degree of magnitude; for instance, *kilo* stands for thousands, *milli* for one thousandth, *centi* for one hundredth, and so on. Because the difference between degrees of magnitude is always a multiple of 10, converting from one magnitude to another is relatively easy.

Conversion within the Metric System

The metric units most frequently used in drug notation are the following:

$$1\,\text{g} = 1000\,\text{mg}$$

$$1\,\text{L} = 1000\,\text{mL}$$

$$1\,\text{mg} = 1000\,\text{mcg}$$

To be able to convert a quantity, one of the values must be known, such as gram or milligrams, liters or milliliters, and milligrams or micrograms. Gram, liter, and meter are larger units; milligram, milliliter, and millimeter are smaller units.

TABLE 14A-1 METRIC UNITS OF MEASUREMENT

UNIT	NAMES AND ABBREVIATIONS	MEASUREMENTS
Gram (weight)	1 kilogram (kg, Kg)	1000 g
	1 gram (g, gm, G, Gm)	1 g
	1 milligram (mg)	0.001 g
	1 microgram (mcg)	0.000001 g
	1 nanogram (ng)	0.000000001 g
Liter (volume)	1 kiloliter (kl, KL)	1000 L (l)
	1 liter (L, l)	1 L (l)
	1 milliliter (mL)	0.001 L (l)
Meter (length)	1 kilometer (km)	1000 m
	1 meter (m, M)	1 m
	1 centimeter (cm)	0.01 m
	1 millimeter (mm)	0.001 m

NOTE: 1 mL (milliliter) = 1 cc (cubic centimeter). Values are the same in drug and fluid therapy. 1 mg (milligram) = 1000 mcg (micrograms).

Metric Conversion

A. When converting larger units to smaller units in the metric system, move the decimal point one space to the right for each degree of magnitude change.

Note: This does *not* apply to micro and nano units.

EXAMPLE

Change 1 gram to milligrams.

Grams are three degrees of magnitude greater than milligrams (see Table 14A-1). Move the decimal point three spaces to the right.

$$1\,\text{g} = 1.\underset{\curvearrowright}{000}\,\text{mg} \quad \text{or} \quad 1\,\text{g} = 1000\,\text{mg}$$

B. When converting smaller units to larger units in the metric system, move the decimal point one space to the left for each degree of magnitude of change.

EXAMPLE

Change 1000 milligrams to grams.

Milligrams are three degrees of magnitude smaller than grams. Move the decimal point three spaces to the left.

$$1000\,\text{mg} = 1.\underset{\curvearrowleft}{000}.\,\text{g} \quad \text{or} \quad 1000\,\text{mg} = 1\,\text{g}$$

REMEMBER: When changing larger units to smaller units, move the decimal point to the right, and when changing smaller units to larger units, move the decimal point to the left.

PRACTICE PROBLEM 1

Metric Conversion

Larger to Smaller Units	Smaller to Larger Units
1. Change 2 g to mg	4. Change 1500 mg to g
2. Change 0.5 (½) g to mg	5. Change 3 g to kg
3. Change 2.5 L to mL	6. Change 500 mL to L

HOUSEHOLD SYSTEM

Household measurement is not as accurate as the metric system because of the lack of standardization of spoons, cups, and glasses. The measurements are approximate. A teaspoon (t) is considered to be equivalent to 5 mL according to the official United States Pharmacopeia. Milliliters (mL) are the same as cubic centimeters (cc) in value. Three teaspoons equals 1 tablespoon (T). **Ounces** (oz) are fluid ounces in the household measurement system; the word *fluid* in front of

TABLE 14A-2 HOUSEHOLD EQUIVALENTS IN FLUID VOLUME

1 MEASURING CUP	=	8 OUNCES (oz)
1 medium-size glass (tumbler size)	=	8 ounces (oz)
1 coffee cup (c)	=	6 ounces (oz) (varies with cup size)
1 ounce (oz)	=	2 tablespoons (T)
1 tablespoon (T)	=	3 teaspoons (t)
1 teaspoon (t)	=	60 drops (gtt)*
1 drop (gt)*	=	1 **minim** (min, or m)

*Varies with viscosity of liquid and dropper opening.

ounce is usually not used. One milliliter of water fills a cubic centimeter exactly.

Table 14A-2 gives the household equivalents in fluid volume. The measurements with asterisks are frequently used in drug therapy and should be remembered.

Household Conversion

A. When converting larger units to smaller units within the household system, multiply the requested number by the basic equivalent value.

EXAMPLE

Change 2 glasses of water to ounces.

The equivalent value is 1 medium-sized glass = 8 oz (fl oz)

2 glasses × 8 oz = 16 oz (fl oz)

With discharge teaching for a patient who requires liquid medication(s) at home, the nurse may find it necessary to convert metric measurements to household measurements.

PRACTICE PROBLEM 2

Household Conversion

REMEMBER: To change larger units to smaller units, multiply the requested number of units by the basic equivalent value. To change smaller units to larger units, divide the requested number of units by the basic equivalent value. Refer to Table 14A-2 as needed.

Larger to Smaller Units

1. Change 3 oz to T _______
2. Change 5 T to t _______
3. Change 3 coffee cups to oz _______

Smaller to Larger Units

4. Change 3 T to oz _______
5. Change 16 oz to a measuring cup _______
6. Change 12 t to T _______

METRIC, APOTHECARY, AND HOUSEHOLD EQUIVALENTS

Although the **apothecary system** is no longer used, Table 14A-3 is included to show metric and apothecary equivalents by weight, and metric, apothecary, and household equivalents by volume.

PRACTICE PROBLEM 3

Summary: Metric and Household Measurements

Metric System: Refer to Table 14A-1 as needed.

1. 2 g = __________ mg
2. 1.2 kg = _________ g
3. 5 mg = ________ mcg
4. 2.5 L = ________ mL
5. 500 mg = __________ g
6. 10,000 mcg = ______ mg
7. 2400 mg = _________ g
8. 1500 mL = _________ L

Household System: Refer to Table 14A-2 as needed.

1. 5 glasses = ______ oz
2. 3 T = ___________ t
3. 2 c = __________ oz
4. 4 oz = _____________ T
5. 15 t = _____________ T
6. 5 T = _____________ oz

ANSWERS TO PRACTICE PROBLEMS

1 METRIC CONVERSION

1. $2.0\text{ g} = 2.\underbrace{000}\text{ mg}$ or 2.0 g = 2000 mg

   The gram is three degrees of magnitude greater than the milligram, so the decimal point is moved three spaces to the right.
2. $0.5\text{ g} = 0.\underbrace{500}\text{ mg}$ or 0.5 g = 500 mg

   The gram is three degrees of magnitude greater than the milligram, so the decimal point is moved three spaces to the right.
3. $2.5\text{ L} = 2.\underbrace{500}\text{ mL}$ or 2.5 L = 2500 mL

   The liter is three degrees of magnitude greater than the milliliter, so the decimal point is moved three spaces to the right.
4. $1500\text{ mg} = 1.\underbrace{500}.\text{ g}$ or 1500 mg = 1.5 g

   The milligram is three degrees of magnitude smaller (less) than the gram, so the decimal point is moved three spaces to the left.
5. $3\text{ g} = \underbrace{003}.\text{ kg}$ or 3 g = .003 mg

   The gram is three degrees of magnitude smaller than the kilogram, so the decimal point is moved three spaces to the left.
6. $500\text{ mL} = \underbrace{500}.\text{ L}$ or 500 mL = 0.5 L

   The milliliter is three degrees of magnitude smaller than the liter, so the decimal point is moved three spaces to the left.

2 HOUSEHOLD CONVERSION

1. 3 oz = 6 T;

   the equivalent value is 3 oz × 2 = 6 T
2. 5 T = 15 t;

   the equivalent value is 1 T = 3 t
3. 3 c = 18 oz;

   the equivalent value is 1 c = 6 oz
4. 3 T = 1½ oz;

   the equivalent value is 3 T ÷ 2 or 1½ oz
5. 16 oz = 2 c;

   the equivalent value is 1 measuring cup = 8 oz
6. 12 t = 4 T;

   the equivalent value is 1 T = 3 t

TABLE 14A-3 APPROXIMATE METRIC, APOTHECARY, AND HOUSEHOLD EQUIVALENTS

	METRIC SYSTEM		APOTHECARY SYSTEM	HOUSEHOLD SYSTEM
Weight	1 kg	1000 g	2.2 lb	2.2 lb
	*1 g	1000 mg	15 (16) gr	
	0.5 g	500 mg	7½ gr	
	0.3 g	300 (325) mg	5 gr	
	0.1 g	100 mg	1½ gr	
	*0.06 g	60 (65) mg	1 gr	
	0.03 g	30 (32) mg	½ gr	
	0.01 g	10 mg	⅙ gr	
		0.6 mg	1⁄100 gr	
		0.4 mg	1⁄150 gr	
		0.3 mg	1⁄200 gr	
Volume	1 L; 1000 mL		1 qt; 32 oz (fl oz)	
	0.5 L; 500 mL		1 pt; 16 oz (fl oz)	
	0.24 L; 240 mL		8 fl oz	1 glass
	0.18 L; 180 mL		6 fl oz	1 c
	*30 mL		1 fl oz; 8 fl dr	2 T; 6 t
	15 mL		½ fl oz; 4 fl dr	1 T; 3 t

2. 9 t
3. 12 oz
4. 8 T
5. 5 T
6. 2½ oz

Section 14B: Methods for Calculation

OBJECTIVES

- Select a formula—the basic formula, the ratio-and-proportion method, fractional equation, or dimensional analysis—for calculating drug dosages.
- Convert all measures to the same system and same unit of measure within the system before calculating drug dosage.
- Calculate drug dosage using one of the general formulas.
- Calculate drug dosage according to body weight and body surface area.
- Discuss meanings for abbreviations used in drug therapy.

OUTLINE

Interpreting Oral and Injectable Drug Labels
- Method 1: Basic Formula (BF)
- Method 2: Ratio and Proportion (RP)
- Method 3: Fractional Equation (FE)
- Method 4: Dimensional Analysis (DA)
- Method 5: Body Weight (BW)
- Method 6: Body Surface Area (BSA)
- BSA with the Square Root

KEY TERMS

basic formula, p. 153
body surface area (BSA), p. 157
body weight (BW), p. 156
dimensional analysis (DA), p. 155
drug label, p. 152
fractional equation, p. 154
ratio and proportion, p. 153

The four general methods for the calculation of drug doses are (1) basic formula, (2) ratio and proportion, (3) fractional equation, (4) and dimensional analysis. These methods are used to calculate oral and injectable drug doses. The nurse should select one of the methods to calculate drug doses and use that method consistently.

For drugs that require individualized dosing, calculation by body weight (BW) or by body surface area (BSA) may be necessary. In the past, these two methods, (5) and (6), have been used for the calculation of pediatric dosages and for drugs used in the treatment of cancer (antineoplastic drugs). BW and BSA methods of calculation are especially useful for individuals whose BW is low, who are obese, or who are older adults.

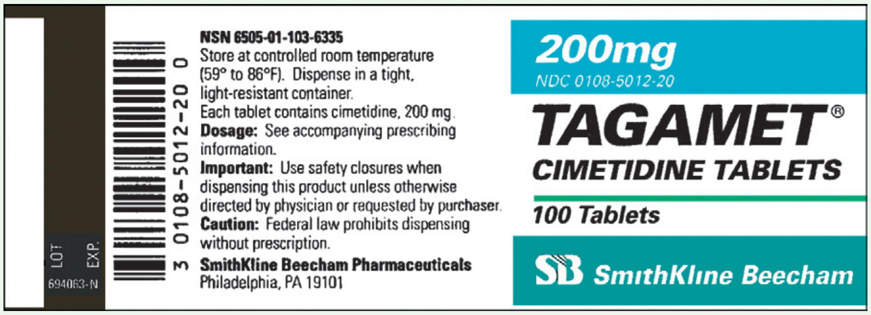
Before calculating drug doses, all units of measure must be converted to a single system (see Section 14A). It is most helpful to convert to the system used on the **drug label**. If the drug is ordered in grams (g, G) and the drug label gives the dose in milligrams (mg), then convert grams to milligrams (the measurement on the drug label) and proceed with the drug calculation. Nursing programs prefer to use only the metric system for drug calculations.

INTERPRETING ORAL AND INJECTABLE DRUG LABELS

Pharmaceutic companies usually label their drugs with the brand name of the drug in large letters and the generic name in smaller letters. The dose per tablet, capsule, or liquid (for oral and injectable doses) is printed on the drug label. Two examples of drug labels are given below, the first for an oral drug and the second for an injectable drug.

EXAMPLE 1 Oral Drug

Tagamet is the brand (trade) name, cimetidine is the generic name, and the dose is 200 mg/tablet.



LOT EXP.
694063-N

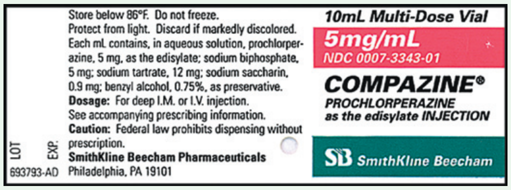
3 0108-5012-20 0

NSN 6505-01-103-6335
Store at controlled room temperature (59° to 86°F). Dispense in a tight, light-resistant container.
Each tablet contains cimetidine, 200 mg.
Dosage: See accompanying prescribing information.
Important: Use safety closures when dispensing this product unless otherwise directed by physician or requested by purchaser.
Caution: Federal law prohibits dispensing without prescription.
SmithKline Beecham Pharmaceuticals
Philadelphia, PA 19101

200mg
NDC 0108-5012-20
TAGAMET®
CIMETIDINE TABLETS
100 Tablets
SB SmithKline Beecham

EXAMPLE 2 Injectable Drug

Compazine is the brand (trade) name, prochlorperazine is the generic name, and the dose is 5 mg/mL injectable.



Store below 86°F. Do not freeze.
Protect from light. Discard if markedly discolored.
Each mL contains, in aqueous solution, prochlorperazine, 5 mg, as the edisylate; sodium biphosphate, 5 mg; sodium tartrate, 12 mg; sodium saccharin, 0.9 mg; benzyl alcohol, 0.75%, as preservative.
Dosage: For deep I.M. or I.V. injection.
See accompanying prescribing information.
Caution: Federal law prohibits dispensing without prescription.
SmithKline Beecham Pharmaceuticals
Philadelphia, PA 19101

LOT EXP.
693793-AD

10mL Multi-Dose Vial
5mg/mL
NDC 0007-3343-01
COMPAZINE®
PROCHLORPERAZINE as the edisylate INJECTION
SB SmithKline Beecham

METHOD 1: BASIC FORMULA (BF)

The **basic formula** is easy to recall and is most frequently used in calculating drug dosages. The basic formula is the following:

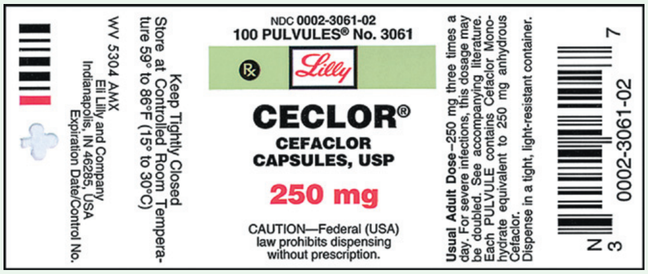
$$\frac{D}{H} \times V = A$$

where D is the desired dose (i.e., drug dose ordered by the health care provider),
H is the on-hand dose (i.e., drug dose on label of container [bottle, vial]),
V is the vehicle (i.e., drug form in which the drug comes [tablet, capsule, liquid]), and
A is the amount calculated to be given to the patient.

Examples

1. Order: cefaclor (Ceclor) 0.5 g PO b.i.d.

   Available:



NDC 0002-3061-02
100 PULVULES® No. 3061
℞ Lilly
CECLOR®
CEFACLOR CAPSULES, USP
250 mg
CAUTION—Federal (USA) law prohibits dispensing without prescription.

Keep Tightly Closed
Store at Controlled Room Temperature 59° to 86°F (15° to 30°C)
WV 5304 AMX
Eli Lilly and Company
Indianapolis, IN 46285, USA
Expiration Date/Control No.

Usual Adult Dose—250 mg three times a day. For severe infections, this dosage may be doubled. See accompanying literature.
Each PULVULE contains Cefaclor Monohydrate equivalent to 250 mg anhydrous Cefaclor.
Dispense in a tight, light-resistant container.

N 3 0002-3061-02 7

a. The unit of measure that is ordered (grams) and the unit on the bottle (milligrams) are from the same system of measurement—the metric system. Conversion to the same unit is necessary to work the problem. Because the bottle is in milligrams, convert grams to milligrams.

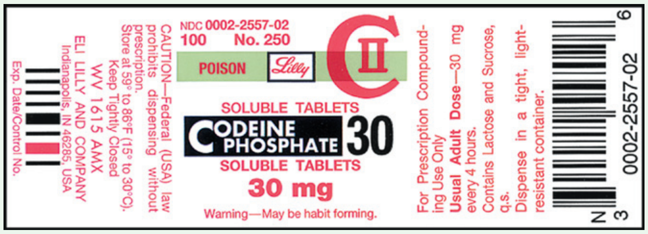
   To convert grams (large value) to milligrams (smaller value), move the decimal point three spaces to the right (see Section 14A: Systems of Measurement with Conversion).

$$0.5\text{ g} = 0.\underset{\curvearrowright}{500}\text{ mg or } 500\text{ mg}$$

b. $\frac{D}{H} \times V = \frac{500}{250} \times 1\text{ capsule} = \frac{500}{250} = 2\text{ capsules}$

2. Order: codeine 60 mg PO STAT

   Available:



NDC 0002-2557-02
100 No. 250
POISON Lilly
C II
SOLUBLE TABLETS
CODEINE PHOSPHATE 30
SOLUBLE TABLETS
30 mg
Warning—May be habit forming.

CAUTION—Federal (USA) law prohibits dispensing without prescription.
Store at 59° to 86°F (15° to 30°C).
Keep Tightly Closed
WV 1615 AMX
ELI LILLY AND COMPANY
Indianapolis, IN 46285, USA
Exp. Date/Control No.

For Prescription Compounding Use Only
Usual Adult Dose—30 mg every 4 hours.
Contains Lactose and Sucrose, q.s.
Dispense in a tight, light-resistant container.

N 3 0002-2557-02 6

a. $\frac{D}{H} \times V = \frac{60}{30} \times 1\text{ tablet} = \frac{60}{30} = 2\text{ tablets}$

METHOD 2: RATIO AND PROPORTION (RP)

The **ratio and proportion** method is the oldest method currently used in the calculation of drug dosages. The formula is as follows:

$$\underbrace{\overset{\text{Known}}{H : \underbrace{V :: D}_{\text{means}}} \overset{\text{Desired}}{: x}}_{\text{extremes}}$$

$$x =$$

where *H* is the drug on hand (available),
V is the vehicle or drug form (tablet, capsule, liquid),
D is the desired dose (as ordered),
x is the unknown amount to give,
and :: stands for "as" or "equal to."

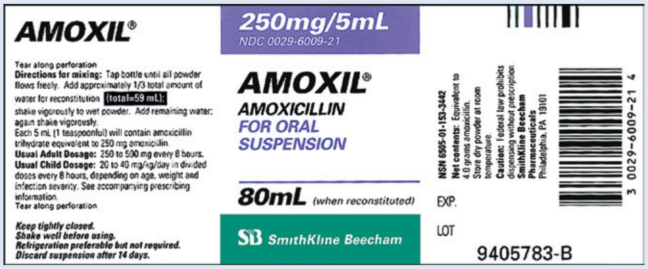
Multiply the means and the extremes. Solve for *x; x* is the divisor.

Continued

Examples

1. Order: amoxicillin (Amoxil) 100 mg PO q.i.d.

   Available:



AMOXIL®

Tear along perforation
Directions for mixing: Tap bottle until all powder flows freely. Add approximately 1/3 total amount of water for reconstitution (total=59 mL); shake vigorously to wet powder. Add remaining water; again shake vigorously.
Each 5 mL (1 teaspoonful) will contain amoxicillin trihydrate equivalent to 250 mg amoxicillin.
Usual Adult Dosage: 250 to 500 mg every 8 hours.
Usual Child Dosage: 20 to 40 mg/kg/day in divided doses every 8 hours, depending on age, weight and infection severity. See accompanying prescribing information.
Tear along perforation

Keep tightly closed.
Shake well before using.
Refrigeration preferable but not required.
Discard suspension after 14 days.

250mg/5mL
NDC 0029-6009-21

AMOXIL®
AMOXICILLIN
FOR ORAL SUSPENSION

80mL *(when reconstituted)*

SB SmithKline Beecham

NSN 6505-01-153-3442
Net contents: Equivalent to 4.0 grams amoxicillin.
Store dry powder at room temperature.
Caution: Federal law prohibits dispensing without prescription.

Philadelphia, PA 19101

EXP.

LOT

3 0029-6009-21 4

9405783-B

   a. Conversion is not needed because both are expressed in the same unit of measure.

   b. H : V :: D : x

   250 mg : 5 ml :: 100 mg : x mL

   means

   extremes

   $$250x = 500$$
   $$x = 2\text{ mL}$$

Answer: amoxicillin 100 mg = 2 mL

2. Order: aspirin/ASA 600 (650) mg q4h PRN

   Available: aspirin 325 mg/tablet

   H : V :: D : x

   325 mg : 1 tab :: 600 (650) mg : x

   $$325x = 600\ (650)$$
   $$x = 1.8\text{ tablets or 2 tablets}$$

   (round off or use 650 instead of 600)

   Answer: aspirin 650 mg = 2 tablets

METHOD 3: FRACTIONAL EQUATION (FE)

The **fractional equation** method is similar to ratio and proportion except it is written as a fraction.

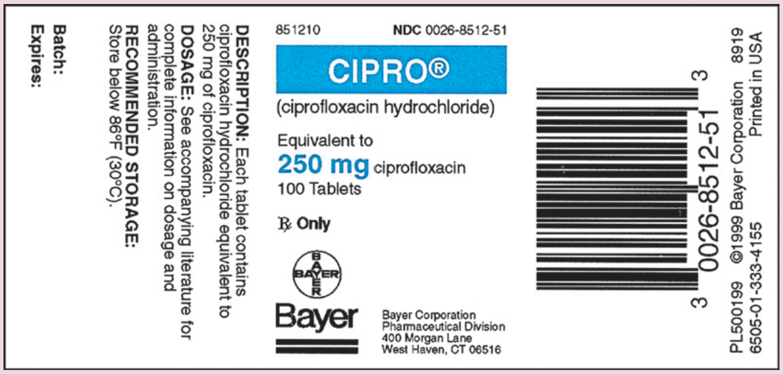
$$\frac{H}{V}=\frac{D}{X}\qquad\frac{\text{H dosage on hand}}{\text{V Vehicle}}=\frac{\text{D desired dosage}}{X\text{ unknown}}$$

Cross-multiply and solve for x.

Examples

Order: ciprofloxacin (Cipro) 500 mg PO q12h

Available:



DESCRIPTION: Each tablet contains ciprofloxacin hydrochloride equivalent to 250 mg of ciprofloxacin.
DOSAGE: See accompanying literature for complete information on dosage and administration.
RECOMMENDED STORAGE:
Store below 86°F (30°C).

Batch:
Expires:

How many tablet(s) should the patient receive per dose?

Answer:

$$\frac{H}{V}=\frac{D}{X}\quad\frac{250\text{ mg}}{1\text{ tab}}=\frac{500\text{ mg}}{X\text{ tab}}$$

Cross-multiply and solve for x.

$250x = 500$

$x = 2$ tablets of Cipro per dose

METHOD 4: DIMENSIONAL ANALYSIS (DA)

Dimensional analysis (DA) is a calculation method known as units and conversions. The advantage of DA is that it decreases the number of steps required to calculate a drug dosage. It is set up as one equation.

Examples

1. Identify the unit/form (tablet, capsule, mL) of the drug to be calculated. If the drug comes in tablet, then tablet = (equal sign).
2. The known dose and unit/form from the drug label follows the equal sign.

   Order: amoxicillin 500 mg
   On the drug label: 250 mg per capsule

$$\text{capsule} = \frac{1\,\text{cap}}{250\,\text{mg}}$$

3. The mg (250 mg) is the denominator, and it must match the next numerator, which is 500 mg (desired dose or order). The NEXT denominator would be 1 (one) or blank.

$$\text{capsule} = \frac{1\,\text{cap} \times \overset{2}{\cancel{500}}\,\cancel{\text{mg}}}{\underset{1}{\cancel{250}}\,\cancel{\text{mg}} \times 1} =$$

4. Cancel out the mg, 250 and 500. What remains is the capsule and 2.

Answer: 2 capsules When conversion is needed between milligrams (drug label) and grams (order), then a conversion factor is needed, which appears between the drug dose on hand (drug label) and the desired dose (order).

Metric Equivalent

$$1\,\text{g} = 1000\,\text{mg}$$

$$1\,\text{mg} = 1000\,\text{mcg}$$

Examples

Order: amoxicillin 0.5 g, PO, q8h

Available: 250 mg = 1 capsule (drug label). A conversion is needed between g and mg. Remember that 250 mg is the denominator; therefore 1000 mg (conversion factor, which is 1000 mg = 1 g) is the NEXT numerator, and 1 g becomes the NEXT denominator. The third numerator is 0.5 g, and the denominator is 1 (one) or blank.

$$\text{cap} = \frac{1\,\text{cap}}{250\,\cancel{\text{mg}}} \times \frac{1000\,\cancel{\text{mg}}}{1\,\text{g}} \times \frac{0.5\,\text{g}}{1} = \frac{500}{250} = 2\text{ caps of amoxicillin}$$

If conversion from grams to milligrams is not needed, the middle step can be omitted.

The following are formulas for dimensional analysis (DA):

$$\text{V (form of drug)} = \frac{\text{V (drug form)}}{\substack{\text{H (on hand)}\\ \text{(Drug label)}}} \times \frac{\text{D (desired dose)}}{\substack{\text{1 or blank}\\ \text{(Drug label)}}}$$

$$\text{For conversion: v (form of drug)}$$

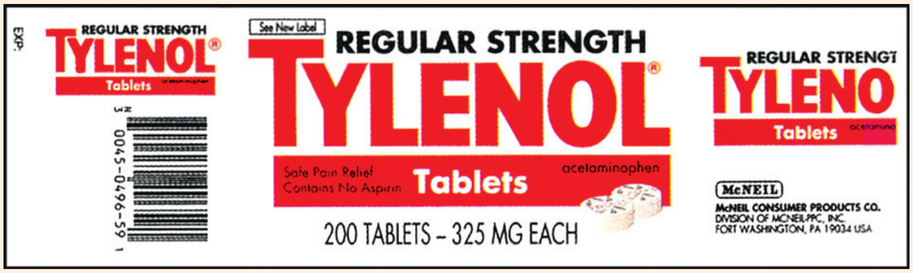
$$= \frac{\text{V (drug form)}}{\substack{\text{H (on hand)}\\ \text{(Drug label)}}} \times \frac{\text{C (H)}}{\substack{\text{C (D)}\\ \text{(Conversion factor)}}} \times \frac{\text{D (desired dose)}}{\substack{\text{1 or blank}\\ \text{(Drug order)}}}$$

As with other methods for calculation, the three components are D, H, and V. With dimensional analysis, the conversion factor is built into the equation and is included when the units of measurement of the drug order and the drug container differ. If the two are of the same units of measurement, the conversion factor is eliminated from the equation.

Examples

Order: acetaminophen (Tylenol) 1 g, PO, PRN

Available:



Factors: 325 mg = 1 tablet (from drug label)
1 g/1 (from drug order)
Conversion factor: 1000 mg = 1 g(G)
How many tablet(s) should be given? ______

$$\text{tab} = \frac{1\,\text{tab}}{325\,\cancel{\text{mg}}} \times \frac{1000\,\cancel{\text{mg}}}{\cancel{1}\,\text{g}} \times \frac{\cancel{1}\,\text{g}}{1} = \frac{1000}{325} = 3.07\text{ tab or 3 tab}$$

METHOD 5: BODY WEIGHT (BW)

The **body weight** (BW) method of calculation allows for the individualization of the drug dose and involves the following three steps:

1. Convert pounds to kilograms if necessary (lb ÷ 2.2 = kg).
2. Determine drug dose per BW by multiplying as follows:

$$\text{Drug dose} \times \text{body weight} = \text{patient's dose per day}$$

3. Follow the basic formula, ratio and proportion, fractional equation, or dimensional analysis method to calculate the drug dosage.

Examples

1. Order: fluorouracil (5-FU), 12 mg/kg/day IV, not to exceed 800 mg/day. The adult weighs 132 lb.
   a. Convert pounds to kilograms by dividing the number of pounds by 2.2 (1 kg = 2.2 lb).

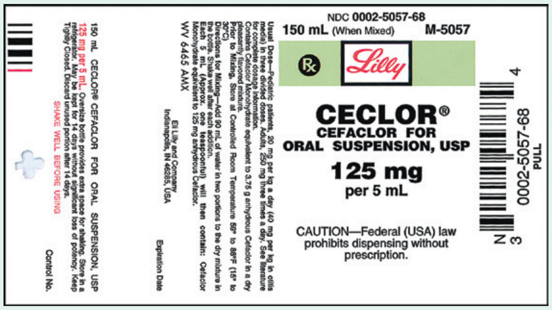
   $$132 \div 2.2 = 60\text{ kg}$$

   b. mg × kg = patient's dose

   $$12 \times 60 = 720\text{ mg IV/day}$$

   Answer: Fluorouracil 12 mg/kg/day = 720 mg
2. Order: cefaclor (Ceclor) 20 mg/kg/day in three divided doses. The patient weighs 31 lb.

   Available:



NDC 0002-5057-68
150 mL (When Mixed)

Lilly
CECLOR®
CEFACLOR FOR ORAL SUSPENSION, USP
125 mg per 5 mL
CAUTION—Federal (USA) law prohibits dispensing without prescription.
N 3 0002-5057-68 4
PULL

   a. Convert pounds to kilograms.

   $$31 \div 2.2 = 14\text{ kg}$$

   b. 20 mg × 14 g = 280 mg/day

   $$280\text{ mg} \div 3\text{ divided doses} = 93\text{ mg/dose}$$

   c. $\text{BF: } \frac{D}{H} \times V = \frac{93}{125} \times 5 = \frac{463}{125} = 3.7\text{ mL}$

or

$$\text{DA: ml} = \frac{5\text{ mL} \times 93\,\cancel{\text{mg}}}{125\,\cancel{\text{mg}} \times 1} = \frac{465}{125} = 3.7\text{ mL}$$

or

$$\begin{aligned}\text{RP: } & H : V :: D : x \\ & 125\text{ mg} : 5\text{ mL} :: 93\text{ mg} : x\text{ mL} \\ & 125x = 465 \\ & x = \frac{465}{125} = 3.7\text{ mL}\end{aligned}$$

or

$$\text{FE: } \frac{H}{V} = \frac{D}{x} \quad \frac{125}{5} = \frac{93}{x} =$$

$$\text{cross-multiply } 125x = 465$$

$$x = 3.7\text{ mL}$$

Answer: cefaclor 20 mg/kg/day = 3.7 mL per dose

METHOD 6: BODY SURFACE AREA (BSA)

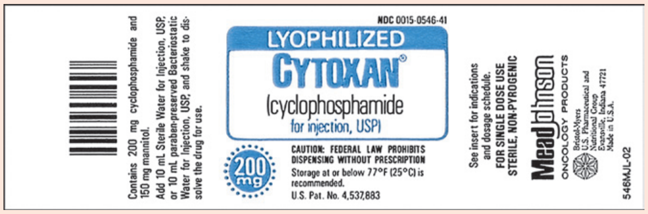
The **body surface area** (BSA) method is considered the most accurate way to calculate the drug dose for infants, children, older adults, and patients who are on antineoplastic agents or whose BW is low. The BSA, in square meters (m^2), is determined by where the person's height and weight intersect the nomogram scale (Figures 14B-1 [children] and 14B-2 [adults]). To calculate the drug dosage using the BSA method, multiply the drug dose ordered by the number of square meters.

$$100\,\text{mg} \times 1.8\,\text{m}^2\ (\text{BSA}) = 180\,\text{mg/day}$$

Examples

1. Order: cyclophosphamide (Cytoxan) 100 mg/m^2/day, IV

   Available:



Contains 200 mg cyclophosphamide and 150 mg mannitol.
Add 10 mL Sterile Water for Injection, USP, or 10 mL paraben-preserved Bacteriostatic Water for Injection, USP, and shake to dissolve the drug for use.

ONCOLOGY PRODUCTS
Bristol-Myers
U.S. Pharmaceutical and Nutritional Group
Evansville, Indiana 47721
Made in U.S.A.
546MJL-02

   Patient is 70 inches tall and weighs 160 lb.

   a. 70 inches and 160 lb intersect the nomogram scale at 1.97 m^2 (BSA)

   b. 100 mg × 1.97 = 197 mg.

Answer: Administer cyclophosphamide 197 mg or 200 mg/day.

2. Order: mephenytoin (Mesantoin) 200 mg/m^2 PO in three divided doses. Patient is 42 inches tall and weighs 44 lb.

   a. 42 inches and 44 lb intersect the nomogram scale at 0.8 m^2.

   b. 200 mg × 0.8 = 160 mg/day or 50 mg (53) t.i.d.

Answer: Administer mephenytoin 50 mg t.i.d.

BSA with the Square Root

BSA can be calculated by using the square root and a fractional formula of height and weight divided by a constant. Now that calculators are readily available, research has shown that this method results in fewer errors than drawing intersecting lines on a nomogram. The formula for BSA using the square root is as follows:

$$\text{BSA} = \sqrt{\frac{\text{height (inches)} \times \text{wt (lb)}}{3131\,(\text{constant})}}$$

Examples

Order: melphalan (Alkeran) 16 mg/m^2 q2wk. Patient is 68 inches tall and weighs 172 lb.

a. Use the BSA inches and pounds formula.

$$\text{BSA} = \sqrt{\frac{68\,\text{in} \times 172\,\text{lb}}{3131}}$$

$$\text{BSA} = \sqrt{\frac{11696}{3131}}$$

$$\text{BSA} = \sqrt{3.73}$$

$$\text{BSA} = 1.9\,\text{m}^2$$

b. 16 mg × 1.9 m^2 = 30.4 mg/m^2 or 30 mg/m^2. Patient should receive 30 mg every 2 weeks.

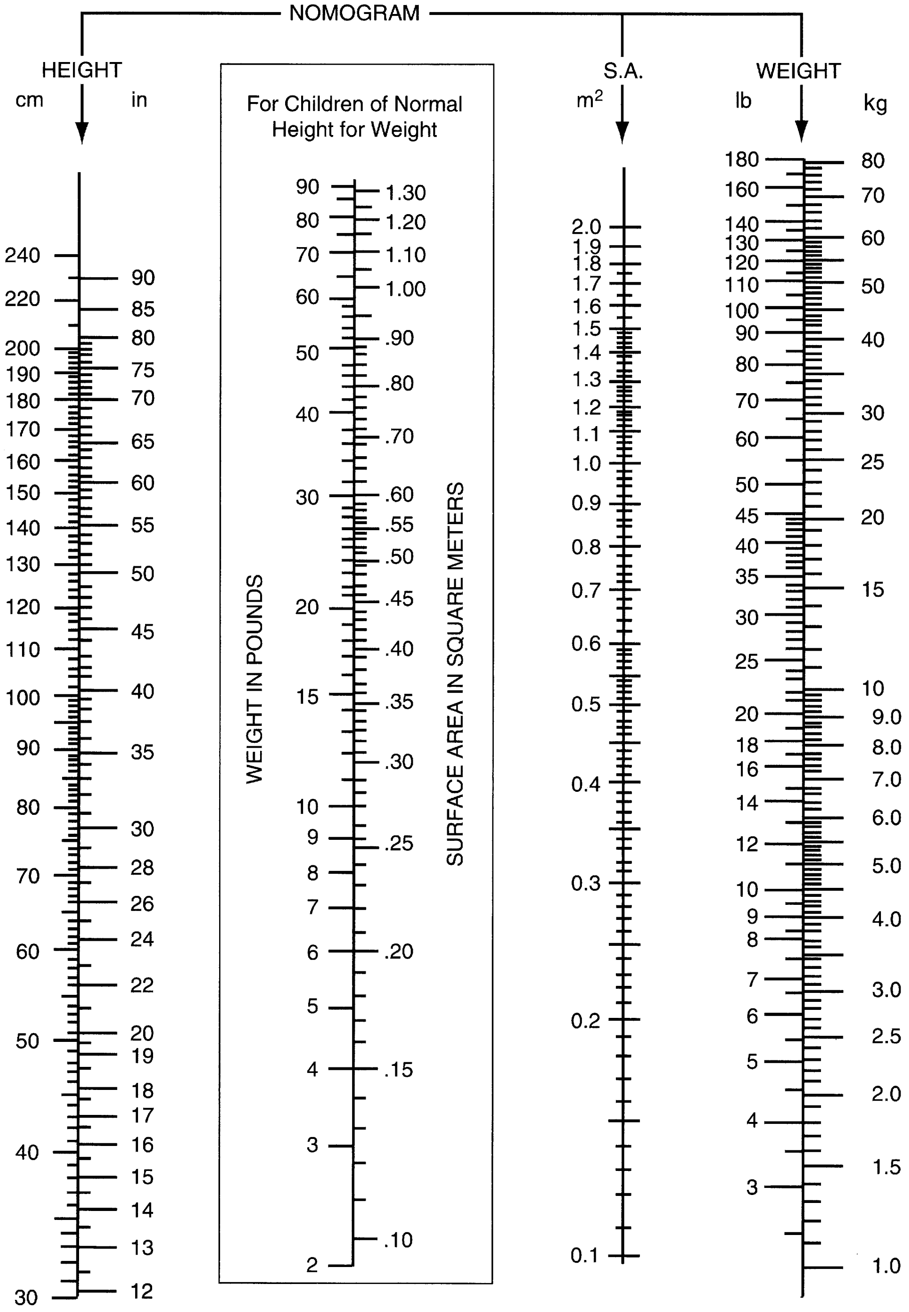

FIGURE 14B–1 West nomogram for infants and children. Directions: (1) Find height. (2) Find weight. (3) Draw a straight line that connects the height and weight. (4) Where the line intersects on the surface area column is the body surface area (m^2). (Modified from data by Boyd E, West CD. In Behrman RE, Kliegman RM, Jensen HB: *Nelson textbook of pediatrics,* ed. 18, Philadelphia, 2007, Saunders.)

ANSWERS TO PRACTICE PROBLEMS

1 DRUG DOSAGE USING BASIC FORMULA, RATIO AND PROPORTION, OR FRACTIONAL EQUATION

1. a. Convert grams to milligrams by moving the decimal point three spaces to the right.

$$0.4\text{ g} = 0\underbrace{.400}\text{ mg}$$

b. BF: $\frac{D}{H} \times V = \frac{400\text{ mg}}{400\text{ mg}} \times 1\text{ tablet} = 1\text{ tablet}$

2. a. Initially:

$$\text{BF: } \frac{D}{H} \times V = \frac{\overset{2}{\cancel{200}}}{\underset{1}{\cancel{100}}} \times 1 = 2\text{ tablets}$$

or

$$\begin{array}{lllllll} \text{RP:H} & : & \text{V} & :: & \text{D} & : & x \\ 100\text{ mg} & : & 1\text{ tab} & :: & 200\text{ mg} & : & x \end{array}$$

$$100x = 200$$

$$x = 2\text{ tablets}$$

or

FE (cross-multiply):

$$\frac{100}{1} = \frac{200}{x} =$$

$$100x = 200$$

$$x = 2\text{ tablets}$$

or

DA: No conversion factor

$$\text{Tablet(s)} = \frac{1 \quad \times \overset{2}{\cancel{200}}}{\underset{1}{\cancel{100}} \times 1} = 2\text{ tablets}$$

b. Daily:

$$\begin{array}{lllllll} \text{RP:H} & : & \text{V} & :: & \text{D} & : & x \\ 100\text{ mg} & : & 1\text{ tab} & :: & 50\text{ mg} & : & x \end{array}$$

$$100x = 50$$

$$x = \tfrac{1}{2}\text{ tablet}$$

DA: No conversion factor

$$\text{Tablet(s)} = \frac{1\text{ tab} \quad \times \overset{1}{\cancel{50}}\,\cancel{\text{mg}}}{\underset{2}{\cancel{100}}\,\cancel{\text{mg}} \times 1} = \tfrac{1}{2}\text{ tablet}$$

3. a. BF: $\frac{D}{H} \times V = \frac{\overset{5}{\cancel{250}}\,\cancel{\text{mg}}}{\underset{4}{\cancel{200}}\,\cancel{\text{mg}}} \times 5\text{ mL} =$

$$\frac{25}{4} = 6.25\text{ mL or } 6\text{ mL}$$

4. ½ tablet
5. 10 mL
6. FE: $\frac{H}{V} = \frac{D}{x} \quad \frac{62.5\text{ mg}}{5\text{ mL}} = \frac{100\text{ mg}}{x\text{ mL}}$

   (cross-multiply $62.5x = 500$)

$$x = 8\text{ mL}$$

7. 0.7 mL
8. a. 400 mcg/ml = 0.4 mg/ml

$$\frac{D}{H} \times V = \frac{0.4\text{ mg}}{0.4\text{ mg}} \times 1 = 1\text{ mL of atropine}$$

2 DRUG DOSAGE USING DIMENSIONAL ANALYSIS

9. a. 0.5 = 500 mg (move the decimal point 3 spaces to the right for milligrams)

   answer: 500 mg

   b. q 8h = 3 times a day; 500 mg × 3 = 1500 mg per day (0.5 g × 3 = 1.5 g per day)

   c. DA: $\text{tab} = \dfrac{1\text{ tab} \times 1000\text{ mg} \times 0.5\text{ g}}{250\text{ mg} \times 1 \times 1} = \dfrac{500}{250} = 2$ tablets of ERY-TAB

10. $\text{mL} = \dfrac{5\text{ mL} \times \overset{5}{\cancel{1000}}\ \cancel{\text{mg}} \times 0.4\ \cancel{\text{g}}}{\underset{1}{\cancel{200}}\ \cancel{\text{mg}} \times 1\ \cancel{\text{g}} \times 1} = 10\text{ mL}$

11. $\text{tab} = \dfrac{1\text{ tab} \times \overset{2}{\cancel{1000}}\ \cancel{\text{mg}} \times 0.5\ \cancel{\text{g}}}{\underset{1}{\cancel{500}}\ \cancel{\text{mg}} \times 1\ \cancel{\text{g}} \times 1} = 1\text{ tablet}$

3 DRUG DOSAGE USING BODY WEIGHT

12. a. 44 lb ÷ 2.2 kg = 20 kg

    b. 50 mg × 20 kg = 1000 mg/day

    1000 ÷ 4 times a day = 250 mg q.i.d. or q6h

13. a. 86 ÷ 2.2 = 39 kg

    b. 0.1 mg × 39 = 3.9 mg, or 4 mg (round to the whole number)

    4 ÷ 4 = 1 mg q6h

14. 33 ÷ 2.2 = 15 kg

    15 mg × 15 = 225 mg/day

    225 ÷ 2 times a day = 112.5 mg, q12h per dose

    $\dfrac{D}{H} \times V = \times \dfrac{112.5}{125} \times 5\text{ mL} = \dfrac{562.5}{125} = 4.5\text{ mL q12h}$

    a. Administer cefprozil 225 mg/day

    b. Administer 112.5 mg = 4.5 mL, q12h

4 DRUG DOSAGE USING BODY SURFACE AREA

15. 1.65 m^2

16. a. Patient's height and weight intersect the nomogram scale at 1.97 m^2.

    b. 20 Unit × 1.97 = 39.4, or 39 Unit (round to the whole number)

17. a. Height and weight intersect the nomogram scale at 0.98 m^2.

    b. 2 g × 0.98 = 1.96 g, or 2 g/day (round to the whole number)

    c. 5 mL (convert grams to milligrams)

    $0.5\text{ g} = 0.\underset{\curvearrowright}{500}\text{ mg or } 500\text{ mg}$

Section 14C: Calculations of Oral Dosages

OBJECTIVES

- Calculate oral dosages from tablets, capsules, and liquids with selected formula.
- Calculate oral medications according to body weight and body surface area.
- Calculate the amount of tube feeding solution needed for dilution according to the percentage ordered.

OUTLINE

Key Terms
Tablets, Capsules, and Liquids
Interpreting Oral Drug Labels
Drug Differentiation
  Preventing Medication Errors
Calculation for Tablet, Capsule, and Liquid Doses
Body Weight and Body Surface Area
Drugs Administered via Nasogastric Tube

KEY TERMS

body surface area (BSA), p. 157
capsules, p. 165
enteric-coated, p. 165
sustained-release, p. 165
tablets, p. 165
tube feeding, p. 173

Eighty percent of all drugs consumed are given orally. Oral drugs are available in tablet, capsule, powder, and liquid form. The written abbreviation for drugs given orally is P.O. or PO (*per os,* or *by mouth*). Oral medications are absorbed by the gastrointestinal (GI) tract, mainly from the small intestine.

Oral medications have the following advantages: (1) the patient frequently can take oral medications without assistance, (2) the cost of oral medications is usually less than when given via other routes (e.g., parenteral), and (3) oral medications are easy to store. The disadvantages include (1) variation in absorption as a result of food in the GI tract and pH variation of GI secretions, (2) irritation of the gastric mucosa by certain drugs (e.g., potassium chloride), and (3) destruction or partial inactivation of the drugs by liver enzymes. This section discusses oral dosages for adults; Section 14F discusses oral dosages for children.

TABLETS, CAPSULES, AND LIQUIDS

Tablets come in different forms and drug strengths. Most tablets are scored and thus can be readily broken when half of the drug amount is needed. **Capsules** are gelatin shells that contain powder or time-release pellets (beads). **Sustained-release** (pellet) capsules and controlled-release capsules *should not* be crushed and diluted, because the medication will be absorbed at a much faster rate than indicated by the manufacturer. Many medications that are in tablet form are also available in liquid form. When the patient has difficulty taking tablets, the liquid form of the medication is given. The liquid form can be in a suspension, syrup, elixir, or tincture. Some liquid medications that irritate the stomach, such as potassium chloride, are diluted. The tincture form is always diluted.

Enteric-coated (hard-shell) tablets must *not* be crushed, because the medication could irritate the gastric mucosa. Enteric-coated drugs pass through the stomach into the small intestine where the drug's coating dissolves and then absorption occurs. Oral drugs (tablets, capsules, liquids) that irritate the gastric mucosa should be taken with 6 to 8 ounces of fluids or taken with food. Figure 14C-1 shows the different forms of tablets and capsules.

Liquid medications are poured into a medicine cup that is calibrated in ounces, teaspoons, tablespoons, and milliliters. Figure 14C-2 shows the markings on a medicine cup.

INTERPRETING ORAL DRUG LABELS

Pharmaceutic companies usually label their drugs with the brand (trade) name of the drug in large letters and the generic name in smaller letters. The dose per tablet, capsule, or liquid is often printed under the drug name.

DRUG DIFFERENTIATION

Preventing Medication Errors

Some drugs' spellings look alike or sound alike but have different chemical drug structures and are prescribed for different health problems. When ordering drugs, make sure the spelling of the drug is correct, and be extremely careful when administering drugs whose names look alike. Caution: Physicians' handwriting of drug names.

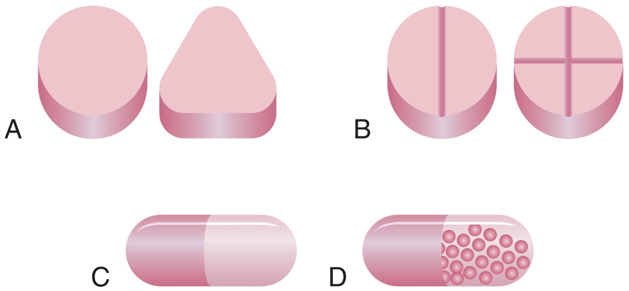

FIGURE 14C–1 Shapes of tablets and capsules. **A** and **B,** Tablets; **C** and **D,** capsules.

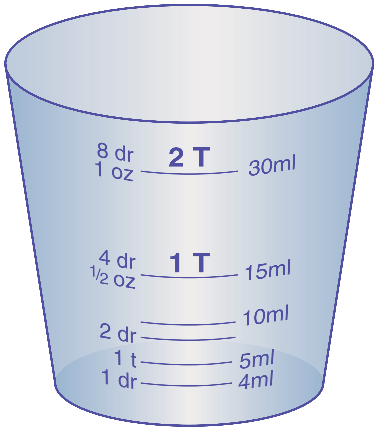

FIGURE 14C–2 Medicine cup for liquid measurement. (From Kee JL, Marshall SM: *Clinical calculations,* ed. 7, St. Louis, 2013, Elsevier.)

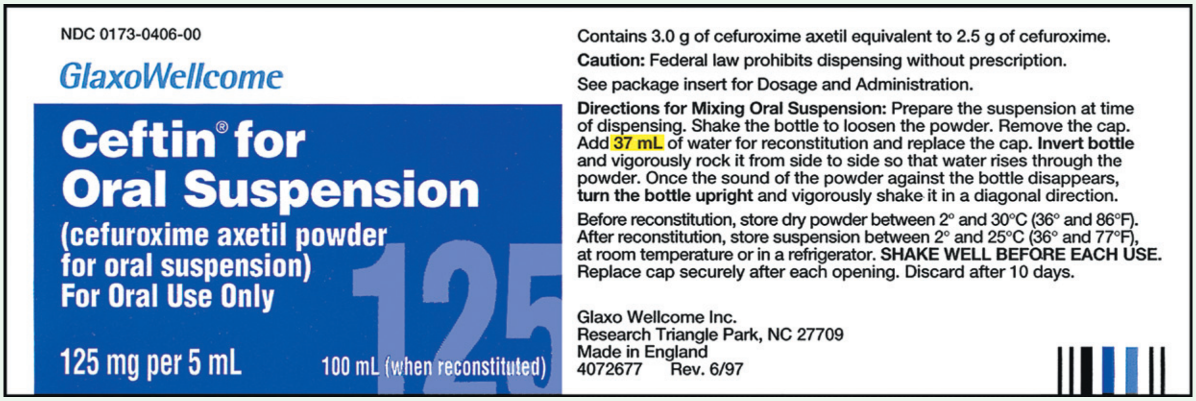
EXAMPLES

Ceftin is the brand (trade) name, and cefuroxime axetil is the generic name. The dose is 125 mg/5 mL (oral suspension).



NDC 0173-0406-00

GlaxoWellcome

Ceftin® for Oral Suspension

(cefuroxime axetil powder for oral suspension)

For Oral Use Only

125

125 mg per 5 mL

100 mL (when reconstituted)

Contains 3.0 g of cefuroxime axetil equivalent to 2.5 g of cefuroxime.

Caution: Federal law prohibits dispensing without prescription.

See package insert for Dosage and Administration.

Directions for Mixing Oral Suspension: Prepare the suspension at time of dispensing. Shake the bottle to loosen the powder. Remove the cap. Add **37 mL** of water for reconstitution and replace the cap. **Invert bottle** and vigorously rock it from side to side so that water rises through the powder. Once the sound of the powder against the bottle disappears, **turn the bottle upright** and vigorously shake it in a diagonal direction.

Before reconstitution, store dry powder between 2° and 30°C (36° and 86°F). After reconstitution, store suspension between 2° and 25°C (36° and 77°F), at room temperature or in a refrigerator. **SHAKE WELL BEFORE EACH USE.** Replace cap securely after each opening. Discard after 10 days.

Glaxo Wellcome Inc.
Research Triangle Park, NC 27709
Made in England
4072677 Rev. 6/97

EXAMPLE 1 Quinidine and Quinine

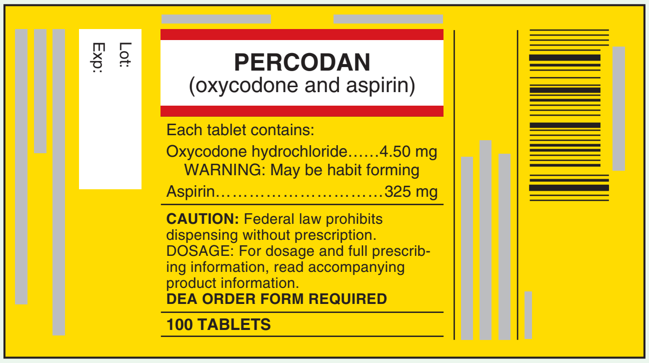
Quinidine is an antiarrhythmic drug, and quinine is an antimalarial drug. Read the drug label three times before pouring the drug.

EXAMPLE 2 Celebrex, Celexa, and Cerebyx

All three drugs are brand name drugs and have a similar spelling. Celebrex (celecoxib) is an analgesic, a cyclo-oxygenase 2 (COX-2) inhibitor; Celexa (citalopram) is an antidepressant, a selective serotonin reuptake inhibitor (SSRI); and Cerebyx (fosphenytoin sodium) is an anticonvulsant.

EXAMPLE 3 Percodan and Percocet

Percodan contains oxycodone and aspirin, and Percocet contains oxycodone and acetaminophen. A patient may be allergic to aspirin or should not take aspirin because of a stomach ulcer; therefore it is important that the patient take Percocet. Read the drug labels carefully.



Lot:
Exp:

PERCODAN
(oxycodone and aspirin)

Each tablet contains:
Oxycodone hydrochloride……4.50 mg
WARNING: May be habit forming
Aspirin…………………………325 mg

CAUTION: Federal law prohibits dispensing without prescription.
DOSAGE: For dosage and full prescribing information, read accompanying product information.
DEA ORDER FORM REQUIRED

Caution: Federal law prohibits dispensing without prescription.

See package insert for Dosage and Administration.

Directions for Mixing Oral Suspension: Prepare the suspension at time of dispensing. Shake the bottle to loosen the powder. Remove the cap. Add 19 mL of water for reconstitution and replace the cap. **Invert bottle** and vigorously rock it from side to side so that water rises through the powder. Once the sound of the powder against the bottle disappears, **turn the bottle upright** and vigorously shake it in a diagonal direction.

Before reconstitution, store dry powder between 2° and 30°C (36° and 86°F). After reconstitution, store suspension between 2° and 30°C (36° and 86°F), at room temperature or in a refrigerator. **SHAKE WELL BEFORE EACH USE.** Replace cap securely after each opening. Discard after 10 days.

Dosage: Administer every 12 hours. See accompanying prescribing information. ℞ only

Conversion factor: 1000 mg = 1 g

How many milliliters should the patient receive per dose? ______

BODY WEIGHT AND BODY SURFACE AREA

Calculating the drug dosage for adults by body weight (BW) and **body surface area** (BSA) is used mostly when administering drugs to treat cancer (antineoplastic drugs). These two individualized methods are also used frequently to calculate drug dosages for children. Examples and practice problems for pediatrics are given in Section 14F.

To use the body weight method, convert the patient's weight in pounds to kilograms (kg). To convert, divide pounds by 2.2 to equal kilograms. To use the body surface area (BSA) method, the person's weight and height and a nomogram are needed (see Sections 14B and 14F). Daily requirements are usually divided into two to four doses per day.

EXAMPLE

1. Order: cyclophosphamide (Cytoxan) 2 mg/kg PO daily. Patient weighs 143 lb.
   How much does the patient weigh in kilograms? ______
   How many milligrams should the patient receive? ______
   Answer: 143 lb ÷ 2.2 = 65 kg
   2 mg × 65 = 130 mg of cyclophosphamide daily

PRACTICE PROBLEM 2

Body Weight

1. Order: valproic acid (Depakene) 8 mg/kg/day in four divided doses. Patient weighs 165 lb.
   How much Depakene should be administered per dose? ______
2. Order: cyclophosphamide (Cytoxan) 4 mg/kg/day. Patient weighs 176 lb.
   How much should the patient receive per day? ______

ANSWERS TO PRACTICE PROBLEMS

1 ORAL MEDICATIONS USING BASIC FORMULA, RATIO AND PROPORTION, FRACTIONAL EQUATION, OR DIMENSIONAL ANALYSIS

1. 3 capsules of Sinequan
2. 2 tablets of Zestril
3. a. 600 mg

   b. BF: $\frac{D}{H} \times V = \frac{\overset{6}{\cancel{300\text{ mg}}}}{\underset{1}{\cancel{50\text{ mg}}}} \times 5\text{ mL} = 30\text{ mL per dose}$
   (twice a day = 60 mL)

   or

   RP: H : V :: D : X
   50 mg : 5 mL :: 300 mg : X mL
   $50X = 1500$
   $X = 30\text{ mL per dose}$
   (twice a day = 60 mL)

   or

   FE: $\frac{H}{V} = \frac{D}{x} = \frac{50\text{ mg}}{5\text{ mL}} = \frac{300\text{ mg}}{x} =$
   (cross-multiply) $50X = 1500$
   $X = 30\text{ mL per dose}$
   (twice a day = 60 mL)

   DA: $\text{mL} = \frac{5\text{ mL} \times \overset{6}{\cancel{300\text{ mg}}}}{\underset{1}{\cancel{50\text{ mg}}} \times 1} = 30\text{ mL per dose}$
   (twice a day = 60 mL)

4. 2 tablets

   a. BF: $\frac{D}{H}\times V=\frac{0.5}{0.25}\times 1=\underset{\curvearrowright}{0.25}\overset{2.0}{\sqrt{\underset{\curvearrowright}{0.50}\,0}}=2\text{ tablets}$

   or

   b. RP: $H : V :: D : x$

   $0.25\text{ mg} : 1\text{ tab} :: 0.5\text{ mg} : x\text{ tab}$

   $0.25x=0.5=2\text{ tablets}$

   c. DA: $\text{tab}=\frac{1 \quad \times 0.5\,\cancel{mg}}{0.25\,\cancel{mg}\times 1}=2\text{ tablets}$

5. 1 sublingual tablet

   Convert grains to milligrams. $\frac{1}{150}$ gr = 0.4 mg

6. a. Select Urecholine 10-mg bottle.

   b. BF: $\frac{D}{H}\times V=\frac{20\,\cancel{mg}}{10\,\cancel{mg}}\times 1\text{ tab}=\frac{20}{10}=2\text{ tablets}$

   or

   DA: $\text{tab}=\frac{1 \quad \times 20\,\cancel{mg}}{10\,\cancel{mg}\times 1}=2\text{ tablets}$

   No conversion needed

7. 20 mL of Augmentin suspension

8. $\frac{D}{H}\times V=\frac{6\text{ mg}}{4\text{ mg}}\times 5=\frac{30}{4}=7.5\text{ mL of Zofran}$

9. Select 5-mg tablets. Give two tablets.

10. a. b.i.d. = 2 times a day; $25\times 2=50$ mg per day

    b. RP: $H : V :: D : V$

    $12.5\text{ mg} : 1\text{ tab} :: 25\text{ mg} : X$

    $12.5\,X=25$

    $X=2$ tablets of Capoten

    DA: $\text{tab}=\frac{1 \quad \times 25\text{ mg}}{12.5\text{ mg}\times 1}=2\text{ tablets of Capoten}$

11. a. Select 25- to 250-mg strength.

    b. Give half a tablet.

    2 capsules DA: $\text{capsules}=\frac{1\text{ cap} \quad \times \overset{2}{\cancel{20}}\,\cancel{mg}}{\underset{1}{\cancel{10}}\,\cancel{mg}\times 1}=2\text{ capsules}$

12. a. BF: $\frac{D}{H}\times V=\frac{400\text{ mg}}{125\text{ mg}}\times 5\text{ mL}=\frac{2000}{125}=16\text{ mL using 125-mg Ceftin bottle}$

    FE: $\frac{H}{V}=\frac{D}{X}=\frac{250\text{ mg}}{5\text{ mL}}=\frac{400\text{ mg}}{X}=$

    (cross multiply) $250\,X=2000$

    $X=8$ mL using 250 mg Ceflin bottle

    b. Use the Cefltin bottle 250 mg/5 ml to give fewer milliliters Either bottle could be used.

13. DA: $\text{capsules}=\frac{1\text{ cap} \quad \times \overset{2}{\cancel{20}}\,\cancel{mg}}{\underset{1}{\cancel{10}}\,\cancel{mg}\times 1}=2\text{ capsules}$

14. 2.5 mL per dose

    $\text{mL}=\frac{5\text{ mL} \quad \times \overset{5}{\cancel{1000}}\,\cancel{mg}\cdot 0.1\,\cancel{g}}{\underset{1}{\cancel{200}}\,\cancel{mg}\times \quad 1\,\cancel{g} \quad \cdot 1}$

    $=2.5$ mL per dose

2 BODY WEIGHT

1. 75 kg; 150 mg/dose; 600 mg/day
2. 80 kg; 320 mg/day

DRUGS ADMINISTERED VIA NASOGASTRIC TUBE

Oral medications can be administered through a nasogastric tube but should not be mixed with the entire **tube feeding solution.** Mixing the medications in a large volume of tube feeding solution decreases the amount of drug the patient receives for a specific time. The medication (NOT time-released or sustained-release capsules and psyllium hydrophilic mucilloid [Metamucil]) should be diluted in 1 ounce (30 mL) of warm water unless otherwise instructed, administered through the tube, and followed with extra water to ensure that the drug reaches the stomach and is not left in the tube. Check the policy at your institution.

Section 14D: Calculations of Injectable Dosages

OBJECTIVES

- Describe the difference between vials and ampules.
- Describe the types of syringes and needles and their uses.
- Explain how to administer intradermal, subcutaneous, and intramuscular injections.
- Calculate the dosage of drugs for subcutaneous and intramuscular injections.
- Identify the amount of insulin dosage with the use of an insulin syringe.
- Explain the methods for mixing two insulins in one insulin syringe and for mixing two injectable drugs in one syringe.
- Describe the procedure for the preparation and calculation of medications in powdered form for injectable use.

OUTLINE

Key Terms

KEY TERMS

ampule, p. 174
bevel, p. 177
diluent, p. 181
gauge, p. 176
insulin syringe, p. 176
intradermal, p. 177
intramuscular (IM), p. 180
lumen, p. 176
parenteral, p. 174
subcutaneous (subQ), p. 177
tuberculin syringe, p. 175
vial, p. 174

When medications cannot be taken by mouth because of (1) an inability to swallow, (2) a decreased level of consciousness, (3) an inactivation of the drug by gastric juices, or (4) a desire to increase the effectiveness of the drug, the parenteral route may be the route of choice. **Parenteral** medications are administered intradermally (under the skin), subcutaneously (into the fatty tissue), intramuscularly (IM, within the muscle), and intravenously (IV, in the vein). IV injectables are discussed in Section 14E. The injectables in this section include intradermal, subQ (including insulin and heparin), and IM from prepared liquid and reconstituted powder in vials and ampules. Prefilled drug cartridges (syringes) are also discussed.

This section is divided into five parts: (1) injectable preparations, (2) intradermal injections, (3) subQ injections, (4) insulin injections, and (5) IM injections. Examples and practice problems to solve for the correct dosage are provided.

INJECTABLE PREPARATIONS

The appropriate drug container (vial or ampule) and the correct selection of needle and syringe are essential in the preparation of the prescribed drug dose. The route of administration is part of the medication order.

VIALS AND AMPULES

A **vial** is usually a small glass container with a self-sealing rubber top. Some are multiple-dose vials, and when properly stored, they can be used over time. An **ampule** is a glass container with a tapered neck for snapping open and using only once. Drugs that deteriorate readily in liquid form are packaged in powder form in vials and ampules for storage. Once the dry form of the drug is reconstituted (usually with sterile water, bacteriostatic water, or saline), the drug is used immediately or must be refrigerated. Check the accompanying drug circular for specific storage length and other instructions. The person reconstituting the drug should write on the label when the drug is to be discarded and include his or her initials. Usually a vial should be used within 96 hours.

Drug labels on vials and ampules provide the following information: (1) generic and brand name of the drug, (2) drug dose in weight (milligrams, grams, milliequivalents) and amount (milliliters), (3) expiration date, and (4) directions about administration. If the drug is in powdered form, mixing instructions and dose equivalents (e.g., milligrams equal milliliters) may be given. Figure 14D-1 shows a vial and an ampule.

SYRINGES

The syringe is composed of a barrel (outer shell), plunger (inner part), and the tip where the needle joins the syringe (Figure 14D-2). Syringes are available in various types and sizes, the most common of which are the 3-mL and 5-mL tuberculin, insulin, and metal and plastic syringes for prefilled cartridges. Glass syringes may be used in the operating room and on special instrument trays. The tip of the syringe and inside of the plunger should remain sterile.

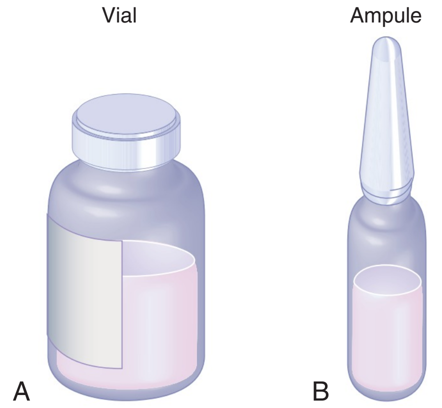

FIGURE 14D–1 **A,** Vial. **B,** Ampule. (From Kee JL, Marshall SM: *Clinical calculations,* ed. 7, St. Louis, 2013, Elsevier.)

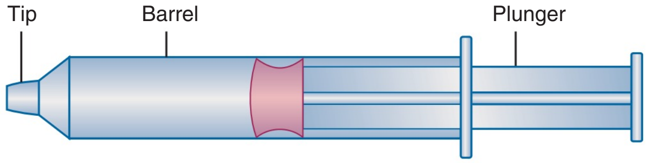

FIGURE 14D–2 Parts of a syringe. (From Kee JL, Marshall SM: *Clinical calculations,* ed. 7, St. Louis, 2013, Elsevier.)

The 3-mL syringe is calibrated in tenths (0.1 mL) and minims. The amount of fluid in the syringe is determined by the black rubber end of the plunger (the inner end of the plunger) that is closest to the tip (Figure 14D-3). REMEMBER: Milliliter (mL) and cubic centimeter (cc) may be used interchangeably, but milliliter (mL) is preferred. An advance in safety needle technology is the SafetyGlide shielding hypodermic needle (see Chapter 13). This type of needle reduces needlestick injuries.

The 5-mL syringe is calibrated in 0.2-mL marks. A 5-mL syringe is usually used when the fluid needed is more than 2.5 mL. It is frequently used when reconstituting the dry drug form with sterile bacteriostatic water or saline. The needleless syringes are used primarily for intermittent infusion therapy to irrigate the intermittent infusion device for maintaining patency and to administer IV medication through the IV tubing device. See intermittent infusion adapters/devices in Section 14E. Figure 14D-4 shows the 5-mL syringe and 5-mL needleless syringe. (See also Chapter 13.)

The **tuberculin syringe** is a 1-mL slender syringe with markings in tenths (0.1) and hundredths (0.01). It is also marked in minims (Figure 14D-5). This syringe is used when the amount of drug solution to be administered is less than 1 mL and for pediatric and heparin dosages. The tuberculin

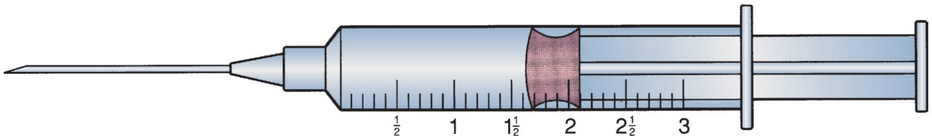

FIGURE 14D–3 A 3-mL syringe. (From Kee JL, Marshall SM: *Clinical calculations,* ed. 7, St. Louis, 2013, Elsevier.)

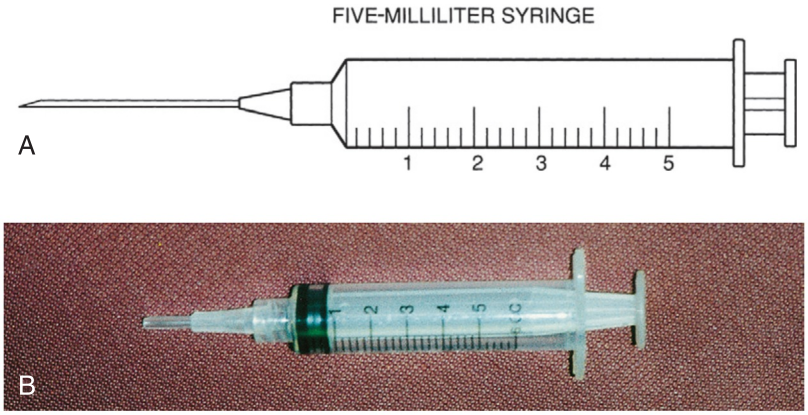

FIGURE 14D–4 5-mL syringes: **A,** 5-mL syringe with 0.2-mL markings. **B,** Needleless 5-mL BD syringe that can penetrate a rubber-top vial.

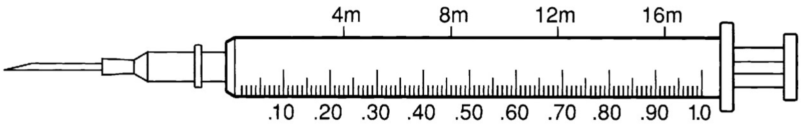

FIGURE 14D–5 Tuberculin syringe. (From Kee JL, Marshall SM: *Clinical calculations,* ed. 7, St. Louis, 2013, Elsevier.)

syringe is also available in a 0.5-mL syringe. Figure 14D-6 illustrates the 0.5-mL and 1-mL tuberculin syringes.

The **insulin syringe** has the capacity of 1 mL; however, insulin is measured in units, and insulin dosage must *not* be calculated in milliliters. Insulin syringes are calibrated as 2-unit marks, and 100 units equal 1 mL (Figure 14D-7). *Insulin syringes must be used for the administration of insulin.*

Insulin syringes are available as low-dose insulin syringes. The 1-mL insulin syringe may be purchased with a permanent attached needle or a detachable needle (Figure 14D-8).

Prefilled Drug Cartridges and Syringes

Many injectable drugs are packaged in prefilled, disposable cartridges. The disposable cartridge is placed into a Tubex injector or a reusable metal or plastic holder. Usually the prefilled cartridge contains 0.1 to 0.2 mL of excess drug solution. Based on the amount of drug to be administered, the excess solution must be expelled before administration. Figure 14D-9, *A*, illustrates the Carpuject syringe; Figure 14D-9, *B*, shows the Tubex syringe. Prefilled syringes are also used in place of prefilled cartridges.

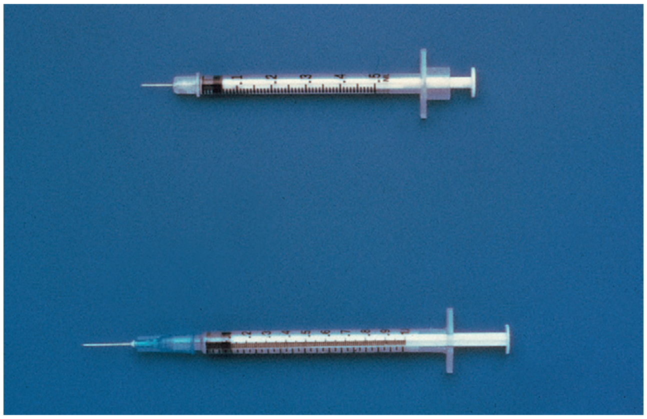

FIGURE 14D–6 Two types of tuberculin syringes. (Courtesy Becton-Dickinson Division, Franklin Lakes, New Jersey.)

Needles

Needle size has two components: **gauge** (diameter of the lumen) and length. The larger the gauge number, the smaller the diameter of the **lumen**, and the smaller the gauge, the larger the diameter of the lumen. The most common gauge numbers of needles range from 18 to 26. Needle length varies from $\frac{3}{8}$ inch to 2 inches. Table 14D-1 lists the needle gauges and lengths for use in subcutaneous and IM injections.

When choosing the needle length for an IM injection, the size of the patient and the amount of fatty tissue must be considered. A patient with minimal fatty (subQ) tissue may need a needle length of 1 inch. For a patient with more fatty tissue, the needle length for an IM injection would be 1½ to 2 inches.

Many insulin syringes and prefilled cartridges have permanently attached needles. With other syringes, the needle can be changed to the desired needle size. Needle gauge and length are indicated on the syringe package or on the top cover of the syringe. It appears as gauge/length; for example, 20 g/1½.

Figure 14D-10 illustrates the parts of a needle.

Angles for Injections

For injections, the needle enters the skin at different angles. Intradermal injections are given at a 10- to 15-degree angle,

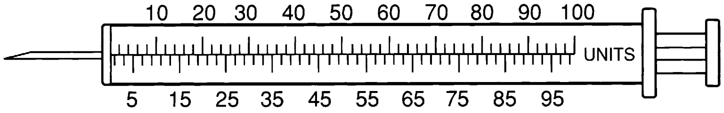

FIGURE 14D–7 Insulin syringe. (From Kee JL, Marshall SM: *Clinical calculations,* ed. 7, St. Louis, 2013, Elsevier.)

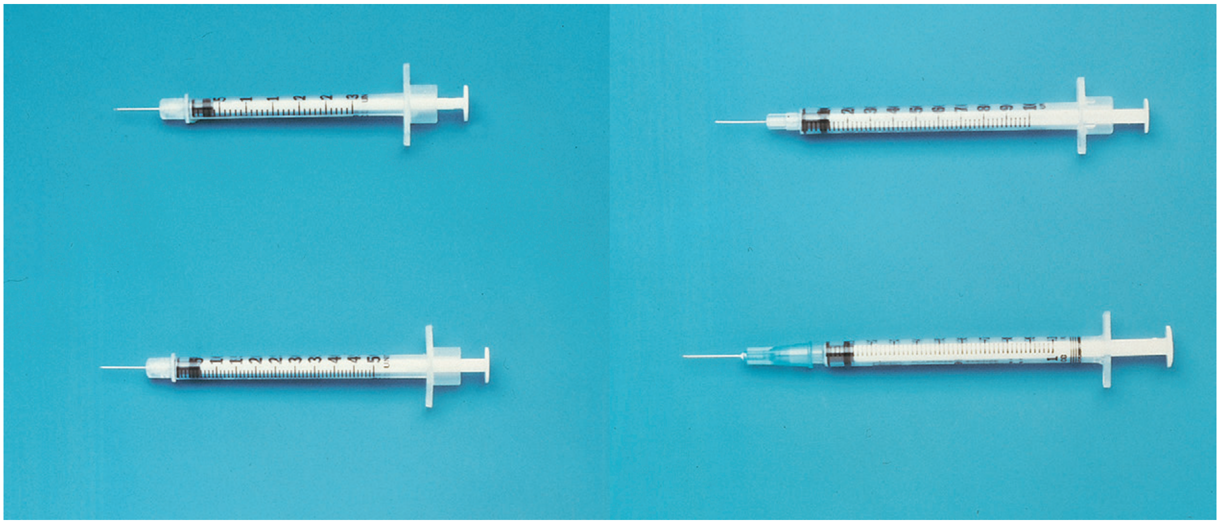

FIGURE 14D–8 Various types of insulin syringes. (Courtesy Becton-Dickinson Division, Franklin Lakes, New Jersey.)

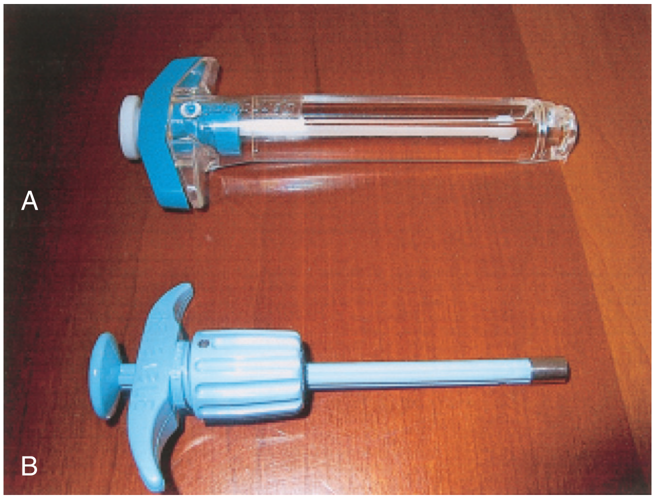

FIGURE 14D–9 **A,** Carpuject syringe. **B,** Tubex syringe.

TABLE 14D-1 NEEDLE SIZE AND LENGTH

TYPE OF INJECTION	NEEDLE GAUGE	NEEDLE LENGTHS (INCHES)
Intradermal	25, 26	⅜, ½, ⅝
Subcutaneous	23, 25, 26	⅜, ½, ⅝
Intramuscular	19, 20, 21, 22	1, 1½, 2

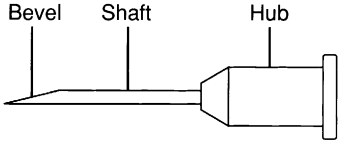

FIGURE 14D–10 Parts of a needle.

subQ injections at a 45- to 90-degree angle, and IM injections at a 90-degree angle. In Chapter 13, the angles for intradermal, subQ, and IM injections are illustrated.

PRACTICE PROBLEM 1

Syringes and Needles

Think through and answer each question. Correct answers are given at the end of the section.

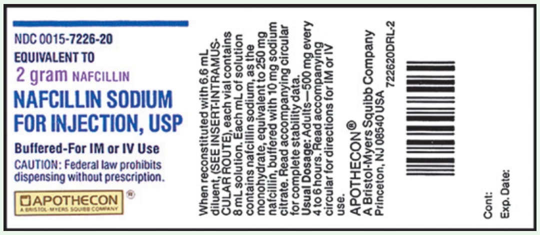
1. To mix 4 mL of bacteriostatic water in a vial with a powdered drug, which size syringe should be used?
2. To give 0.4 mL of drug solution subQ, what type of syringe should be used?
3. Meperidine (Demerol) is available in a prefilled cartridge. Half of the drug solution is used. Should the remaining solution in the cartridge be saved for future use?
4. Which has a larger needle lumen, a 21-gauge needle or a 26-gauge needle?
5. Which needle has a length of ⅝ inch, a 21-gauge needle or a 25-gauge needle?
6. Which needle is used for an IM injection, a 20-gauge needle with a 1½-inch length or a 25-gauge needle with a ⅝-inch length?

INTERPRETING INJECTABLE DRUG LABELS

Drugs for injections are stored in liquid and powder form in vials and ampules. If the drug is in liquid form, the drug dose with its equivalent in milliliters is printed on the drug label. However, drugs in powder form must be reconstituted (i.e., changed to liquid form before use). Usually the instructions for reconstitution are given on the drug label and drug instructions. If this is not the case, consult a pharmacist or the drug circular.

EXAMPLE

Nafcillin sodium is the generic name; there is no brand (trade) name. The drug is for IM or IV administration. Instructions on the drug label read: "When reconstituted with 6.6 mL of diluent, each vial contains 8 mL of solution."



NDC 0015-7226-20
EQUIVALENT TO
2 gram NAFCILLIN
NAFCILLIN SODIUM
FOR INJECTION, USP
Buffered-For IM or IV Use
CAUTION: Federal law prohibits dispensing without prescription.
APOTHECON®
A BRISTOL-MYERS SQUIBB COMPANY

When reconstituted with 6.6 mL diluent, (SEE INSERT-INTRAMUSCULAR ROUTE), each vial contains 8 mL solution. Each mL of solution contains nafcillin sodium, as the monohydrate, equivalent to 250 mg nafcillin, buffered with 10 mg sodium citrate. Read accompanying circular for complete stability data.
Usual Dosage: Adults—500 mg every 4 to 6 hours. Read accompanying circular for directions for IM or IV use.

Exp. Date:

INTRADERMAL INJECTIONS

An **intradermal** injection is usually used for skin testing to diagnose the cause of an allergy or to determine the presence of a microorganism. The choice of syringe for intradermal testing is the tuberculin syringe with a 25-gauge needle.

The inner portion of the forearm is frequently used for diagnostic testing because there is less hair in the area and the test results are more visible. The upper back may also be used as a testing site. The needle is inserted with the **bevel** pointing upward at a 10- to 15-degree angle. Do *not* aspirate. Test results are read 48 to 72 hours after the intradermal injection. A reddened or raised area is a positive reaction.

SUBCUTANEOUS INJECTIONS

Drugs injected into the **subcutaneous** (**subQ**) or fatty tissue are absorbed slowly because there are fewer blood vessels in fatty tissue. The amount of drug solution administered subQ is generally 0.5 to 1 mL at a 45-, 60-, or 90-degree angle. Drug solutions that irritate fatty tissues are given IM because they can cause sloughing of the subQ tissue.

The two types of syringes used for subQ injections are the tuberculin syringe (1 mL), calibrated in 0.1 mL and 0.01 mL, and the 3-mL syringe, calibrated in 0.1 mL. The needle gauge commonly used is 25 or 26, and the length is ⅜ to ⅝ inch. Insulin is also administered subQ and is discussed later in this section.

Calculations: Subcutaneous Injections

To calculate dosages for subQ injections, use the basic formula of *D*/*H* × *V*, the ratio-and-proportion method, fractional equation, or dimensional analysis (see Section 14B). Heparin is a drug frequently administered subQ. It can be given at a 60- to 90-degree angle, depending on the amount of fatty tissue. The skin is lifted, and the heparin solution is injected into the subQ tissue. Do not aspirate or massage the injected site, because massage could cause small-vessel damage and bleeding.

Units should be written out as a word and not abbreviated as "U" only. When U is written, it may appear as O, and thus the patient could receive a higher dose of the drug.

EXAMPLE

Order: heparin 2500 units subQ
Available: heparin 10,000 units/mL in multiple-dose vial (10 mL)
Basic Formula:

$$\frac{\text{D}}{\text{H}}\times \text{V}=\frac{25\cancel{00}\text{ units}}{10{,}0\cancel{00}\text{ units}}\times 1\text{ mL}=\frac{25}{100}=0.25\text{ mL}$$

Ratio-and-Proportion Method:

$$\begin{array}{ccccccc} H & : & V & :: & D & : & x \\ 10{,}000\text{ units} & : & 1\text{ mL} & :: & 2500\text{ units} & : & x\text{ mL} \end{array}$$

$$10{,}000\,x = 2500$$

$$x=\frac{25}{100}=0.25\text{ mL}$$

Fractional Equation:

$$\frac{\text{H}}{\text{V}}=\frac{\text{D}}{x}=\frac{10{,}000\text{ units}}{1\text{ mL}}=\frac{2500\text{ units}}{x\text{ mL}}$$

$$10{,}000x = 2500$$

$$\text{(cross-multiply)}\qquad x = 0.25\text{ mL}$$

Answer: heparin 2500 units = 0.25 mL

Dimensional Analysis:

$$\text{mL}=\frac{1\text{ ml}\times\overset{1}{\cancel{2500\text{ units}}}}{\underset{4}{\cancel{10{,}000\text{ units}}}\times 1}=\frac{1}{4}\text{ or }0.25\text{ mL}$$

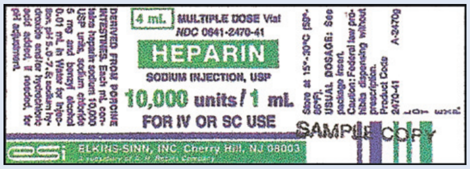
PRACTICE PROBLEM 2

Subcutaneous Injections

Use the formula chosen for the calculation of drug dosages from Section 14B. The same formula should be used when calculating oral, subQ, IM, insulin, and IV dosages.

EXAMPLE

1. Order: heparin 7500 units subQ
   Available:



4 mL
MULTIPLE DOSE Vial
NDC 0641-2470-41
HEPARIN
SODIUM INJECTION, USP
10,000 units/1 mL
FOR IV OR SC USE
DERIVED FROM PORCINE INTESTINES. Each mL contains heparin sodium 10,000 USP units, sodium chloride 5 mg and benzyl alcohol 0.01 mL in Water for Injection. pH 5.0-7.5; sodium hydroxide and/or hydrochloric acid added, if needed, for pH adjustment.
Store at 15°-30°C (59°-86°F).

INSULIN INJECTIONS

Insulin has been available since 1925, when it was extracted from beef and pork pancreases. In the 1980s, human insulin was synthetically produced and began replacing beef and pork insulin in the United States. Some individuals are allergic to beef insulin, so it has not been available since 1998. Pork insulin was more frequently prescribed because it has biologic properties similar to those of human insulin. Since December 2005, pork insulin has not been available in the United States. Some patients may be importing it. Now, insulin analogs have been developed and are currently in use.

Insulin is prescribed and measured in United States Pharmacopeia (USP) units. Most insulins are produced in concentrations of 100 units/mL. Insulin should be administered with an insulin syringe, which is calibrated to correspond with the 100 units of insulin. Insulin bottles and syringes are color-coded to avoid error. The 100 units/mL (or U-100) insulin bottle and the 100 units/mL syringe are coded orange. Administering insulin with a tuberculin syringe *should be avoided.*

Administration of medication requires attention to detail, and insulin is no exception. Insulin is ordered in units. For example, if the prescribed insulin dosage is 30 units, withdraw 30 units from a bottle of 100 units of insulin using a 100-unit calibrated insulin syringe (Figure 14D-11).

Insulin is administered subQ at a 45-, 60-, or 90-degree angle into the subQ tissue. The subQ absorption rate of insulin is slower because there are fewer blood vessels in the fatty tissue than in muscular tissue. The angle for administering insulin depends on the amount of fatty tissue. For an obese person, the angle may be 90 degrees; for a very thin person, the angle may be 45 to 60 degrees.

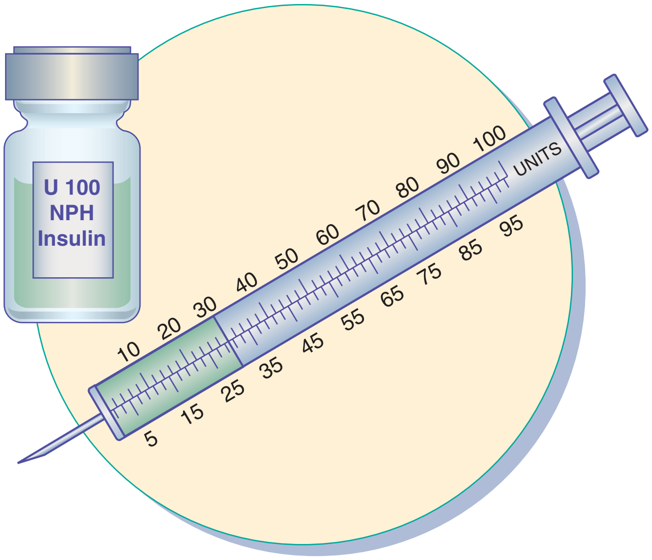

FIGURE 14D–11 Bottle of U 100 insulin and a U 100 calibrated insulin syringe. (From Kee JL, Marshall SM: *Clinical calculations,* ed. 7, St. Louis, 2013, Elsevier.)

Types of Insulins

Insulins are clear (regular or crystalline insulin) and cloudy (NPH) because of the substance protamine, which is used to prolong the action of insulin in the body. Only clear (regular) insulin can be given IV as well as subQ. The source of insulin is human (Humulin).

Insulin is categorized as rapid-acting, fast-acting, intermediate- acting, long-acting, and commercial premixed insulin (see Figure 14D-12). The first rapid-acting insulin, Humalog (lispro insulin), was approved for use in 1996. Lispro and the new rapid-acting insulins, Aspart and Apidra, act faster than regular insulin and thus can be administered 5 to 15 minutes before mealtime, whereas regular insulin is given 30 minutes before meals. Rapid-acting insulins can become effective within 5 to 15 minutes of injection and last 3 to 5 hours. Lispro insulin (Humalog) is formed by reversing two amino acids in human regular insulin (Humulin R). Aspart insulin (NovoLog) is an analog of human insulin with a rapid onset. It is structured identically to human insulin except for one amino acid. Apidra (glulisine insulin), like Aspart insulin, is a synthetic analog of natural human insulin. **Rapid-acting (Humalog, Aspart, Apidra) and fast-acting (Humulin R) regular insulin can be given both intravenously and subcutaneously. Intermediate-acting and long-acting insulins can *only* be administered subcutaneously.**

Fast-acting insulin (regular or Humulin R insulin) is also clear but takes longer to start working compared with rapid-acting insulins. It is administered 15 to 30 minutes before meals and is effective for 6 to 8 hours. It is usually given before the meal, but it is sometimes given during or after the meal. Humulin R and Novolin R are brand names for fast-acting human insulin.

Intermediate-acting insulin (NPH, Humulin N, Novolin N) is administered 30 minutes before the meal (breakfast) and becomes effective in 1 to 2 hours. Its duration of action in the body is 12 to 18 hours. This type of insulin contains protamine, which prolongs the action in the body. It is cloudy because of the protamine added to the regular insulin. It can *only* be given subcutaneously. Humulin N can be mixed with Humulin R (regular insulin) or rapid-acting insulin in the same syringe.

The long-acting insulins are insulin determir (Levemir), an analog of human insulin, and insulin glargine (Lantus). Lantus is the first long-acting recombinant DNA (rDNA) human insulin for patients with type 1 or 2 diabetes mellitus. Lantus and Levemir are clear, colorless insulins that are to be given *only* subcutaneously and *not* intravenously. **Lantus and Levemir *cannot* be mixed with other insulins or given intravenously.** The long-acting insulin acts within 1 to 2 hours and lasts in the body for 18 to 24 hours. The Levemir vial is tall and has a green top. The Lantus vial is taller and narrower than the other types of insulin. It has a purple top and purple print on the label. Levemir is usually administered in the evening or at bedtime; however, it can be administered once or twice a day subcutaneously. Lantus is usually administered at bedtime, and the incidence of nocturnal hypoglycemia is not common. Some patients report more pain at the injection site with long-acting insulins than with Humulin N or NPH insulin.

The use of commercially premixed combination insulins has become popular for patients with diabetes who mix fast-acting and intermediate-acting insulins. Examples are two groups: the rapid-acting and intermediate-acting insulins are Novolog mix 70/30 and Humalog mix 75/25. The fast-acting and intermediate-acting insulins are Humulin 70/30, Novolin 70/30, and Humulin 50/50 (see Figure 14D-12). They are available in vials or pens that resemble a fountain pen (Figures 14D-12 and 14D-13). Some patients need less than 30 units of Humulin R and more Humulin N, so these combinations of insulins cannot be used. They must mix their insulins according to the prescribed units of insulin.

Mixing Insulins

Regular insulin is frequently mixed with insulin containing protamine (NPH, Humulin N). The following is an example of a method for mixing insulin. Remember that Lantus and Levemir insulins cannot be mixed with regular insulin.

EXAMPLE

Order: regular insulin 10 units and Humulin N insulin 35 units subQ every day at 7:00 AM

Available: regular insulin 100 units/mL and Humulin N insulin 100 units/mL. Insulin syringe: 100 units/mL

METHOD

1. Clean the rubber tops of the insulin bottles.
2. Draw up 35 units of air, and inject into the Humulin N insulin bottle. Avoid letting the needle contact the Humulin N insulin solution. Withdraw the needle.
3. Draw up 10 units of air, and inject into the regular insulin bottle.
4. First, withdraw 10 units of regular insulin. Regular insulin is always drawn up first.
5. Insert needle into Humulin N bottle, and withdraw 35 units of Humulin N insulin. The total is 45 units.
6. Administer the two insulins immediately after mixing. Do *not* allow the insulin mixture to stand, because unpredicted physical changes may occur.

Insulin pumps are discussed in Chapter 52.

INTRAMUSCULAR INJECTIONS

Muscle has more blood vessels than fatty tissue, so medications given by **intramuscular (IM)** injection are absorbed more rapidly than those given by subQ injection. The volume of solution for an IM injection is 0.5 to 3 mL, with the average being 1 to 2 mL. A volume of drug solution greater than 3 mL causes increased muscle tissue displacement and possible tissue damage. Occasionally 5 mL of selected drugs, such as magnesium sulfate, may be injected into a large muscle, such as the dorsogluteal. A dose greater than 3 mL is usually divided and given at two different sites.

The needle gauges for IM injections are 19 and 20 for thick solutions and 20 and 21 for thin solutions. IM injections are administered at a 90-degree angle. The needle length depends on the amount of adipose (fat) and muscle tissue; the average needle length is 1½ inches.

The discussion on IM injections is divided into three subsections: (1) drug solutions for injection, (2) powdered drug

reconstitution, and (3) mixing injectable drugs. An example is given for each subsection, and practice problems follow.

Sites of IM injections are shown in Chapter 13.

Drug Solutions for Injection

Commercially premixed drug solutions are stored in vials and ampules for ready use. The drug label on the container gives the drug dose by weight and its equivalent in milliliters.

Powdered Drug Reconstitution

Certain drugs lose their potency in liquid form; therefore manufacturers package these drugs in powdered form. They are reconstituted using a **diluent** (bacteriostatic water or saline) before administration. The drug label or the instructional insert (accompanying pamphlet) frequently gives the type and amount of diluent to use. If the type and amount

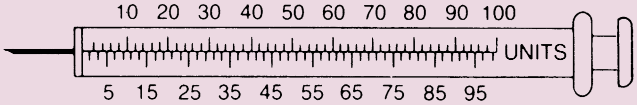
PRACTICE PROBLEM 3

Insulins

Indicate on the insulin syringe the amount of insulin that should be withdrawn for each type of insulin.

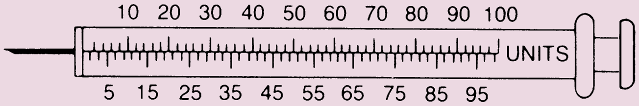
1. Order: NPH insulin 45 units subQ

   Available: NPH insulin 100 units/mL and insulin syringe 100 units/mL



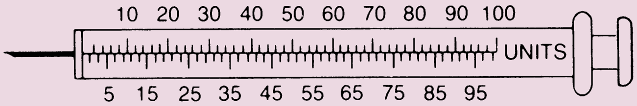
2. Order: regular insulin 15 units and Humulin N insulin 25 units subQ

   Available: regular insulin 100 units/mL and Humulin N insulin 100 units/mL, and insulin syringe 100 units/mL



3. Order: regular insulin 6 units and Humulin N insulin 40 units

   Available: regular insulin 100 units/mL and Humlin N insulin 100 units/mL, and insulin syringe 100 units/mL



of diluent are not on the drug label or in the instructional insert, contact the pharmacist.

EXAMPLE

Order: gentamicin (Garamycin) 50 mg IM

Available: gentamicin 80 mg/2 mL in a vial

a. BF: $\frac{D}{H} \times V = \frac{50}{80} \times 2 = \frac{100}{80} = 1.25\text{ mL}$

b. RP: $H : V :: D : x$

$$80\text{ mg} : 2\text{ mL} :: 50\text{ mg} : x\text{ mL}$$

$$80\,x = 100$$

$$x = \frac{100}{80} = 1.25\text{ mL}$$

c. FE: $\frac{H}{V} = \frac{D}{x} \quad \frac{80\text{ mg}}{2\text{ mL}} = \frac{50\text{ mg}}{x}$

$$80x = 100$$

$$(\text{cross-multiply})\ x = 1.25\text{ mL}$$

d. DA: $\text{mL} = \frac{2\text{ mL} \times 50\,\cancel{\text{mg}}}{80\,\cancel{\text{mg}} \times 1} = \frac{100}{80} = 1.25\text{ mL}$

Usually manufacturers determine the amount of diluent to mix with the drug powder to yield 1 to 2 mL/dose. The powdered drug occupies space; therefore the volume of the drug solution is increased. Once the powdered drug has been reconstituted, the unused drug solution should be dated and initialed on the drug label. Unused drug solutions in vials are refrigerated and may be used for 48 hours to 1 week according to the manufacturer's recommendation. Unused drug solutions in ampules are discarded.

Mixing Injectable Drugs

Drugs mixed together in the same syringe must be compatible to prevent precipitation. To determine drug compatibility, check drug reference texts or with a pharmacist. When in doubt about compatibility, do *not* mix drugs.

The three methods used for mixing drugs are (1) mixing two drugs in the same syringe from two vials, (2) mixing two drugs in the same syringe from one vial and one ampule, and (3) mixing two drugs in a prefilled cartridge from a vial.

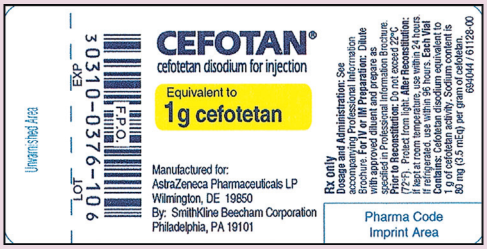
Method 1: Mixing Two Drugs in the Same Syringe from Two Vials

1. Draw air into the syringe to equal the amount of solution to be withdrawn from the first vial, and inject the air into the first vial. Do not allow the needle to come into contact with the solution. Remove the needle.

EXAMPLE

Order: cefotetan disodium (Cefotan) 0.5 g IM, q12h

Available (NOTE: Circular states to add 2.6 mL of diluent to yield 3 mL of drug.):



Unvarnished Area

EXP

LOT

3 0310-0376-10 6

F.P.O.

CEFOTAN®

cefotetan disodium for injection

Equivalent to

1g cefotetan

Manufactured for:
AstraZeneca Pharmaceuticals LP
Wilmington, DE 19850
By: SmithKline Beecham Corporation
Philadelphia, PA 19101

Rx only

Dosage and Administration: See accompanying Professional Information Brochure. **For IV or IM Preparation:** Dilute with approved diluent and prepare as specified in Professional Information Brochure. **Prior to Reconstitution:** Do not exceed 22°C (72°F). Protect from light. **After Reconstitution:** If kept at room temperature, use within 24 hours. If refrigerated, use within 96 hours. **Each Vial Contains:** Cefotetan disodium equivalent to 1 g of cefotetan activity. Sodium content is 80 mg (3.5 mEq) per gram of cefotetan.

694044 / 61128-00

Pharma Code Imprint Area

Add 2.6 mL of diluent; 1 g of cefotetan disodium = 3 mL

$$\text{BF: } \frac{D}{H} \times V = \frac{0.5}{1} \times 3\text{ mL} = 1.5\text{ mL}$$

$$= 0.5\text{ g of cefotetan disodium}$$

$$\text{DA: mL} = \frac{3\text{ mL} \times 0.5\,\cancel{\text{g}}}{1\,\cancel{\text{g}} \times 1} = 1.5\text{ mL}$$

No conversion is needed.

2. Draw air into the syringe to equal the amount of solution to be withdrawn from the second vial. Invert the second vial, and inject the air. Withdraw the desired amount of solution from the second vial.
3. Change the needle, unless the entire volume in the first vial will be used.
4. Invert the first vial, and withdraw the desired amount of solution.

Method 2: Mixing Two Drugs in the Same Syringe from One Vial and One Ampule

1. Inject air into the vial.
2. Remove the desired amount of solution from the vial.
3. Withdraw the desired amount of solution from the ampule.

Method 3: Mixing Two Drugs in a Prefilled Cartridge from a Vial

1. Check the drug dose and the amount of solution in the prefilled cartridge. If a smaller dose is needed, or if a prefilled drug syringe is used, expel the excess solution.
2. Draw air into the cartridge to equal the amount of solution to be withdrawn from the vial. Invert the vial, and inject the air.
3. Withdraw the desired amount of solution from the vial. Be sure that the needle remains in the fluid, and do not take more solution than needed.

Mixing Drugs in the Same Syringe

Order: meperidine (Demerol) 25 mg and atropine sulfate 0.4 mg IM

Available: meperidine in a Tubex cartridge labeled 50 mg/mL

Atropine sulfate in a multidose vial labeled 0.4 mg/mL

How many milliliters of each drug should be given, and how are they mixed? ______

1. Meperidine dose
   a. $\frac{D}{H} \times V = \frac{25}{50} \times 1 = \frac{25}{50} = 0.5\text{ mL}$
   b. $H \quad : \quad V \quad :: \quad D \quad : \quad x$

$$50\text{ mg} : 1\text{ mL} :: 25\text{ mg} : x\text{ mL}$$

$$50\,x = 25$$

$$x = \frac{1}{2} = 0.5\text{ mL}$$

2. Atropine dose:
   The label indicates 0.4 mg = 1 mL.
   Answer: Give meperidine 0.5 mL and atropine 1 mL.

Procedure

Mix two drugs in the cartridge, with one drug from a vial and the other drug in the prefilled cartridge.

1. Check the drug dose and volume on the prefilled cartridge.
2. Expel 0.5 mL and any excess drug solution (meperidine) from the cartridge (0.5 mL remains in the cartridge). Have another nurse witness the waste of a narcotic.
3. Draw 1 mL of air into the cartridge, and inject the air into the vial that contains the atropine.
4. Withdraw 1 mL of atropine from the vial into the meperidine solution in the cartridge.

PRACTICE PROBLEM 4

Intramuscular Injections

1. Order: cefazolin (Ancef) 500 mg IM, q6h

Sterile
For IM or IV Use
Pfizer Roerig
Division of Pfizer Inc, NY, NY 10017

DOSAGE AND USE
See accompanying prescribing information.
RECOMMENDED STORAGE
Before Reconstitution: Store at or below 25°C (77°F) and protect from light.
FOR IM USE: See "Preparation For Intramuscular Injection" in the RECONSTITUTION section of package insert.
FOR IV USE: First reconstitute with approximately 5 mL of a diluent cited in the package insert. Withdraw the entire contents of the vial and further dilute with a recommended diluent.
For Intermittent Infusion: Dilute in 20 to 40 mL of diluent per gram and administer over a 15-30 minute time period.
For Continuous Infusion: Dilute to a final cefoperazone concentration range of 2 to 25 mg/mL.
After Reconstitution: Solutions may be stored for 24 hours at room temperature and under normal lighting conditions. See package insert for refrigerator and freezer storage. Discard solutions stored beyond recommended periods.

c. Explain how the two drugs would be mixed.

ANSWERS TO PRACTICE PROBLEMS

1 SYRINGES AND NEEDLES

1. 5-mL syringe
2. Tuberculin syringe (1 mL)
3. No, it should be discarded in the sink or toilet and witnessed by another RN or LPN, according to agency policy.
4. 21-gauge needle
5. 25-gauge needle
6. 20-gauge needle 1.5 ($1\frac{1}{2}$) inches in length

2 SUBCUTANEOUS INJECTIONS

1. 0.75 mL
2. Lovenox 0.2 mL for 20 mg
3. The drug label reads: 1.25 mL = 0.5 mg of atropine. Also, under the word “atropine,” it reads 0.4 mg/mL

   a. BF: $\frac{D}{H} \times V = \frac{0.5}{0.4} \times 1 = 1.25\,\text{mL}$

   b. RP: $H : V :: D : x$

   $0.4\,\text{mg} : 1\,\text{mL} :: 0.5\,\text{mg} : x\,\text{mL}$

   $0.4x = 0.5$

   $x = \frac{0.5}{0.4} = 1.25\,\text{mL}$

   c. DA: $\text{mL} = \frac{1\,\text{mL} \times 0.5\,\cancel{\text{mg}}}{0.4\,\cancel{\text{mg}} \times 1} = 1.25\,\text{mL}$

4. A tuberculin syringe should be used.

   a. BF: $\frac{D}{H} \times V = \frac{0.2}{1.0} \times 1 = 1.0\overset{2.0}{\overline{\big)0.20}} = 0.2\,\text{mL}$

   b. RP: $H : V :: D : x$

   $1\,\text{mg} : 1\,\text{mL} :: 0.2\,\text{mg} : x\,\text{mL}$

   $1.0x = 0.2$

   $x = \frac{0.2}{1.0} = 0.2\,\text{mL}$

   Answer: epinepherine 0.2 mg = 0.2 mL

4 INTRAMUSCULAR INJECTIONS USING BASIC FORMULA, RATIO AND PROPORTION, FRACTIONAL EQUATION, OR DIMENSIONAL ANALYSIS

1. Instructions on the drug label read: Add 2.5 mL of sterile water. The drug solution equals 3.0 mL (drug powder is equal to 0.5 mL).

   Change 1 g to mg; 1 g = 1000 mg

   or Change 500 mg to g; 500 mg = 0.500 g (0.5 g)

   a. $\text{BF: } \frac{D}{H} \times V = \frac{0.5}{1\,g} \times 3\,mL = 1.5\,mL$

   b. $\text{RP: } H : V :: D : x$

   $1000\,mg : 3\,mL :: 500\,mg : x\,mL$

   $1000x = 1500$

   $x = 1.5\,mL$

   c. $\text{DA: } mL = \frac{3\,mL \times 1\,\cancel{g} \times \overset{1}{\cancel{500}}\,\cancel{mg}}{1\,\cancel{g} \times \underset{2}{\cancel{1000}}\,\cancel{mg} \times 1} = \frac{3}{2}$

   $= 1.5\,mL$

   Answer: cefazolin 500 mg = 1.5 mL

2. The atropine drug label is marked as 0.4 mg/mL. The approximate equivalent of 0.3 mg is 0.8 mL. If the 0.3 mg = 0.8 mL is unknown, the problem may be calculated using 0.4 mg = 1 mL

   $$\text{BF: } \frac{D}{H} \times V = \frac{0.3}{0.4} \times 1 = \frac{0.3}{0.4} = 0.75, \text{ or } 0.8\,mL$$

3. For oxacillin sodium, the drug label indicates that 2.7 mL of sterile water should be added to the vial containing 500 mg of drug. The total volume would be 3 mL.

   a. $\text{BF: } \frac{D}{H} \times V = \frac{250}{500} \times 3.0 = \frac{750}{500} = 1.5\,mL$

   b. $\text{FE: } \frac{H}{V} = \frac{D}{x}\ \frac{500\,mg}{3\,mL} = \frac{250\,mg}{x\,mL}$

   (cross-multiply) $500x = 750$

   $x = 1.5\,mL$

   c. $\text{DA: } mL = \frac{3\,mL \times \overset{1}{\cancel{250}}\,\cancel{mg}}{\underset{2}{\cancel{500}}\,\cancel{mg} \times 1} = 1.5\,mL$

4. $\text{BF: } \frac{D}{H} \times V = \frac{0.25}{0.50} \times 2 \times \frac{0.50}{0.50} = 1\,mL$

   Withdraw 1 mL from the ampule. Discard the remaining 1 mL of digoxin solution.

5. Thorazine 50 mg = 2 mL. Yes, the vial can be used for multiple doses.

6. Meperidine 60 mg = 0.6 mL; hydroxyzine 25 mg = 0.5 mL

   Meperidine

   $$\text{BF: } \frac{D}{H} \times V = \frac{60}{100} \times 1 \times \frac{60}{100} = 0.6\,mL$$

Hydroxyzine

$$\text{BF: } \frac{D}{H} \times V = \frac{25}{100} \times 2 \times \frac{50}{100} = 0.5\text{ mL}$$

Procedure

a. Withdraw 0.5 mL of hydroxyzine from the vial.

b. Meperidine is in a dosette ampule. Withdraw 0.6 mL of meperidine solution into the syringe containing hydroxyzine. Discard the balance of the solution in the ampule.

c. Total amount of the two drug solutions is 1.1 mL. Administer IM.

7. a. Morphine vials 8 mg/mL and 10 mg/mL. Morphine 5 mg/mL vial could not be used because it is a single-vial dose.

b. Morphine 8 mg/mL vial

$$\text{BF: } \frac{D}{H} \times V = \frac{6\ \cancel{mg}}{8\ \cancel{mg}} \times 1\text{ mL} = \frac{6}{8} = 0.75\text{ mL}$$

Morphine 10 mg/mL vial

$$\text{BF: } \frac{D}{H} \times V = \frac{6\ \cancel{mg}}{10\ \cancel{mg}} \times 1\text{ mL} = \frac{6}{10} = 0.6\text{ mL}$$

8. a. 1 g = 1000 mg

b. 750 mg × 2 (b.i.d.) = 1500 mg/day or 1.5 g/day

c. $$\frac{D}{H} \times V = \frac{\overset{3}{\cancel{750}}}{\underset{4}{\cancel{1000}}} \times 3.4\text{ mL} = \frac{3 \times 3.4}{4} = \frac{10.2}{4} = 2.55 \text{ or } 2.6\text{ mL of Claforan}$$

9. a. Either the ampule or the vial could be used. The diazepam 5 mg/mL is a multiple-dose vial that contains 10 mL of drug solution. The 10 mg/2 mL ampule is to be used one time; if not entirely used, it must be discarded.

$$\text{Vial: BF: } \frac{D}{H} \times V = \frac{6\ \cancel{mg}}{5\ \cancel{mg}} \times 1\text{ mL} = 1.2\text{ mL}$$

b. ***or***

$$\begin{aligned} &\text{Ampule: RP: H} : \text{V} :: \text{D} : x \\ &10\text{ mg} : 2\text{ mL} :: 6\text{ mg} : x\text{ mL} \\ &10x = 12 \\ &x = 1.2\text{ mL} \end{aligned}$$

$$\text{Vial: DA: mL} = \frac{1\text{ mL} \times 6\ \cancel{mg}}{5\ \cancel{mg} \times 1} = \frac{6}{5} = 1.2\text{ mL}$$

$$\text{Ampule: FE: } \frac{H}{V} = \frac{D}{x} = \frac{10\text{ mg}}{2\text{ mL}} = \frac{6\text{ mg}}{x}$$

$$\begin{aligned} &\text{(cross-multiply) } 10x = 12 \\ &x = 1.2\text{ mL} \end{aligned}$$

10. a. $$\begin{aligned} &\text{RP: H} : \text{V} :: \text{D} : \text{X} \\ &100\text{ mcg} : 1\text{ mL} :: \overset{3}{\cancel{60}}\text{ mcg} : \text{X} \\ &\underset{5}{\cancel{100}}\ \text{X} = 60 \\ &\text{X} = 0.6\text{ mL of cyanocobalamin} \end{aligned}$$

$$\text{DA: mL} = \frac{1 \qquad \times 60\text{ mcg}}{100\text{ mcg} \times 1} = \frac{3}{5} = 0.6\text{ mL of cyanocobalamin}$$

11. 1 mL per dose

$$\text{DA: mL} = \frac{2\text{ mL} \times 1\ \cancel{g} \qquad \times \overset{1}{\cancel{500}}\ \cancel{mg}}{1\ \cancel{g} \quad \times \underset{2}{\cancel{1000}}\ \cancel{mg} \times 1} = \frac{2}{2} = 1\text{ mL}$$

12. a. meperidine:

$$\text{DA: mL} = \frac{1\text{ mL} \quad \times \overset{7}{\cancel{35}}\ \cancel{mg}}{\underset{10}{\cancel{50}}\ \cancel{mg} \times 1} = \frac{7}{10} = 0.7\text{ mL}$$

b. promethazine

$$\text{DA: mL} = \frac{1\text{ mL} \quad \times \overset{2}{\cancel{10}}\ \cancel{mg}}{\underset{5}{\cancel{25}}\ \cancel{mg} \times 1} = \frac{2}{5} = 0.4\text{ mL}$$

c. Procedure:

1. Obtain 0.7 mL of meperidine from the ampule and 0.4 mL of promethazine from the ampule.
2. Discard the remaining solutions within the ampules.

Section 14E: Calculations of Intravenous Fluids

OBJECTIVES

- Describe the differences between continuous intravenous infusion and intermittent intravenous infusion.
- Define macrodrip and microdrip sets, keep vein open (KVO), and to keep open (TKO).
- Calculate intravenous flow rate using one of the given formulas.
- Explain how intravenous drug solutions administered by secondary set are calculated.
- Differentiate between volumetric and nonvolumetric intravenous regulators and pump electronic regulators.

OUTLINE

Key Terms
Continuous Intravenous Administration
  Intravenous Sets
  Calculating Intravenous Flow Rate
  Mixing Drugs for Continuous Intravenous Administration
Intermittent Intravenous Administration
  Secondary Intravenous Sets without IV Pumps
Intermittent Infusion Adapters/Devices
Direct Intravenous Injections
Electronic Intravenous Regulators
Patient-Controlled Analgesia
  Patient Teaching
Calculating Flow Rates for Intravenous Drugs

primary IV line set, p. 192
secondary IV line set, p. 192
to keep open (TKO), p. 191
volumetric regulator, p. 195

Intravenous (IV) fluid therapy is used to administer fluids that contain water, dextrose, vitamins, electrolytes, and drugs. Today an increasing number of drugs are administered by the IV route for direct absorption and fast action. Some drugs are given by IV push (**bolus**). Many drugs administered IV irritate the veins, so these drugs are diluted in 50 to 100 mL of fluid. Other drugs are delivered in a large volume of fluid over a specific period, such as 4 to 8 hours.

Two methods are used to administer IV fluids and drugs: continuous IV infusion and intermittent IV infusion. Continuous IV infusion replaces fluid loss, maintains fluid balance, and serves as a vehicle for drug administration. Intermittent IV infusion is used primarily to give IV drugs.

Nurses have an important role in the preparation and administration of IV solutions and IV drugs. The nursing functions and responsibilities during drug preparation include the following:

- Knowing IV sets and their drop factors
- Calculating IV flow rates
- Mixing and diluting drugs in IV fluids
- Gathering equipment
- Knowing the drugs and the expected and untoward reactions

Nursing responsibilities continue with assessment of the patient for effectiveness and untoward effects of the therapy and assessment of the IV site.

CONTINUOUS INTRAVENOUS ADMINISTRATION

When IV solutions are required, the health care provider orders the type and amount of IV solution in liters over a 24-hour period or in milliliters per hour. The nurse calculates the IV flow rate according to the drop factor, the amount of fluids to be administered, and the time period.

Intravenous Sets

Various IV infusion sets are marketed by Abbott, Cutter, McGaw, and Travenol. The **drop factor**, the number of drops per milliliter, is normally printed on the packaging cover of the IV set. A set that delivers large drops per milliliter (10 to 20 gtt/mL) is called a **macrodrip set,** and one that delivers small drops per milliliter (60 gtt/mL) is called a **microdrip (minidrip) set.** Examples of drop factors, macrodrip sets, and microdrip sets are listed in Table 14E-1.

TABLE 14E-1 INTRAVENOUS SETS

MANUFACTURER	DROPS (gtt/mL)
Macrodrip Sets	
Abbott	15
Cutter	20
McGaw	15
Travenol	10
Microdrip Sets	
Travenol	60
Minidrip sets	60

In most instances, the nurse has the choice of using either the macrodrip or microdrip set. If the IV rate is to infuse at 100 mL/h or more, the macrodrip set is usually used. If the infusion rate is less than (<) 100 mL/h or the patient is a child, the microdrip set is preferred. Slow drip rates of <100 mL/h make macrodrip adjustment difficult.

At times, IV fluids are given at a slow rate to **keep vein open (KVO),** also called **to keep open (TKO)**. The reasons for ordering KVO include a suspected or potential emergency situation for rapid administration of fluids and drugs, and the need for an open line to give IV drugs at specified hours. For KVO, a microdrip set (60 gtt/mL) and a 250-mL IV bag may be used. KVO is usually regulated to deliver 10 mL/h.

Calculating Intravenous Flow Rate

Three different methods may be used to calculate IV flow rate (drops per minute, gtt/min). The nurse should select one method, memorize it, and consistently use it to calculate IV flow rate. Method II is usually the preferred method.

Method I: Three-Step

1. $\dfrac{\text{Amount of solution}}{\text{Hours to administer}} = \text{milliliters per hour (mL/h)}$
2. Milliliters per hour = milliliters per minute (mL/min)
3. Milliliters per minute × drops per milliliter of IV set = drops/minute (gtt/min)

Method II: Two-Step

1. $\dfrac{\text{Amount of fluid}}{\text{Hours to administer}} = \text{milliliters per hour (mL/h)}$
2. $\dfrac{\text{Milliliters per hour} \times \text{Drops per milliliter (IV set)}}{\text{60 minutes}}$ $= \text{drops/minute (gtt/min)}$

Method III: One-Step

1. $\dfrac{\text{Amount of fluid} \times \text{Drops per milliliter (IV set)}}{\text{Hours to administer} \times \text{Minutes per hours (60)}}$ $= \text{drops/minute (gtt/min)}$

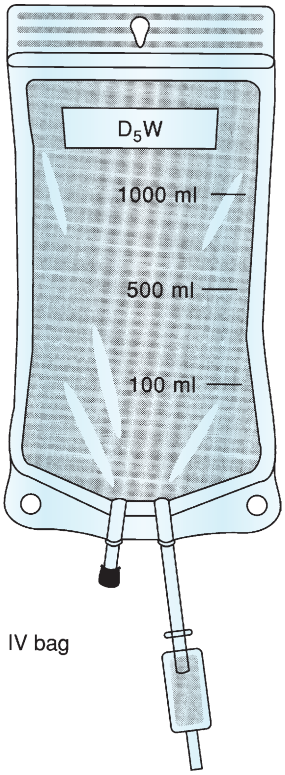

FIGURE 14E–1 Intravenous bag. (From Kee JL, Marshall SM: *Clinical calculations,* ed. 7, St. Louis, 2013, Elsevier.)

Mixing Drugs for Continuous Intravenous Administration

Drugs such as potassium chloride and vitamins are frequently added to the IV solution bag for continuous IV infusion. Drugs should be added to the bag or bottle immediately before administering the IV fluid. Inject the drug into the rubber stopper on the IV bag or bottle, and rotate the bag several times to ensure that the drug is dispersed throughout the solution (Figure 14E-1). *Do not add the drug while the infusion is running unless the bag is rotated.* A drug solution injected into an upright infusing IV solution concentrates the drug into the lower portion of the IV bag, preventing it from dispersing evenly. The patient receives a concentrated drug solution, which may be harmful, for example, if the drug is potassium chloride. If drugs are injected into the IV bag before use, the bag should be refrigerated to maintain drug potency.

Commercially prepared IV solutions contain various nutrients (e.g., dextrose) and electrolytes. The commonly used solutions are 5% dextrose in water (D_5W), normal saline (NSS), one-half normal saline (½ NSS), and lactated Ringer's (LR). Abbreviations for these types of solutions are listed in Table 14E-2.

INTERMITTENT INTRAVENOUS ADMINISTRATION

Some IV drugs are prescribed to be administered three to six times a day in a small volume of IV fluid (50 to 100 mL of

TABLE 14E-2 ABBREVIATIONS OF SOLUTIONS

INTRAVENOUS SOLUTIONS	ABBREVIATIONS
5% Dextrose in water	D_5W, 5% D/W
10% Dextrose in water	$D_{10}W$, 10% D/W
0.9% Sodium chloride, normal saline solution	0.9% NaCl, NSS
0.45% Sodium chloride, ½ normal saline solution	0.45% NaCl, ½ NSS
5% Dextrose in 0.9% sodium chloride	D_5NSS, 5% D/NSS, 5% D/0.9% NaCl
5% Dextrose in 0.45% sodium chloride or 5% Dextrose in ½ normal saline solution	D_5/½ NSS, 5% D/½ NSS
Lactated Ringer's solution	LR

D_5W or NSS 0.9% sodium chloride). The drug solution is usually infused over a period of 15 minutes to 1 hour. Separate tubing for IV drugs, the **secondary IV line set,** is inserted into a port (rubber stopper) of the IV connector on the continuous, or **primary IV line set.** This type of IV administration is called *intermittent IV therapy.*

EXAMPLE

Order: 1000 mL of 5% dextrose in water (D_5W) with potassium chloride (KCl) 20 mEq in 8 h

Available: 1000 mL of 5% dextrose in water. Potassium chloride 40 mEq/20 mL ampule. IV set labeled 10 gtt/mL

Drug calculation: Use the basic formula, the ratio-and-proportion method, fractional equation, or dimensional analysis (refer to Section 14B if needed).

a. $\text{BF: } \frac{D}{H} \times V = \frac{20}{40} \times 20 = \frac{400}{40} = 10 \text{ mL of KCl}$

b. RP:

$$\begin{array}{ccccccc} H & : & V & :: & D & : & x \\ 40\text{ mEq} & : & 20\text{ mL} & :: & 20\text{ mEq} & : & x\text{ mL} \end{array}$$

$$40x = 400$$

$$x = 10 \text{ mL of KCl}$$

c. $\text{DA: mL} = \frac{20\text{ mL} \times \overset{1}{\cancel{20}}\,\cancel{\text{mEq}}}{\underset{2}{\cancel{40}}\,\cancel{\text{mEq}} \times 1} = 10 \text{ mL of KCl}$

The calculation of IV flow rate is described using the three methods outlined previously. However, it is strongly recommended that only one method be selected to determine IV flow rate.

Method I

1. $\frac{1000\text{ mL}}{8\text{ h}} = 125 \text{ mL/h}$
2. $\frac{125\text{ mL}}{60\text{ min}} = 2.0 - 2.1 \text{mL/h}$
3. 2.1 × 10 = 21 gtt/min

Method II

1. $1000 \div 8 = 125 \text{ mL/h}$
2. $\frac{125\text{ mL/h} \times \overset{1}{\cancel{10}}\text{ gtt/mL}}{\underset{6}{\cancel{60}}\text{ min}} = \frac{125}{6} = 20 - 21 \text{gtt/min}$

Method III

1. $\frac{1000\text{ mL} \times \overset{1}{\cancel{10}}\text{ gtt/mL}}{8\text{ h} \times \underset{6}{\cancel{60}}\text{ min}} = \frac{1000}{48} = 20 \text{ or } 21 \text{gtt/min}$

PRACTICE PROBLEM 1

Continuous Intravenous Flow Rates

Select one of the three methods to calculate IV flow rate.

1. Order: 1000 mL of D_5/½ NSS to infuse over 12 h

   Available: macrodrip set with 10 gtt/mL and a microdrip set with 60 gtt/mL

   a. Should a macrodrip or microdrip IV set be used? _______

   b. Calculate the IV flow rate in drops per minute according to the IV set that was selected. _______

2. Order: 3 L of IV solutions to infuse over 24 h

   1 liter of D_5W and 2 liters of D_5/½ NSS

   a. One liter is equal to how many milliliters? _______

   b. Each liter should infuse for how many hours? _______

   c. The institution uses a set with a drop factor of 15 gtt/mL. How many drops per minute should the patient receive? _______

3. Order: 250 mL of D_5W to KVO

   a. What type of IV set should be used? ______

   b. Determine how many drops per minute the patient should receive. ______

4. Order: 1000 mL of D_5/½ NSS, 1 vial of multiple vitamin (MVI), and 10 mEq of KCl (potassium chloride) in 10 h

   Available: 1000 mL of D_5/½ NSS; MVI: 1 vial; KCl 20 mEq/20-mL vial. Macrodrip set: 15 gtt/mL; microdrip set 60 gtt/mL

   a. How many milliliters of KCl should be injected into the IV bag? ______

   b. How many drops per minute should the patient receive using the macrodrip set and the microdrip set?

Secondary Intravenous Sets without IV Pumps

Two IV sets available to administer IV drugs are (1) the calibrated cylinder (chamber) with tubing, such as the Buretrol, Volutrol, and Soluset; and (2) the secondary IV set, which is similar to a regular IV set except the tubing is shorter (Figure 14E-2). The secondary IV line set is used mostly to infuse small volumes—50, 100, 250 mL and for children's IV solution. The chamber of the Buretrol, Volutrol, and Soluset holds 150 mL of solution. Medication is injected into the chamber and then diluted with solution. These methods of administering IV drugs are referred to as **IV piggyback (IVPB).**

Drugs for IV infusion are diluted before infusion. Clinical agencies frequently have their own protocols for dilutions; the

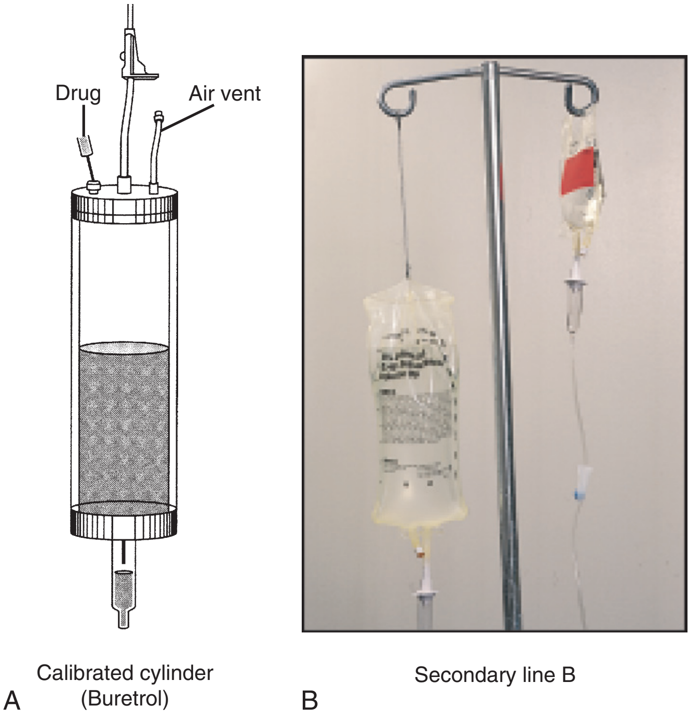

FIGURE 14E–2 **A,** The calibrated cylinder (Buretrol) is an example of a secondary intravenous (IV) device. **B,** An example of a secondary line containing medication. The primary IV bag is 6 inches below the secondary IV bag. (**A,** From Kee JL, Marshall SM: *Clinical calculations,* ed. 7, St. Louis, 2013, Elsevier. **B,** From Leahy JM, Kizilay PE: *Foundations of nursing practice: a nursing process approach,* Philadelphia, 1998, Saunders.)

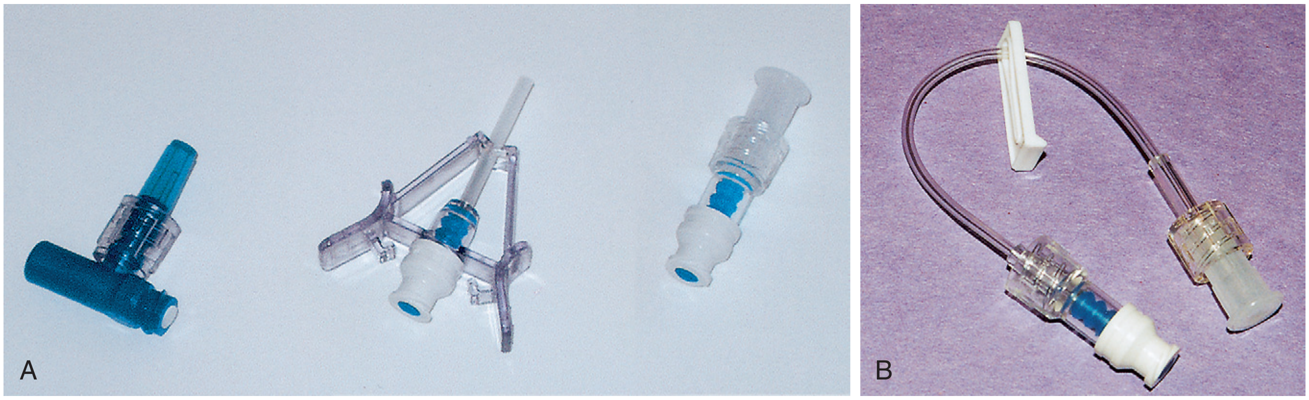

FIGURE 14E–3 Needleless infusion devices. Medication in a needleless syringe can be inserted into a needleless infusion device. (From Kee JL, Marshall SM: *Clinical calculations,* ed. 7, St. Louis, 2013, Elsevier.)

pharmacist and the drug circular are also resources for infusion guidelines. Guidelines and protocols help to prevent drug and fluid incompatibility.

The current trend to IV medication administration is the use of premixed IV drugs in 50- to 500-mL bags. These premixed IV medications are prepared by the manufacturer or by the hospital pharmacy. The problems of contamination and drug errors are decreased with the use of premixed IV medications. Each IV drug bag has separate tubing to prevent admixture. The cost is higher, but the risk is lower with the use of premixed IV drug bags. Because not all medication can be premixed in the solution, nurses will continue to prepare some drugs for IV administration.

Note: When using a calibrated cylinder such as the Buretrol, add 15 mL of IV solution to flush the drug out of the IV line after the drug infusion is completed. The flush volume is added to the patient's intake. Check hospital policy.

INTERMITTENT INFUSION ADAPTERS/ DEVICES

When continuous IV fluid infusion is to be discontinued and intermittent drug therapy is to begin, an adapter is attached to the IV catheter or needle where the IV tubing was disconnected. Adapters have ports (stoppers) where needles, needleless, or IV tubing can be inserted as needed to continue drug therapy. The use of adapters increases the patient's mobility by not having an IV line "tagging along" and is cost-effective because less IV tubing, solution, and equipment are needed. Figure 14E-3 shows examples of needleless infusion devices.

DIRECT INTRAVENOUS INJECTIONS

Medications that are given by the IV injection route are calculated in the same manner as medications for intramuscular

(IM) injection. This route is often referred to as **IV push.** Clinically, it is the preferred route for patients with poor muscle mass or decreased circulation or for a drug that is poorly absorbed from the tissues. Medications administered by this route have a rapid onset of action, and calculation errors can have serious, even fatal, consequences. The nurse must read drug information inserts carefully and must give attention to the amount of drug that can be given per minute. If the drug is pushed into the bloodstream at a faster rate than specified in the drug literature, adverse reactions to the medication are likely to occur.

ELECTRONIC INTRAVENOUS REGULATORS

Pumps are **electronic intravenous (IV) regulators** used in hospitals and some community settings. The electronic IV regulators are set to deliver a prescribed rate of IV solution. If the flow rate is obstructed, an alarm sounds.

IV pumps deliver IV solution against resistance. The flow rate is set in milliliters per hour. Pumps do not recognize infiltration. The alarm does not sound until the pump has exerted its maximum pressure to overcome resistance.

EXAMPLE

Order: Lasix 80 mg, IV, STAT
Available: Lasix 10 mg/mL. IV infusion not to exceed 40 mg/min

a. RP: $H : V :: D : x$

$$10\text{ mg} : 1\text{ mL} :: 80\text{ mg} : x$$
$$10x = 80$$
$$x = 8\text{ mL of Lasix}$$

or

$$\text{DA: mL} = \frac{1\text{ mL} \times \overset{8}{\cancel{80}}\ \cancel{\text{mg}}}{\underset{1}{\cancel{10}}\ \cancel{\text{mg}} \times 1} = 8\text{ mL of Lasix}$$

b. known drug minutes : known minutes :: desired drug : desired minutes

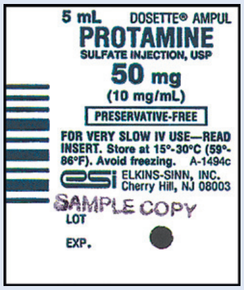
$$40\text{ mg} : 1\text{ min} :: 80\text{ mg} : x$$
$$40x = 80$$
$$x = 2\text{ min}$$

PRACTICE PROBLEM 2

Direct IV Injection

1. Order: protamine sulfate 40 mg IV, STAT

Available:



5 mL DOSETTE® AMPUL
PROTAMINE
SULFATE INJECTION, USP
50 mg
(10 mg/mL)
PRESERVATIVE-FREE
FOR VERY SLOW IV USE—READ INSERT. Store at 15°-30°C (59°-86°F). Avoid freezing. A-1494c
esi ELKINS-SINN, INC. Cherry Hill, NJ 08003
SAMPLE COPY
LOT
EXP.

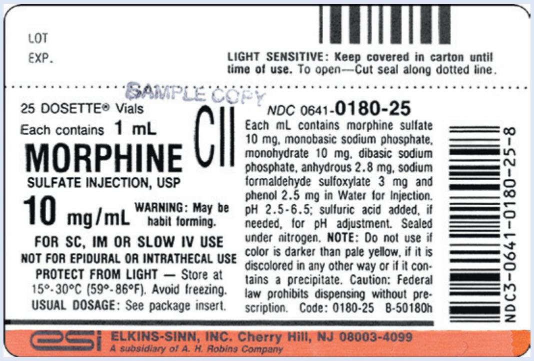
IV infusion not to exceed 5 mg/min

a. How many milliliters should the patient receive? _______

b. For how many minutes should protamine be administered? _______

2. Order: morphine sulfate 5 mg IV, q3h, PRN

Available:



LOT
EXP.
LIGHT SENSITIVE: Keep covered in carton until time of use. To open—Cut seal along dotted line.
SAMPLE COPY
25 DOSETTE® Vials
Each contains 1 mL
MORPHINE CII
SULFATE INJECTION, USP
10 mg/mL
WARNING: May be habit forming.
FOR SC, IM OR SLOW IV USE
NOT FOR EPIDURAL OR INTRATHECAL USE
PROTECT FROM LIGHT — Store at 15°-30°C (59°-86°F). Avoid freezing.
USUAL DOSAGE: See package insert.
NDC 0641-0180-25
Each mL contains morphine sulfate 10 mg, monobasic sodium phosphate, monohydrate 10 mg, dibasic sodium phosphate, anhydrous 2.8 mg, sodium formaldehyde sulfoxylate 3 mg and phenol 2.5 mg in Water for Injection. pH 2.5-6.5; sulfuric acid added, if needed, for pH adjustment. Sealed under nitrogen. NOTE: Do not use if color is darker than pale yellow, if it is discolored in any other way or if it contains a precipitate. Caution: Federal law prohibits dispensing without prescription. Code: 0180-25 B-50180h
NDC3-0641-0180-25-8
esi ELKINS-SINN, INC. Cherry Hill, NJ 08003-4099
A subsidiary of A. H. Robins Company

IV infusion not to exceed 10 mg/4 min

a. How many milliliters should the patient receive? _______

b. For how many minutes should morphine be administered? _______

Note: When giving drugs by direct IV infusion, always verify the compatibility of the IV solution and the drug, or precipitation can result. Incompatibility can be avoided if the IV tubing is flushed with compatible solution of either normal saline or sterile water before and after administration.

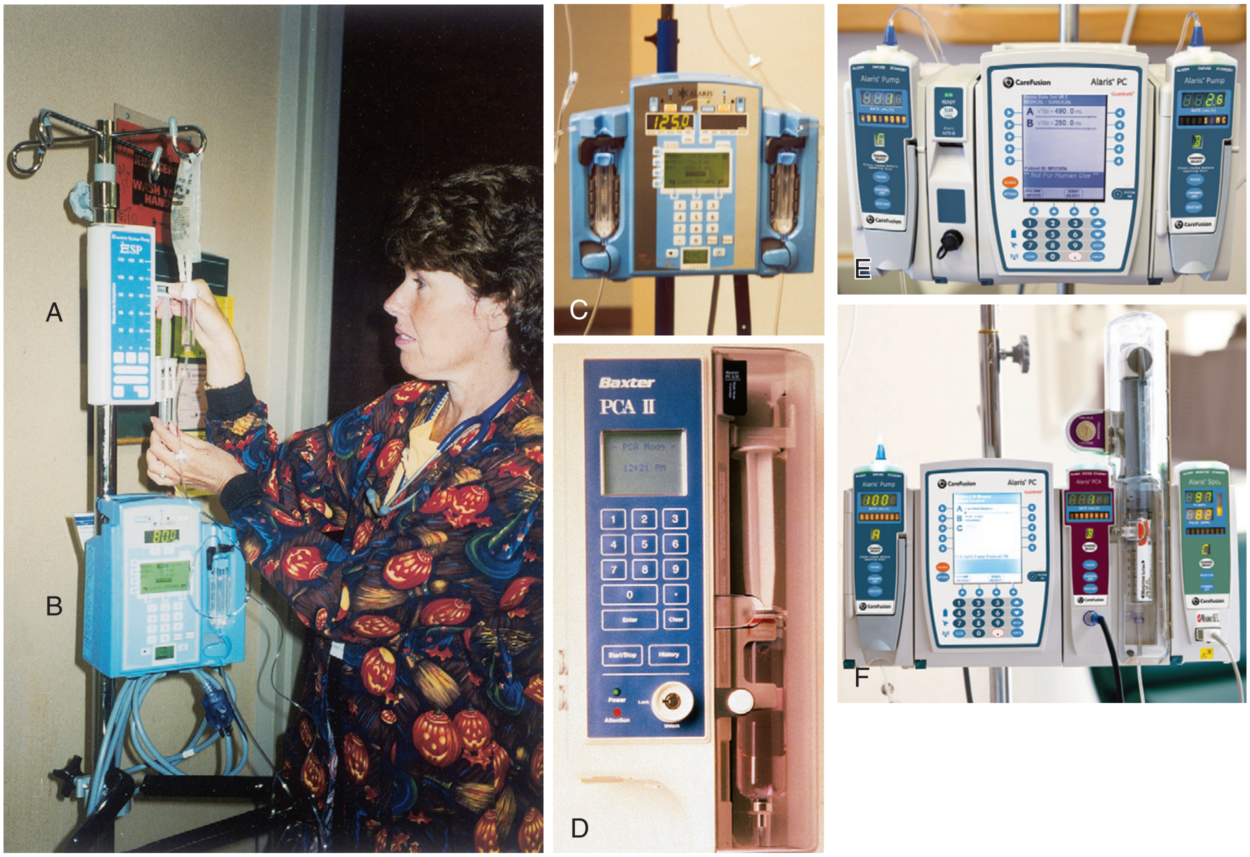


FIGURE 14E–4 Multichannel infusion pump. **A,** Syringe pump. **B,** Single-infusion pump. **C,** Dual-channel infusion pump. **D,** Patient-controlled analgesia (PCA) pump. **E,** Alaris System Large Volume Pump with PCA. **F,** Medley pump module attached to Medley programming module. (From Kee JL, Marshall SM: *Clinical calculations,* ed. 7, St. Louis, 2013, Elsevier.)

IV pumps are recommended for use with all central lines, such as femoral and subclavian sites, and peripheral lines. Ongoing nursing assessment is essential when using electronic IV regulators.

There are two types of flow control for electronic IV regulators: volumetric and nonvolumetric regulators. A **volumetric regulator** delivers a specific volume of fluid at a specific rate, in milliliters per hour. A **nonvolumetric regulator** is designed to infuse at a drop rate in drops per minute. To determine whether the machine is volumetric or nonvolumetric, check to see whether the panel display is calibrated for mL/h or gtt/min. Figure 14E-4 shows a variety of electronic IV regulators for the administration of IV fluids and drugs.

Safety Considerations for IV Use

All IV infusions should be checked every half-hour or hour, according to the policy of the institution. Common problems associated with IV infusions are kinked tubing, infiltration, and "free flow" IV rates. If IV tubing kinks, the flow is interrupted and the prescribed amount of fluid will not be given. The access site can clot. When infiltration occurs, IV fluid extravasates into the tissues and not into the vascular space. Trauma occurs to the tissues at the IV site. "Free flow" IV rate refers to a rapid infusion of IV fluids, thus faster than prescribed, causing fluid overload. Because of the possibility of free flow IV rate, electronic infusion pumps are commonly used today.

Electronic and volumetric infusion pumps are not without flaws. Mechanical problems can occur. Also, incorrectly programming an infusion pump can result in an incorrect infusion rate. Frequent monitoring of IV infusions can prevent complications of IV therapy such as fluid overload, thrombus formation, and infiltration.

Infusion Pumps

Various types of infusion pumps are shown in Figure 14E-4. Part A shows a syringe pump, Part B shows a single-infusion pump, and Part C shows a dual-channel infusion pump. Part D shows a patient-controlled analgesia (PCA) pump, Part E shows the Alaris System Large-Volume pump with PCA, and Part F shows the Medley pump module attached to the Medley programming module.

PATIENT-CONTROLLED ANALGESIA

Patient-controlled analgesia (PCA) is another method used to administer drugs IV. The objective of PCA is to provide a uniform serum concentration of drug(s), thus avoiding drug peaks and valleys. This method is designed to meet the needs of patients who require at least 24 to 48 hours of regular IM narcotic injections.

Several reasons for the use of PCA include (1) effective pain control without the patient feeling oversedated, (2) considerable reduction in the amount of narcotic used (approximately one half that of IM delivery), and (3) patients' feelings of having greater control over their pain.

There are choices available in the delivery of PCA. The pump is programmed to administer the prescribed medication (1) at patient demand, (2) continuously, and (3) continuously and supplemented by patient demand (see Chapter 13).

The health care provider's order must include the following:

- Drug ordered
- Loading dose: administered by the health care provider to obtain baseline serum concentration of analgesic
- PCA dose: amount to be administered each time patient activates the button
- Lockout interval: time during which PCA cannot be administered
- Dose limit: the maximum amount the patient can receive during a specified time

Patient Teaching

- Inform the patient that the pain should be tolerable, not necessarily absent.
- Advise the patient of the pump's safety features, including the alarms.
- Instruct the patient in the use of the control button (medication administered when button is *released*).
- Instruct the patient to report any side effects or adverse reactions to the medication.
- Have naloxone (Narcan) easily accessible.

CALCULATING FLOW RATES FOR INTRAVENOUS DRUGS

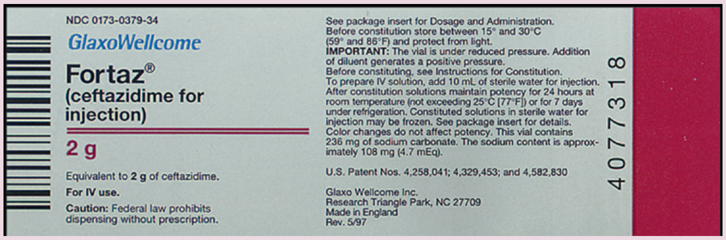
IV drug infusion rates depend on the drug dosing instructions, which indicate the amount of solution for dilution, and the length of infusion time. The nurse must first calculate the drug dose from the health care provider's order, and then calculate the flow rate.

1. *Secondary Sets:* To find drops per minute for IV drugs, use calibrated cylinders (Buretrol, Volutrol), 50- to 250-mL bag (Add-A-Line), or any other nonvolumetric regulator.
2. *Volumetric Regulators:* To find milliliters per hour (Infusion rate)

Problems for calculating IV drug dosage and IV flow rate in drops per minute and in milliliters per hour are given below.

EXAMPLE

Order: ceftazidime (Fortaz) 1.5 g IV q6h
Available:



NDC 0173-0379-34
GlaxoWellcome
Fortaz®
(ceftazidime for injection)
2 g
Equivalent to **2 g** of ceftazidime.
For IV use.
Caution: Federal law prohibits dispensing without prescription.

See package insert for Dosage and Administration.
Before constitution store between 15° and 30°C (59° and 86°F) and protect from light.
IMPORTANT: The vial is under reduced pressure. Addition of diluent generates a positive pressure.
Before constituting, see Instructions for Constitution.
To prepare IV solution, add 10 mL of sterile water for injection.
After constitution solutions maintain potency for 24 hours at room temperature (not exceeding 25°C [77°F]) or for 7 days under refrigeration. Constituted solutions in sterile water for injection may be frozen. See package insert for details.
Color changes do not affect potency. This vial contains 236 mg of sodium carbonate. The sodium content is approximately 108 mg (4.7 mEq).

U.S. Patent Nos. 4,258,041; 4,329,453; and 4,582,830

Glaxo Wellcome Inc.
Research Triangle Park, NC 27709
Made in England
Rev. 5/97

4077318

Set and solution: Cylinder set with drop factor of 60 gtt/mL; 500 mL of D_5W.
Instruction: Dilute ceftazidime 1.5 g in 100 mL of D_5W and infuse over 30 minutes.

1. Calculate drug dosage according to drug label.
2. Calculate drops per minute for drug solution.
3. Calculate milliliters per hour using volumetric infusion pump rate (mL/h).

Answer

1. Drug Calculation
   Drug label states to add 10 mL of sterile water (2g = 10 mL)

$$\text{BF: } \frac{D}{H} \times V = \frac{1.5\text{ g}}{2\text{ g}} \times 10\text{ mL} = \frac{15}{2} = 7.5\text{ mL of ceftazidime}$$

$$\text{DA: mL} = \frac{10\text{ mL} \times 1.5\,\cancel{\text{g}}}{2\,\cancel{\text{g}} \times 1} = \frac{15}{2} = 7.5\text{ mL}$$

2. Secondary Set

$$\frac{\text{Amount of solution} \times \text{Drops per milliliter (set)}}{\text{Minutes to administer}} = \frac{100\text{ mL} \times \overset{2}{\cancel{60}}\text{ gtt}}{\underset{1}{\cancel{30}}\text{ min}} = 200\text{ gtt/min}$$

Inject 7.5 mL of ceftazidime in 100 mL of D_5W in the cylinder chamber.

Regulate IV flow rate to 200 gtt/min. It may be impossible to count 200 gtt/min. Instead of using the cylinder chamber, the nurse may use a secondary set that has a larger drop factor or a regulator. If the cylinder set is the only available secondary IV set, then the 200 gtt/min may be approximated.

3. Volumetric Infusion Pump Rate

$$\text{Amount of solution} \div \frac{\text{Minutes to administer}}{\text{60 minutes per hour}} = 100\text{ mL} + 7.5\text{ mL (drug)} \div \frac{30\text{ min}}{60\text{ min}} =$$

$$\text{(invert divisor and multiply) } 107.5\text{ mL} \times \frac{\overset{2}{\cancel{60}}}{\underset{1}{\cancel{30}}} = 215\text{ mL/h}$$

Set volumetric infusion rate at 215 mL/h to deliver drug in 30 min.

PRACTICE PROBLEM 3

Intermittent Intravenous Set

Solve the IV drug problems by (1) calculating the drug dosage according to the drug label or information given and (2) calculating drops per minute for the drug solution.

1. Order: kanamycin (Kantrex) 15 mg/kg/day in three divided doses (q8h) IV Patient weighs 50 kg.

   Available:

ANSWERS TO PRACTICE PROBLEMS

1 CONTINUOUS INTRAVENOUS FLOW RATES

1. a. Microdrip set because the patient is to receive 83 mL/h
   b. Two-step method: for continuous IV flow rate

   Step 1. $\frac{1000}{12} = 83\text{ mL/h}$

   Step 2. $\frac{83\text{ mL/h} \times \overset{1}{\cancel{60}}\text{ drobs}}{\underset{1}{\cancel{60}}\text{ min}} = 83\text{ gtt/min}$

2. a. 1000 mL
   b. 8 h
   c. Step 1. $\frac{1000}{8} = 125\text{ mL/h}$

   Step 2. $\frac{125\text{ mL/h} \times \overset{1}{\cancel{15}}\text{ gtt}}{\underset{4}{\cancel{60}}\text{ min}} = \frac{125}{4} = 31\text{ gtt/min}$

3. a. Microdrip set
   b. Step 1. $\frac{250}{44} = 10\text{ mL/h}$

   Step 2. $\frac{10\text{ mL/h} \times \overset{1}{\cancel{60}}\text{ gtt}}{\underset{1}{\cancel{60}}\text{ min}} = 10\text{ gtt/min}$

4. a. KCl: BF: $\frac{D}{H} \times V = \frac{10}{20} \times 20 = \frac{200}{20} = 10\text{ mL KCl}$
   b. $\frac{1000}{10} = 100\text{ mL/h}$

   Macrodrip set $\frac{100 \times \overset{1}{\cancel{15}}}{\underset{4}{\cancel{60}}\text{ min}} = 25\text{ gtt/min}$

   Microdrip set $\frac{100 \times \overset{1}{\cancel{60}}}{\underset{1}{\cancel{60}}\text{ min}} = 100\text{ gtt/min}$

2 DIRECT IV INJECTION

1. a. BF: $\frac{D}{H}\times V = \frac{40\ \cancel{mg}}{10\ \cancel{mg}}\times 1\ mL = 4\ mL$

   DA: $mL = \frac{1\ mL \quad \times 40\ \cancel{mg}}{10\ \cancel{mg}\times 1} = \frac{40}{10} = 4\ mL$

   b. known drug : known min :: desired drug : desired min

   5 mg : 1 min :: 40 mg : x

   $5x = 40$

   $x = 8$ min

2. a. RP: H : V :: D : x

   10 mg : 1 mL :: 5 mg : x

   $10x = 5$

   $x = \frac{5}{10} = \frac{1}{2}$ or 0.5 mL drug

   b. known drug : known min :: desired drug : desired min

   10 mg : 4 min :: 5 mg : x

   $10x = 20$

   $x = 2$ min

3 INTERMITTENT INTRAVENOUS SET

1. a. 750 mg per day

   b. Drug calculation for q8h; 250 mg per dose.

   BF: $\frac{D}{H}\times V = \frac{250\ \cancel{mg}}{500\ \cancel{mg}}\times 2 = \frac{500}{500} = 1\ mL$ of kanamycin

   or

   RP: H : V :: D : x

   500 mg : 2 mL :: 250 mg : x mL

   $500x = 500$

   $x = 1$ mL of kanamycin

   c. IV flow calculation: $\frac{75\ mL \times 60\ (set)}{30\ min} = \frac{4500}{30}$

   $= 150$ gtt/min

2. a. Drag calculation: BF: $\frac{D}{H}\times V = \frac{50}{80}\times 2 = \frac{100}{80}$

   $= 1.25$ mL of tobramycin

   b. IV flow calculation: $\frac{100\ mL \times \overset{3}{\cancel{60}}\ gtt\ (set)}{\underset{2}{\cancel{40}}\ min}$

   $= \frac{300}{2} = 150$ gtt/min

   c. Drug parameter: It is within safe parameters (3 kg × 65 = 195 mg/day)

   Patient is receiving 50 mg × 3 = 150 mg/day (less than drug parameter)

3. a. Drug calculation: Convert to milligrams.

   $2\ g = 2.\underset{\smile}{000}\ mg$

   BF: $\frac{D}{H}\times V = \frac{500}{2000}\times 5 = \frac{5}{4} = 1.25\ mL$ of ampicillin

   or

   RP: H : V :: D : x

   2000 mg : 5 mL :: 500 mg : x mL

   $2000x = 2500$

   $x = 1.25$ mL of ampicillin

   b. IV flow calculation:

   $\frac{50\ mL \times \overset{4}{\cancel{60}}\ gtt\ (set)}{\underset{1}{\cancel{15}}\ min} = \frac{200}{1} = 200$ gtt/min

   c. Volumetric infusion pump rate:

   $50\ mL + 1.25\ mL \div \frac{15}{60} = 51.25\ mL \times \frac{\overset{4}{\cancel{60}}}{\underset{1}{\cancel{15}}} = 205\ mL/hr$

4. Drug label = Add 4 mL of sterile water.

   a. BF: $\frac{D}{H}\times V = \frac{750\ \cancel{mg}}{1000\ \cancel{mg}}\times 4\ mL = \frac{3000}{1000}$

   $= 3$ mL of Ticar

   or

   DA: $mL = \frac{4\ mL \quad \times 1\ \cancel{g} \quad \times \overset{3}{\cancel{750}}\ \cancel{mg}}{1\ \cancel{g} \quad \times \underset{4}{\cancel{1000}}\ \cancel{mg}\times 1} = \frac{12}{4}$

   $= 3$ mL of Ticar

   b. IV flow calculation: $\frac{20\ mL \times \overset{2}{\cancel{60}}\ gtt\ (set)}{\underset{1}{\cancel{30}}\ min} = \frac{40}{1}$

   $= 40$ gtt/min

c. Volumetric infusion pump rate:

$$20\text{ mL} + 3\text{ mL} + \frac{30}{60} = 23\text{ mL} \times \frac{\overset{2}{\cancel{60}}}{\underset{1}{\cancel{30}}} = 46\text{ mL/h}$$

(Increase in D_5W solution may be desired)

5. a. $0.1\text{ g} = 0.\underset{\curvearrowright}{100}\text{ mg} = 100\text{ mg}$

b. $\text{BF: } \frac{D}{H} \times V = \frac{\overset{1}{\cancel{100}}\text{ }\cancel{\text{mg}}}{\underset{2}{\cancel{200}}\text{ }\cancel{\text{mg}}} \times 20\text{ mL} = \frac{20}{2} = 10\text{ mL}$

$$\text{DA: mL} = \frac{20\text{ mL} \quad \times \overset{1}{\cancel{100}}\text{ }\cancel{\text{mg}}}{\underset{2}{\cancel{200}}\text{ }\cancel{\text{mg}} \times 1} = \frac{20}{2} = 10\text{ mL}$$

c. $\frac{10\text{ mL} + 100\text{ mL} \times 15\text{ gtt/mL (set)}}{60\text{ min to admin}} = \frac{100 \times \overset{1}{\cancel{15}}}{\underset{4}{\cancel{60}}} =$

27.5, or 28 gtt/min

d. $10\text{ mL} + 100\text{ mL} \div \frac{\overset{1}{\cancel{60}}\text{ min to admin}}{\underset{1}{\cancel{60}}\text{ min/h}} = 110\text{ mL/h}$

6. a. 1 mg = 1000 mcg

b. Drug parameters: 0.3 mcg × 75 kg = 22.5 mcg
OR 0.0225 or 0.023 mg/minutes
8 mcg × 75 kg = 600 mcg OR 0.600 mg/minutes
0.023 mg × 90 min = 2.07 mg per 90 minutes
0.600 mg × 90 min = 54 mg per 90 minutes

c. Yes. Range: 2.07 to 54 mg per 90 minutes is within range of 40 mg to administer.

d. Drug calculation:

$$\text{BF: } \frac{D}{H} \times V = \frac{40\text{ mg}}{50\text{ mg}} \times 2\text{ mL} = \frac{80}{50} = 1.6\text{ mL of Nitropress}$$

$$\text{FE: } \frac{H}{V} = \frac{D}{x} = \frac{50\text{ mg}}{2\text{ mL}} = \frac{40\text{ mg}}{x}$$

(cross-multiply) $50x = 80$

$x = 1.6$ mL of Nitropress to add to IV fluid

e. Infusion Pump Rate:

$$\text{Amount of solution} \div \frac{\text{minutes to administer}}{\text{60 minutes (hr)}} = \text{mL/hr}$$

$$250 \div \frac{\text{90 minutes}}{\text{60 minutes}} = \text{Invert divisor and multiple}$$

$$250 \times \frac{\overset{2}{\cancel{60}}}{\underset{3}{\cancel{90}}} = \frac{500}{3} = 166.66\text{ or 167 mL/hr (round off to whole numbers)}$$

7. a. 165 pounds ÷ 2.2 = 75 kg

b. Yes, dose is within safe drug parameters.

3 mg × 75 kg = 225 mg divided by 3 doses = 75 mg

5 mg × 75 kg = 375 mg divided by 3 doses = 125 mg

c. $\text{BF: } \frac{D}{H} \times V = \frac{100\text{ }\cancel{\text{mg}}}{80\text{ }\cancel{\text{mg}}} \times 2\text{ mL} = \frac{200}{80} = 2.5\text{ mL}$

$$\text{DA: mL} = \frac{2\text{ mL} \quad \times \overset{5}{\cancel{100}}\text{ }\cancel{\text{mg}}}{\underset{4}{\cancel{80}}\text{ }\cancel{\text{mg}} \times 1} = \frac{10}{4} = 2.5\text{ mL}$$

d. $\frac{75\text{ mL} \times \overset{3}{\cancel{60}}\text{ gtt/ mL (set)}}{\underset{2}{\cancel{40}}\text{ min to admin}} = \frac{225}{2} = 112.5\text{ gtt/min}$

e. $75\text{ mL} \div \frac{40\text{ min to admin}}{60\text{ min/h}} =$

(invert divisor and multiply) $75 \times \frac{\overset{3}{\cancel{60}}}{\underset{2}{\cancel{40}}} = \frac{225}{2}$

112.5, or 113 mL/h

8. a. Patient's BSA is 1.75.

b. 75 mg × 1.75 (BSA) = 131.25 or 131 mg

c. $\frac{D}{H} \times V = \frac{131}{150} \times 7.5\text{ mL} = \frac{982.5}{150} = 6.55\text{, or 6.6 mL}$

IV flow calculation with secondary set:

$$\frac{250\text{ mL} \times 15\text{ gtt (set)}}{60\text{ min}} = \frac{3750}{60} = 62.5\text{ gtt/nun}$$

Volumetric pump rate: 250 mL + 6.6 mL

$$(256.6\text{ or 257 mL}) \div \frac{60}{60} = 257\text{ mL} \times \frac{\overset{1}{\cancel{60}}}{\underset{1}{\cancel{60}}}$$

$= 257$ mL/h

Section 14F: Pediatric Drug Calculations

OBJECTIVES

- Use one of the two primary methods to determine pediatric drug dosage.
- Describe the dosage inaccuracies that may occur with pediatric drug formulas.
- Identify the steps used to determine body surface area from a pediatric nomogram.
- Calculate the drug dosages correctly in the practice problems.

OUTLINE

Key Terms
Oral
Intramuscular
Pediatric Dosage per Body Weight
Pediatric Dosage per Body Surface Area
Pediatric Calculations for Injectables

KEY TERMS

body surface area (BSA) or m^2, p. 202

body weight (BW), p. 202

Pediatric drug dosages differ greatly from those for adults because of the physiologic differences between the two. Neonates and infants have immature kidney and liver function, which delays metabolism and elimination of many drugs. In neonates, drug absorption is different as a result of slow gastric emptying time. Decreased gastric acid secretion in children younger than 3 years of age contributes to altered drug absorption. Neonates and infants have a lower concentration of plasma proteins, which can cause toxicity with drugs that are highly bound to proteins. Young children have less total body fat and more body water; therefore lipid-soluble drugs require smaller doses when less-than-normal fat is present. Water-soluble drugs can require large doses because of a greater percentage of body water. It is the nurse's responsibility to ensure that a safe drug dosage is given and to closely monitor signs and symptoms of side effects and adverse drug reactions.

The purpose of learning how to calculate pediatric drug dosages is to ensure that children receive the correct dose within the approved therapeutic range. The two methods that are considered safe in the administration of drugs to children are the **body weight (BW)** (kg) and **body surface area (BSA)** or m^2 methods. Many manufacturers supply information in their literature concerning drug doses for children according to BW. Also, manufacturers frequently give drug parameters for safe dose ranges. It is the nurse's responsibility to check the dose ranges given by the pharmaceutic manufacturers to be certain that the prescribed dose is within the parameters.

ORAL

Oral pediatric drug delivery usually requires the use of a calibrated measuring device because most drugs for small children are in liquid form. The measuring device can be a small plastic cup, an oral dropper, a measuring spoon, or an oral syringe (Figure 14F-1). Some liquid medications come with their own calibrated droppers. The type of measuring device chosen depends on the age or the developmental level of the child. For infants and toddlers, the oral syringe and dropper can provide better drug delivery than a small cup. A young child who is cooperative is able to use a small cup or measuring spoon. The cup or spoon may be rinsed with water or juice to ensure that the child has received all of the drug. Avoid giving oral medications to a crying child or infant because the drug could be easily aspirated or the child could "spit out" the drug. For the older child, some drugs are available in chewable form. Children should be told not to chew drugs that are enteric-coated or in time-release form.

INTRAMUSCULAR

Intramuscular (IM) sites for drug administration are chosen on the basis of the age and muscle development of the child (Table 14F-1). All injections should be given in a manner that minimizes physical and psychosocial trauma. Explanations of injection administration should be given to children who can comprehend. With the very young child, distraction or brief restraint may be necessary. Comfort measures should immediately follow the injection.

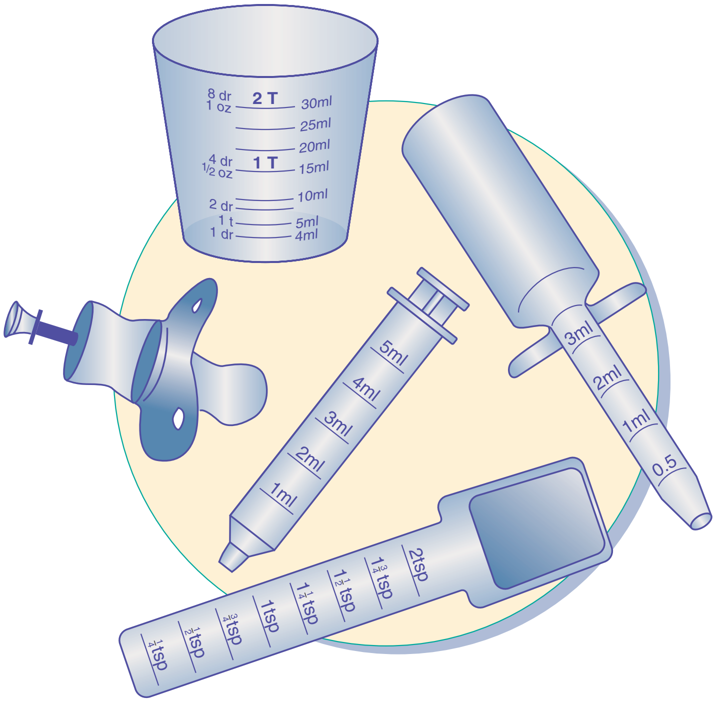

FIGURE 14F–1 Calibrated measuring devices. (From Kee JL, Marshall SM: *Clinical calculations,* ed. 7, St. Louis, 2013, Elsevier.)

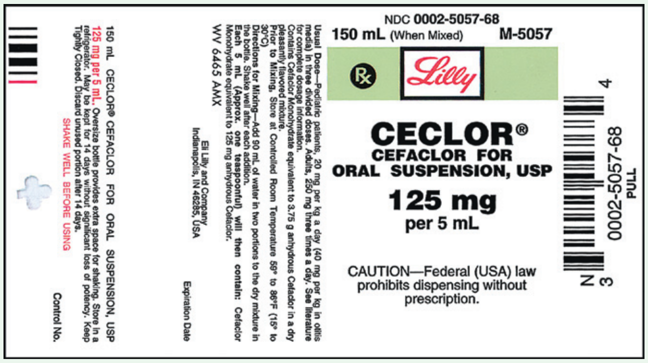
PEDIATRIC DOSAGE PER BODY WEIGHT

EXAMPLE

Order: cefaclor (Ceclor) 50 mg q.i.d. Child weighs 15 lb or 6.8 kg (15 ÷ 2.2 = 6.8).

Child's drug dosage: 20 to 40 mg/kg/day in 3 divided doses

Available:



150 mL CECLOR® CEFACLOR FOR ORAL SUSPENSION, USP
125 mg per 5 mL. Oversize bottle provides extra space for shaking. Store in a refrigerator. May be kept for 14 days without significant loss of potency. Keep Tightly Closed. Discard unused portion after 14 days.
SHAKE WELL BEFORE USING
Control No.

Usual Dose—Pediatric patients, 20 mg per kg a day (40 mg per kg in otitis media) in three divided doses. Adults, 250 mg three times a day. See literature for complete dosage information.
Contains Cefaclor Monohydrate equivalent to 3.75 g anhydrous Cefaclor in a dry pleasantly flavored mixture.
Prior to Mixing. Store at Controlled Room Temperature 59° to 86°F (15° to 30°C)
Directions for Mixing—Add 90 mL of water in two portions to the dry mixture in the bottle. Shake well after each addition.
Each 5 mL (Approx. one teaspoonful) will then contain: Cefaclor Monohydrate equivalent to 125 mg anhydrous Cefaclor.

PULL

Is the prescribed dose safe? _____

Answer:

Drug parameters: 20 mg × 6.8 kg = 136 mg/day

40 mg × 6.8 kg = 272 mg/day

Dosage order: 50 mg × 4 = 200 mg/day

Dosage is within safe drug parameters.

a. BF: $\frac{D}{H} \times V = \frac{50}{125} \times 5 = \frac{250}{125} = 2\text{ mL}$

b. RP: $\text{H} : \text{V} :: \text{D} : x$

$$\underbrace{125\text{ mg} : \underbrace{5\text{ mL} :: 50\text{ mg}} : x\text{ mL}}$$

$$125x = 250$$

$$x = 2\text{ mL (cc)}$$

c. FE: $\frac{H}{V} = \frac{D}{x} \quad \frac{125\text{ mg}}{5\text{ mL}} = \frac{50\text{ mL}}{x\text{ mL}}$

(cross-multiply) $125x = 250$

$$x = 2\text{ mL}$$

d. DA: $\text{mL} = \frac{5\text{ mL} \times \overset{2}{\cancel{50}}\,\cancel{\text{mg}}}{\underset{5}{\cancel{125}}\,\cancel{\text{mg}} \times 1} = \frac{10}{5} = 2\text{ mL}$

Cefaclor 50 mg = 2 mL. Give 2 mL 4 times a day.

PEDIATRIC DOSAGE PER BODY SURFACE AREA

To calculate pediatric dose by BSA, the child's height and weight are needed. Figure 14F-2 is the nomogram used to determine the BSA for infants and children. The square root formula may be used for BSA.

$$\text{BSA} = \frac{\sqrt{\text{height (in)} \times \text{weight (lb)}}}{3131\,\text{(constant)}}$$

TABLE 14F-1 PEDIATRIC GUIDELINES FOR INTRAMUSCULAR INJECTIONS ACCORDING TO MUSCLE GROUP*

	AMOUNT BY MUSCLE GROUP (mL)					
	VASTUS LATERALIS	**RECTUS FEMORIS**	**VENTROGLUTEAL**	**DORSAL GLUTEAL**	**GLUTEUS MAXIMUS**	**DELTOID**
Neonates	0.5 mL	Not safe	Not safe	Not safe	Not safe	Not safe
Infants 1-12 months	0.5-1 mL	Not safe	Not safe	Not safe	Not safe	Not safe
Toddlers 1-2 years	0.5-2 mL	0.5-1 mL	Not safe	Not safe	Not safe	0.5-1 mL
Preschool to child 3-12 years	2 mL	2 mL	0.5-3 mL	0.5-2 mL	0.5-2 mL	0.5-1 mL
Adolescent 12-18 years	2 mL	2 mL	2-3 mL	2-3 mL	2 mL	1-1.5 mL

*The safe use of all sites is based on normal muscle development and size of the child. Follow institutional policies and procedures. In some institutions, the dorsal gluteal site is prohibited. (From Kee JL, Marshall SM: *Clinical calculations*, ed. 7, St. Louis, 2013, Elsevier.)

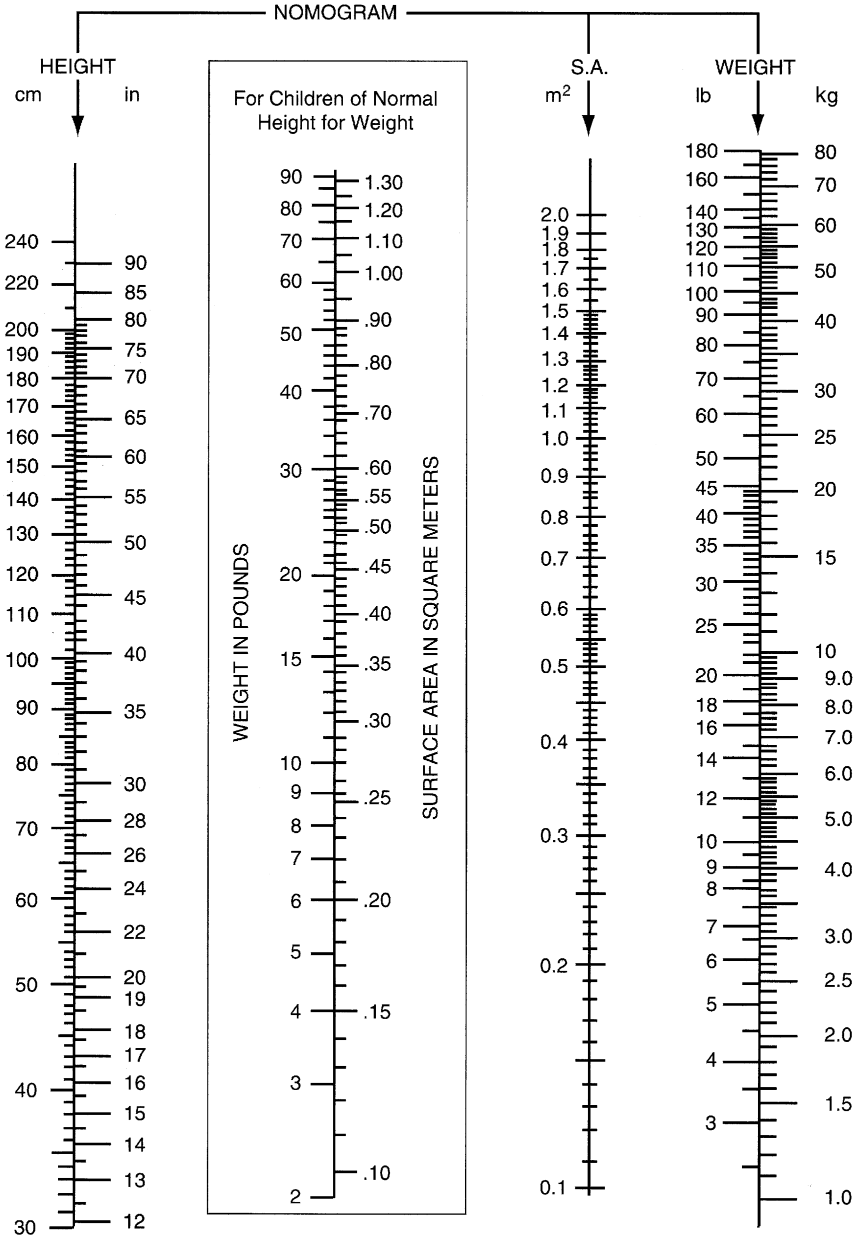

FIGURE 14F–2 Nomogram of body surface area for infants and children. Directions: (1) Find height. (2) Find weight. (3) Draw a straight line that connects the height and weight. (4) Where the line intersects on the body surface area column is the body surface area (m^2). (Sources: Deglin J, Vallerand A, Russin A: *Davis's drug guide for nurses,* ed. 2, Philadelphia, 1991, FA Davis; Lentner C (ed): *Geigy scientific tables,* ed. 8, vol. 1, Basle, Switzerland, 1981, Ciba-Geigy, pp. 226-227. In RE Behrman, RM Kliegman, HB Jensen: *Nelson textbook of pediatrics,* ed. 18, Philadelphia, 2007, Saunders.)

EXAMPLE

Order: methotrexate (Mexate) 50 mg weekly. Child's height is 54 inches and weight is 90 lb (41 kg).

Child's drug dosage: 25 to 75 mg/m^2/week

Child's height and weight intersect at 1.3 m^2 (BSA).

Is the prescribed dose safe? ______

Answer:

Multiply the BSA, 1.3 m^2, by the minimum and maximum doses.

$$25 \text{ mg} \times 1.3 \text{ m}^2 = 32.5 \text{ mg}$$
$$75 \text{ mg} \times 1.3 \text{ m}^2 = 97.5 \text{ mg}$$

$$\text{BSA by square root: } \frac{\sqrt{54 \text{ in} \times 90 \text{ lb}}}{3131} = \text{m}^2 = 1.55$$
$$25 \text{ mg} \times 1.55 \text{ m}^2 = 38.5 \text{ mg}$$
$$75 \text{ mg} \times 1.55 \text{ m}^2 = 116.3 \text{ mg}$$

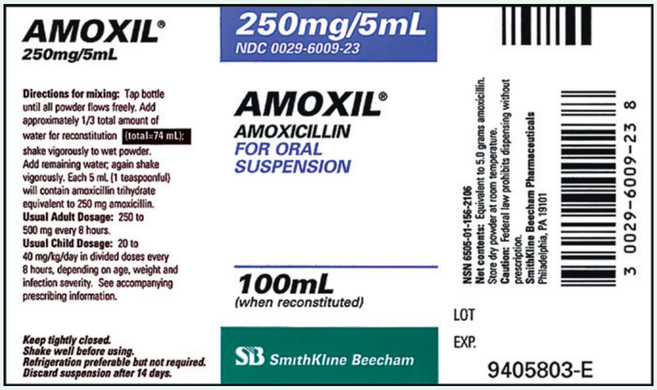
Dosage is considered safe within the parameters according to the child's BSA.

PRACTICE PROBLEM 1

Pediatric Dosing (Oral)

Solve the following problems using the BW or BSA method. The safe dosage is given in drug reference books.

1. Order: dicloxacillin sodium 100 mg q6h. Child weighs 55 lb (25 kg).
   Child's drug dosage range: Less than 40 kg, 12.5 to 25 mg/kg/day
   Available: dicloxacillin 62.5 mg per 5 mL
   a. Is the prescribed dose safe?_______
   b. How many milliliters should be given for each dose? _______
2. Order: digoxin (Lanoxin) 35 mcg/kg/loading dose, PO
   Child weighs 10 kg
   Available: Lanoxin 50 mcg/mL (0.05 mg/mL)
   a. How many micrograms or milligrams should the child receive?_______
   b. How many milliliters should be given for the loading dose?
3. Order: amoxicillin (Amoxil) 200 mg PO q8h. Child weighs 26 lb (12 kg).
   Child's drug dosage: 20 to 40 mg/kg/day in 3 divided doses
   Available:



AMOXIL®
250mg/5mL

Directions for mixing: Tap bottle until all powder flows freely. Add approximately 1/3 total amount of water for reconstitution (total=74 mL); shake vigorously to wet powder. Add remaining water; again shake vigorously. Each 5 mL (1 teaspoonful) will contain amoxicillin trihydrate equivalent to 250 mg amoxicillin.
Usual Adult Dosage: 250 to 500 mg every 8 hours.
Usual Child Dosage: 20 to 40 mg/kg/day in divided doses every 8 hours, depending on age, weight and infection severity. See accompanying prescribing information.

Keep tightly closed.
Shake well before using.
Refrigeration preferable but not required.
Discard suspension after 14 days.

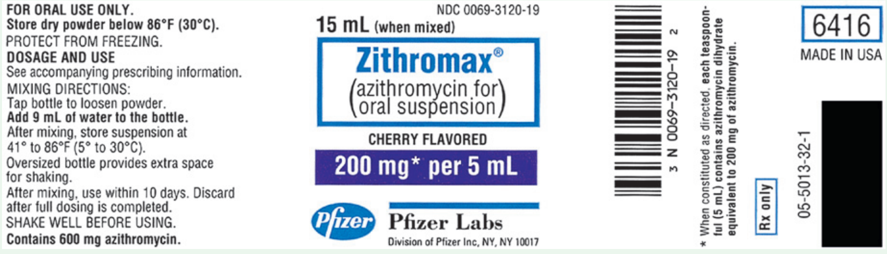
   a. Is the prescribed dose safe?_______
   b. How many milliliters should be given every 8 hours? _______
4. Order: azithromycin (Zithromax), PO. First day: 10 mg/kg/day; next 4 days: 5 mg/kg/day.
   Child weighs 44 lb.
   Available:



FOR ORAL USE ONLY.
Store dry powder below 86°F (30°C).
PROTECT FROM FREEZING.
DOSAGE AND USE
See accompanying prescribing information.
MIXING DIRECTIONS:
Tap bottle to loosen powder.
Add 9 mL of water to the bottle.
After mixing, store suspension at 41° to 86°F (5° to 30°C).
Oversized bottle provides extra space for shaking.
After mixing, use within 10 days. Discard after full dosing is completed.
SHAKE WELL BEFORE USING.
Contains 600 mg azithromycin.

NDC 0003-0681-44 **100 mL**

EQUIVALENT TO
125 mg (200,000 units)
per 5 mL when reconstituted according to directions.

VEETIDS®
Penicillin V Potassium
For Oral Solution, USP

Rx only

To the Pharmacist: Prepare solution at time of dispensing. Add to the bottle a total of **61 mL** of water. For ease in preparation, add the water in 2 portions. Shake well after each addition. This provides 100 mL of solution. Each 5 mL contains penicillin V potassium equivalent to 125 mg (200,000 units) of penicillin V.

PULL DOWN TAB TO OPEN BOOKLET

Control:

Exp. Date of Powder:

   a. How many kilograms (kg) does the child weigh? _______
   b. Is the prescribed dose within safe drug parameters? _______
   c. How many milliliters (mL) of penicillin V should you give per dose? _______

8. Order: vinblastine (Velsar)
   Child's BSA is 1.2 m^2.
   Child's drug dosage: 2.5 mg/m^2
   How many milligrams should the child receive? _______

PEDIATRIC CALCULATIONS FOR INJECTABLES

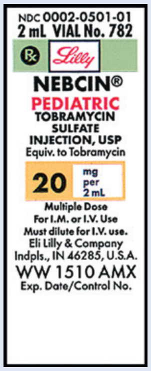
The same methods used to calculate oral dosages for children are used to calculate injectable dosages. They are calculated from (1) BW (kg) and (2) BSA (m^2). Use the nomogram for BSA.

PRACTICE PROBLEM 2

Pediatric Injectables

Solve the following drug problems, and indicate whether the drug dose is within the safe drug parameters.

1. Order: tobramycin (Nebcin) 10 mg IM q8h
   Child weighs 10 kg.
   Child's drug dosage: 3 mg/kg/day in 3 divided doses
   Available:

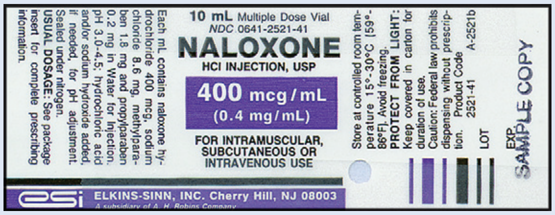


NDC 0002-0501-01
2 mL VIAL No. 782
Lilly
NEBCIN®
PEDIATRIC
TOBRAMYCIN SULFATE INJECTION, USP
Equiv. to Tobramycin
20 mg per 2 mL
Multiple Dose
For I.M. or I.V. Use
Must dilute for I.V. use.
Eli Lilly & Company
Indpls., IN 46285, U.S.A.
WW 1510 AMX
Exp. Date/Control No.

   b. Is the prescribed dose within safe drug parameters? _______
   c. How many milliliters should the child receive per dose? _______

2. Order: promethazine (Phenergan) 20 mg IM q6h
   Child weighs 45 kg.
   Child's drug dosage: 0.25 to 0.5 mg/kg/dose; repeat every 4-6 hours
   Available: Phenergan 25 mg/mL
   a. Is the prescribed dose within safe drug parameters? _______
   b. How many milliliters should the child receive per dose? _______

3. Order: naloxone 0.2 mg IM, STAT
   Child weighs: 44 pounds.
   Child's drug dosage: 0.01 mg/kg
   Available:



Each mL contains naloxone hydrochloride 400 mcg, sodium chloride 8.6 mg, methylparaben 1.8 mg and propylparaben 0.2 mg in Water for Injection. pH 3.0-4.5; hydrochloric acid and/or sodium hydroxide added, if needed, for pH adjustment. Sealed under nitrogen. USUAL DOSAGE: See package insert for complete prescribing information.
10 mL Multiple Dose Vial
NDC 0641-2521-41
NALOXONE
HCl INJECTION, USP
400 mcg/mL
(0.4 mg/mL)
FOR INTRAMUSCULAR, SUBCUTANEOUS OR INTRAVENOUS USE
Store at controlled room temperature 15°-30°C (59°-86°F). Avoid freezing.
PROTECT FROM LIGHT: Keep covered in carton for duration of use.
Caution: Federal law prohibits dispensing without prescription.

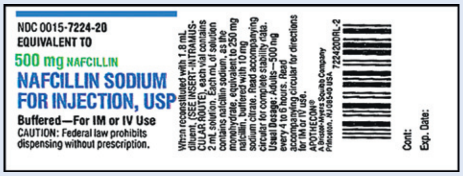
   c. How many milliliters should the child receive? _______

4. Order: nafcillin sodium 200 mg IM q6h
   Child weighs 10 kg.
   Child's drug dosage: 100 to 300 mg/kg/day in divided doses
   Available: 1.8 mL of diluent = 2 mL



NDC 0015-7224-20
EQUIVALENT TO
500 mg NAFCILLIN
NAFCILLIN SODIUM FOR INJECTION, USP
Buffered—For IM or IV Use
CAUTION: Federal law prohibits dispensing without prescription.
When reconstituted with 1.8 mL diluent, (SEE INSERT-INTRAMUSCULAR ROUTE), each vial contains 2 mL solution. Each mL of solution contains nafcillin sodium, as the monohydrate, equivalent to 250 mg nafcillin, buffered with 10 mg sodium citrate. Read accompanying circular for complete stability data. Usual Dosage: Adults—500 mg every 4 to 6 hours. Read accompanying circular for directions for IM or IV use.

   a. How many milligrams should the child receive per day? _______
   b. Is the prescribed dose within safe drug parameters? _______

Continued

c. The drug label does not give the amount of diluent to add to the Ancef powder. Check the pamphlet insert. With 3.4 mL of diluent added, it is equivalent to 4 mL of drug solution.

d. How many milliliters of cefazolin should the child receive per dose? _______

7. Order: hydroxyzine (Vistaril) 50 mg IM
Child's height is 47 inches and weight is 45 lb.
Child's drug dosage: 30 mg/m^2
Available: Vistaril 25 mg/mL
a. Is the prescribed dose within safe drug parameters? ______

8. Order: methotrexate (Mexate) 50 mg IM weekly
Child's height is 56 inches and weight is 100 lb.
Child's drug dosage: 25 to 75 mg/m^2/wk
Available: methotrexate 2.5 mg/mL; 25 mg/mL; 100 mg/mL
a. Is the prescribed dose within safe drug parameters? _______
b. Which methotrexate should be selected? _______

ANSWERS TO PRACTICE PROBLEMS

1 PEDIATRIC DOSING (ORAL) USING BASIC FORMULA, RATIO AND PROPORTION, OR DIMENSIONAL ANALYSIS

1. a. Child weighs 25 kg (55 lb ÷ 2.2 = 25 kg)
Drug parameters:
12.5 mg × 25 kg = 312.5 mg/day
25 mg × 25 kg = 625 mg/day
Dosage order: 100 mg × 4 times a day (q6h) = 400 mg/day
Dosage is within safe drug parameters.

b. $$\text{BF: } \frac{D}{H}\times V = \frac{100}{62.5}\times 5\text{ mL} = \frac{500}{62.5} = 8\text{ mL}$$

$$\text{RP: } \quad H \;:\; V \;::\; D \;:\; x$$
$$62.5\text{ mg} : 5\text{ mL} :: 100\text{ mg} : x\text{ mL}$$
$$62.5x = 500$$
$$x = 8\text{ mL of dicloxacillin}$$

2. Child's drug dosage:

a. 35 mcg × 10 kg = 350 mcg, or 0.35 mg

350 mcg = 0.350 mg

b. $$\text{BF: } \frac{D}{H}\times V = \frac{350\,\cancel{\text{mcg}}}{50\,\cancel{\text{mcg}}}\times 1\text{ mL} = 7\text{ mL loading dose}$$

or

$$\text{BF: } \frac{0.35\text{ mg}}{0.05\text{ mg}}\times 1\text{ mL} = 7\text{ mL loading dose}$$

3. Drug parameters:

20 mg × 12 kg = 240 mg/day
40 mg × 12 kg = 480 mg/day
Dosage order: 200 mg x 3 (q8h) = 600 mg/day
Dosage is not within safe drug parameters. Dose exceeds the drug parameters. Do *not* give the medication. Notify the health care provider.

4. a. 20 kg

b. First day: 10 mg × 20 kg = 200 mg

$$\text{BF: } \frac{D}{H}\times V = \frac{\overset{1}{\cancel{200}}\,\cancel{\text{mg}}}{\underset{1}{\cancel{200}}\,\cancel{\text{mg}}}\times 5\text{ mL} = 5\text{ mL}$$

or

$$\text{RP: } \quad H \;:\; V \;::\; D \;:\; x$$
$$200\text{ mg} : 5\text{ mL} :: 200\text{ mg} : x$$
$$200x = 1000$$
$$x = 5\text{ mL}$$

or

$$\text{DA: mL} = \frac{5\text{ mL} \times \overset{1}{\cancel{200}}\,\cancel{\text{mg}}}{\underset{1}{\cancel{200}}\,\cancel{\text{mg}} \times 1} = 5\text{ mL}$$

First day give 5 mL.

c. Second to fifth days (next 4 days):
5 mg × 20 kg = 100 mg
Give 2.5 mL/day. Same answer worked out by BF, RP, and DA.

5. a. Drug parameters: (28 lb ÷ 2.2 = 12.7 kg)

20 mg × 12.7 kg = 254 mg/day
40 mg × 12.7 kg = 508 mg/day
Dosage order: 100 mg × 3 (q8h) = 300 mg/day
Dosage is within safe drug parameters.

b. 4 mL of Augmentin

6. a. Drug parameters: 88 mg to 176 mg/day

b. Dose is within safe drug parameters.

c. $$\text{FE: } \frac{H}{V} = \frac{D}{x} \quad \frac{25\text{ mg}}{5\text{ mL}} = \frac{50\text{ mL}}{x} = 10\text{ mL per dose of Vibramycin}$$

$$\text{(cross-multiply) } 25x = 250$$
$$x = 10\text{ mL}$$

7. a. Child's weight 55 lbs ÷ 2.2 = 25 kg

b. 25,000 units × 25 = 625,000 units
90,000 units × 25 = 2,250,000 units
Child to receive 400,000 units × 4 (q6h) = 1,600,000 units per day
Yes, dose is within safe drug parameters

c. $$\text{BF: } \frac{D}{H}\times V = \frac{40}{20}\times 5 = \frac{200}{20} = 10\text{ mL of Veetids per dose}$$

8. Drug dosage: 2.5 mg × 1.2 m^2 = 3 mg

Administer 3 mg vinblastine.

2 PEDIATRIC INJECTABLES

1. a. Tobramycin parameter: 3 mg/kg/day ×10 kg = 30 mg/day in three divided doses
   Drug order: 10 mg × 3 (q8h) = 30 mg/day
   Dosage is within safe drug parameters.

   b. 10 mg = 1 mL/dose
   Child should receive 1 mL per dose.

2. a. Phenergan parameters:
   0.25 mg/kg/dose × 45 kg = 11.25 mg/dose
   0.50 mg/kg/dose × 45 kg = 22.5 mg/dose
   Drug order: Phenergan 20 mg IM per dose
   Dosage is within safe drug parameters.

   b. Phenergan 20 mg = 0.8 mL

3. a. Child weighs 44 lbs ÷ 2.2 = 20 kg

   b. 0.01 mg × 20 kg = 0.2 mg
   Yes, dosage is within safe drug parameters.

   c. RP:

$$\begin{array}{lllllll} \text{H} & : & \text{V} & :: & \text{D} & : & x \\ 0.4\text{ mg} & : & 1\text{ mL} & :: & 0.2\text{ mg} & : & x \end{array}$$

$$0.4x = 0.2$$

$$x = \tfrac{1}{2} \text{ or } 0.5\text{ mL of naloxone}$$

4. a. 200 mg × 4 (q6h) = 800 mg/day

   b. Dose per day is safe but not in therapeutic range. Notify health care provider.
   100 mg × 10 kg = 1000 mg
   300 mg × 10 kg = 3000 mg

   c. Add 1.8 mL diluent = 2 mL (500 g = 2 mL)

$$\text{RP: H : V :: D : } x$$

$$500 : 2 :: 200 : x$$

$$500x = 400$$

$$x = 0.8\text{ mL}$$

   Nafcillin 200 mg = 0.8 mL per dose

5. a. Preferred selection is AquaMEPHYTON 1 mg = 0.5 mL.

   b. $\frac{D}{H} \times V = \frac{0.5\,\cancel{mg}}{1.0\,\cancel{mg}} \times 0.5\text{ mL} = \frac{0.25}{1.0} = 0.25\text{ mL}$

   AquaMEPHYTON 1 mg = 0.5 mL

$$\frac{D}{H} \times V = \frac{0.5\,\cancel{mg}}{10\,\cancel{mg}} \times 1\text{ mL} = \frac{0.5}{10} = 0.05\text{ mL}$$

   For AquaMEPHYTON 1 mg = 0.5 mL. Give 0.25 mL. (Use a tuberculin syringe.)
   For AquaMEPHYTON 10 mg = 1 mL. Give 0.05 mL. (Use a tuberculin syringe; however, it would be difficult to give this small amount.)

6. a. 125 mg × 4 (q6h) = 500 mg

   b. Drug parameters: 22 kg. 25 mg/kg/day = 550 mg
   22 kg × 50 mg/kg/day = 1100 mg
   22 kg × 100 mg/kg/day = 2200 mg maximum (range: 550 to 2200 mg)
   Drug dose per day is below the suggested child's drug dose range. The nurse should contact the health care provider. The daily drug dose may need to be increased.

   c. Add 3.4 mL of diluent yielding 4 mL of drug solution.

   d. $\text{DA: mL} = \frac{4\text{ mL} \times \overset{1}{\cancel{125}}\,\cancel{mg}}{\underset{4}{\cancel{500}}\,\cancel{mg} \times 1} = 1\text{ mL}$

   Give 1 mL of cefazolin (Ancef) per dose.

7. Height and weight intersect at 0.82 m^2.
   Hydroxyzine parameter: 30 mg/m^2 × 0.82 m^2 = 24.6 mg, or 25 mg
   Drug order: hydroxyzine 50 mg IM
   Dosage is *not* within safe drug parameters. Dosage exceeds the drug parameters. Do not give the medication. Notify the health care provider.

8. Height and weight intersect at 1.38 m^2.
   Methotrexate parameters:
   25 mg/m^2/wk × 1.38 m^2 = 34.5 mg/wk
   75 mg/m^2/wk × 1.38 m^2 = 103.5 mg/wk
   Drug order: methotrexate 50 mg/wk IM
   Dosage is within safe drug parameters.
   (1) If methotrexate 25 mg/mL is used, give 2 mL (50 mg) **or** (2) If methotrexate 100 mg/mL is used, give 0.5 mL. Because of the amount of solution, it may be more desirable to give 0.5 mL of the 100 mg/mL solution.

UNIT IV

Nutrition and Electrolytes

Vitamins, minerals, and electrolytes are essential for cellular function. If significant lack of or imbalance of these chemical components occurs, replacement drug therapy is necessary, as is identifying and addressing any underlying causes for the lack or imbalance.

Both fat-soluble vitamins (vitamins A, D, E, and K) and water-soluble vitamins (vitamin B complex and C) are discussed in Chapter 15, Vitamin and Mineral Replacement. Iron is the primary mineral described in this chapter; other minerals discussed are copper, zinc, chromium, and selenium.

Body electrolytes are plentiful in extracellular and intracellular fluids and in the gastrointestinal mucosa. Potassium, sodium, calcium, and magnesium promote transmission and conduction of nerve impulses and contractility of muscles. Inadequate dietary intake and many disorders contribute to electrolyte imbalances. Chapter 16, Fluid and Electrolyte Replacement, discusses electrolyte replacement, and Chapter 17, Nutritional Support, discusses enteral and parenteral nutrition therapy.

CHAPTER 15

Vitamin and Mineral Replacement

evolve WEBSITE

- Key Points
- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Discuss the four justifications for the use of vitamin supplements.
- Differentiate between water-soluble and fat-soluble vitamins.
- Relate food sources and deficiency conditions associated with each vitamin.
- Explain the need for iron and foods that are high in iron content.
- Explain the uses for iron, copper, zinc, chromium, and selenium.
- Describe the nursing interventions, including patient teaching, related to vitamin and mineral uses.

minerals, p. 218
recommended dietary allowance, p. 212
tolerable upper intake level, p. 212
water-soluble vitamins, p. 215

Vitamins and minerals are needed in correct portions for normal body function. Overuse of vitamins and minerals, particularly fat-soluble vitamins and iron, may lead to vitamin or iron toxicity.

VITAMINS

Vitamins are organic chemicals that are necessary for normal metabolic functions and for tissue growth and healing. The body needs only a small amount of vitamins daily, which can be obtained through one's diet. A well-balanced diet has all of the vitamins and minerals needed for body functioning. The intake of vitamins should be increased by those experiencing periods of rapid body growth, those who are pregnant or breastfeeding, those with a debilitating illness, those with malabsorptive issues (e.g., Crohn's disease), and those with inadequate diets (e.g., alcoholics, some geriatric patients). Children who have poor nutrient intake or are malnourished may need vitamin replacement. People on "fad" or restrictive diets may have vitamin deficiencies, as may those who are unable to afford or do not select a wide variety of foods.

The sale of vitamins in the United States is a multibillion-dollar business. Numerous vitamins and herbal medications are available for specialized needs such as cholesterol, memory, menopause, and prostate. Before purchasing these agents, the patient should discuss with the health care provider the health value and use of multiple vitamins and herbal medications. People may take vitamins to relieve tiredness or to improve general overall health; these are inappropriate indications for vitamin therapy. Vitamin supplements are not necessary if the individual is healthy and consumes a well-balanced daily diet on a regular basis; however, patients may take vitamins as a sort of "insurance" to be sure they are getting what they need.

The Food and Nutrition Board of the National Academy of Sciences has established the Dietary Reference Intakes (DRI).

The DRI nutrient recommendations include the following:

1. **Adequate intake (AI)** is the amount determined to be sufficient in the absence of scientific information. The AI is based on data about the levels of vitamin intake that seem to maintain a healthy status.
2. **Estimated average requirement (EAR)** is the amount thought to provide a sufficient intake in one half of healthy persons in a defined group.
3. **Recommended dietary allowance (RDA)** is the amount thought to provide the needs of 98% of well children and adults of specific age group and gender. RDAs were developed to prevent deficiencies and may not be reflective of all groups, such as older adults.
4. **Tolerable upper intake level (UL)** is the maximum amount considered not likely to be a risk for healthy persons in a specified group. This is not a recommended level to take.

Vitamin deficiencies can cause cellular and organ dysfunction that may result in slow recovery from illness. Vitamin supplements are necessary for the vitamin deficiencies described in Table 15-1, but vitamins are frequently taken prophylactically rather than therapeutically.

With the goal of facilitating better nutrition, the United States Department of Agriculture (USDA) has developed Choose My Plate, part of a communications initiative based on their *2010 Dietary Guidelines for Americans.* Available at www.ChooseMyPlate.gov, MyPlate is an interactive tool that helps Americans to eat more healthfully (Figure 15-1), and the SuperTracker assists in the planning, analyzing, and tracking of nutrition and physical activity. This website offers a variety of features, including both consumer and professional information.

TABLE 15-1 JUSTIFICATION FOR VITAMIN SUPPLEMENTS

CATEGORIES	DEFICIENCIES
Malabsorption, diarrhea, infectious and inflammatory diseases (e.g., Crohn's disease, celiac disease)	
Inability to use vitamins	Liver disease (cirrhosis, hepatitis), renal disease, certain hereditary deficiencies
Increased vitamin losses	Fever from infectious process, hyperthyroidism, hemodialysis, cancer, starvation, crash diets
Increased vitamin requirements	Early childhood, pregnancy, debilitating disease (cancer, alcoholism), gastrointestinal surgery, special diets

The National Academy of Sciences Food and Nutrition Board publishes the U.S. RDA for daily dose requirements of each vitamin. The U.S Food and Drug Administration (FDA) requires that all vitamin products be labeled according to the amount of vitamin content and the proportion of the RDA provided by the vitamin product. Individuals should be encouraged to check the RDA listed on a vitamin container to determine whether the product provides the RDA dose requirements. The RDA may need to be modified for patients who are ill.

Megadoses of vitamins are available, advertised for specific health conditions; these high doses can be toxic. Patients should be advised to contact their health care provider before taking these products. Megadoses of fat-soluble vitamins (A, D, E, and K) may cause toxic effects. Megadoses of water-soluble vitamins are eliminated via the urine and thus are generally not toxic. Adverse reactions (kidney stones and nerve damage, respectively) have been reported from Vitamin C and Vitamin B_6. However, it is also claimed that B vitamins may positively influence metabolism in older adults.

Table 15-2 lists fat-soluble and water-soluble vitamins, their functions, suggested food sources, and selected deficiency conditions.

Fat-Soluble Vitamins

Vitamins fall into two general categories: fat-soluble and water-soluble. The **fat-soluble vitamins** are A, D, E, and K.

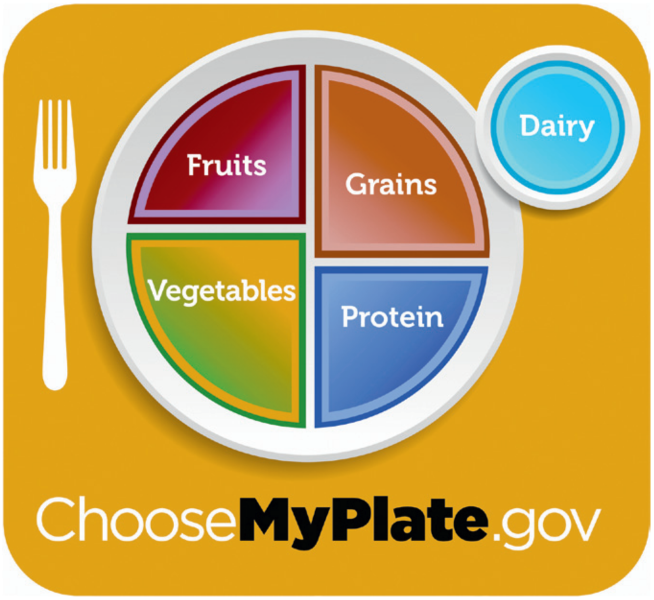

FIGURE 15–1 The U.S. Department of Agriculture's ChooseMyPlate.

TABLE 15-2 VITAMINS: FUNCTIONS, SUGGESTED FOOD SOURCES, AND SELECTED DEFICIENCY CONDITIONS

VITAMIN	FUNCTION	FOOD SOURCES	DEFICIENCY CONDITIONS
A (retinol)	Required for development and maintenance of healthy eyes, gums, teeth, skin, hair, and selected glands. Needed for fat metabolism.	Fortified milk, butter, eggs, leafy green and yellow vegetables and fruits. *Natural vitamin A, found only in animal sources: cod, halibut, shark, tuna	Dry skin, poor tooth development, night blindness
B_1 (thiamine)	Promotes use of sugars (energy). Required for good function of nervous system and heart.	Enriched breads and cereals, yeast, liver, pork, fish, milk, lentils, blackstrap molasses	Sensory disturbances, retarded growth, fatigue, anorexia
B_2 (riboflavin)	Promotes body's use of carbohydrates, proteins, and fats by releasing energy to cells. Required for tissue integrity.	Milk, enriched breads and cereals, liver, lean meat, eggs, almonds, wheat germ, soy, leafy green vegetables†	Visual defects such as blurred vision and photophobia; cheilosis; rash on nose; numbness of extremities
B_6 (pyridoxine)	Important in metabolism, protein synthesis, and formation of red blood cells.	Lean meat, leafy green vegetables, whole-grain cereals, yeast, bananas, salmon, soybeans, seeds, nuts, avocados, bananas, carrots	Neuritis, convulsions, dermatitis, anemia, lymphopenia
B_{12} (cobalamin)	Functions as a building block of nucleic acids and to form red blood cells. Facilitates functioning of nervous system.	Liver, kidney, fish, milk, eggs, chicken, turkey	Gastrointestinal disorders, poor growth, anemias
folic acid (folvite)	Helps in formation of genetic materials and proteins for the cell nucleus. Assists with intestinal functioning. Prevents selected anemias.	Leafy green vegetables, yellow fruits and vegetables, yeast, organ meats, black-eyed peas, lentils	Decreased white blood cell count and clotting factors, anemias, intestinal disturbances, depression
Pantothenic acid	Promotes body's use of carbohydrates, fats, and proteins. Essential for formation of specific hormones and nerve-regulating substances.	Eggs, leafy green vegetables, nuts, liver, kidney, skim milk, seeds, nuts, wheat germ, salmon	Natural deficiency unknown in humans
Niacin	In all body tissues. Necessary for energy-producing reactions. Assists nervous system.	Eggs, meat, liver, beans, peas, enriched bread and cereals	Retarded growth, pellagra, headache, memory loss, anorexia, insomnia
Biotin	Synthesis of fatty acids and energy production from glucose. Required by body chemical systems.	Eggs, milk, leafy green vegetables, liver, kidney	Natural deficiency unknown in humans
C (ascorbic acid)	Helps tissue repair and growth. Required in formation of collagen.	Citrus fruits, cantaloupe, tomatoes, leafy green vegetables, sweet red peppers, potatoes, strawberries, kiwi	Poor wound healing, bleeding gums, scurvy, predisposition to infection
D (calciferol)	Promotes use of phosphorus and calcium. Important for strong teeth and bones.	Vitamin D–fortified milk, egg yolk, tuna, salmon, liver	Rickets in children; osteomalacia in adults
E (alpha-tocopherol)	Protects fatty acids and promotes formation and functioning of red blood cells, muscle, and other tissues.	Whole-grain cereals, wheat germ, vegetable oils, lettuce, sunflower seeds, milk, eggs, meat, avocados, asparagus	Breakdown of red blood cells
K	Essential for blood clotting.	Leafy green vegetables, liver, cheese, egg yolk, vegetable oil, tomatoes	Increased clotting time, leading to increased bleeding and hemorrhage

*Yellow fruits and vegetables include apricots, cantaloupe, carrots, rutabaga, pumpkin, squash, and sweet potatoes.
†Leafy green vegetables include brussels sprouts, chard, broccoli, kale, spinach, and turnip and mustard greens.

They are metabolized slowly; can be stored in fatty tissue, liver, and muscle in significant amounts; and are excreted in the urine at a slow rate. Vitamins A and D are toxic if taken in excessive amounts over time. Current research shows that vitamin D toxicity is quite rare, and its symptoms are fairly nonspecific. Given that many people are found to be vitamin D deficient, it is not uncommon to see high-dose vitamin D therapy (e.g., 50,000 units/week). Historically, vitamins E and K were thought to be less toxic than vitamins A and D. Vitamin E was once considered a "wonder" drug, supposedly beneficial for the heart and brain, but it was later determined that vitamin E was an independent risk factor for the development of heart failure.

Foods rich in vitamin A, vitamin D, vitamin E, or vitamin K are shown in Table 15-2.

Vitamin A

Vitamin A is essential for bone growth and the maintenance of epithelial tissues, skin, eyes, and hair. It has been used for the treatment of skin disorders such as acne; however, excess doses can be toxic. During pregnancy, excessive amounts of vitamin A (>6000 international units) might have a teratogenic effect (birth defects) on the fetus. Prototype Drug Chart 15-1 describes the pharmacologic data on vitamin A. IM administration is used only in acutely ill patients or patients refractory to the oral route, such as those with gastrointestinal (GI) malabsorption syndrome.

Pharmacokinetics When a person is deficient in vitamin A, the vitamin is absorbed faster than when there is no deficiency or intestinal obstruction. A portion of vitamin A is stored in the liver, and this function can be inhibited with liver disease. Massive doses of vitamin A may cause hypervitaminosis A, symptoms of which are hair loss, peeling skin, anorexia, abdominal pain, lethargy, nausea, and vomiting.

The UL for vitamin A is 3000 mcg daily (3000 mcg daily = 10,000 international units). Excess use of vitamin A should be avoided unless warranted because this vitamin is stored in the liver, kidneys, and fat, and it is slowly excreted from the body. Excess vitamin A is stored in the liver for up to 2 years. Vitamin A toxicity affects multiple organs, especially the liver. To prevent the occurrence of vitamin A toxicity, the dose for healthy patients should not be greater than 7500 international units.

Mineral oil, cholestyramine, alcohol, and antilipemic drugs decrease the absorption of vitamin A. Vitamin A is excreted through the kidneys and feces.

Pharmacodynamics Vitamin A is necessary for many biochemical processes. It aids in the formation of the visual pigment needed for night vision. This vitamin is needed in bone growth and development, and it promotes the integrity of the mucosal and epithelial tissues. An early sign of vitamin A deficiency (hypovitaminosis A) is night blindness. This may progress to dryness and ulceration of the cornea and to blindness.

Vitamin A taken orally begins to take effect in 1 to 2 hours and peaks in 4 to 5 hours. Its duration of action is unknown. Because vitamin A is stored in the liver, the vitamin may be available to the body for days, weeks, or months.

Vitamin D

Vitamin D has a major role in regulating calcium and phosphorus metabolism and is needed for calcium absorption

PROTOTYPE DRUG CHART 15-1

Vitamin A

Drug Class Fat-soluble vitamin Trade Names: Acon, Aquasol A, Del-VI-A Pregnancy Category: A (X if doses are above RDA)	**Dosage** Severe deficiency: A and C >8 y: PO: 100,000-500,000 international units/d × 3 d; then 50,000 international units/d × 14 d (based on severity) C: Infant to 8 y: IM: 5000-15,000 international units/d × 10 d Maintenance: C: 4-8 y: IM: 5000-15,000 international units/d × 2 mo C: <4 y 10,000 international units/d × 2 mo
Contraindications Hypervitaminosis A, pregnancy (massive doses)	**Drug-Lab-Food Interactions** Drug: Mineral oil may decrease absorption of vitamin A, cholestyramine Lab: May increase BUN, calcium, cholesterol, triglycerides; may lower erythrocyte, leukocyte counts Food: None known
Pharmacokinetics Absorption: PO: 1 h Distribution: PB: UK Metabolism: t½: weeks-months Excretion: Urine	**Pharmacodynamics** PO: Onset: 1-2 h Peak: 4-5 h Duration: UK
Therapeutic Effects/Uses To treat vitamin A deficiency (biliary tract or pancreatic disease, colitis, cirrhosis, celiac disease, sprue), prevent night blindness, treat skin disorders, promote bone development Mode of Action: Essential for growth, bone and teeth development, vision, integrity of skin and mucous membranes, and reproduction	
Side Effects Headache, fatigue, drowsiness, irritability, anorexia, vomiting, diarrhea, dry skin, visual changes	**Adverse Reactions** Evident only with toxicity: leukopenia, aplastic anemia, papilledema, increased intracranial pressure, hypervitaminosis A, bulging fontanelles in infants, jaundice

A, Adult; *C,* child; *d,* day; *h,* hour; *IM,* intramuscular; *PB,* protein binding; *PO,* by mouth; *RDA,* recommended daily allowance; *t½,* half life; *UK,* unknown; *y,* year; *<,* less than; *>,* greater than.

from the intestines. Dietary vitamin D is absorbed in the small intestine and requires bile salts for absorption. There are two compounds of vitamin D: vitamin D_2, ergocalciferol (a synthetic fortified vitamin D), and vitamin D_3, cholecalciferol (a natural form of vitamin D influenced by ultraviolet sunlight through the skin). Over-the-counter vitamin D supplements usually contain vitamin D_3. Once absorbed, vitamin D is converted to calcifediol (also known as *25-hydroxycholecalciferol*) in the liver. Calcifediol is then converted to an active form, calcitriol, in the kidneys. Studies have suggested that vitamin D, taken with calcium, can reduce the incidence of fractures.

Calcitriol, the active form of vitamin D, functions as a hormone and, with parathyroid hormone (PTH) and calcitonin, regulates calcium and phosphorus metabolism. Calcitriol and PTH stimulate bone reabsorption of calcium and phosphorus. Excretion of vitamin D is primarily in bile; only a small amount is excreted in the urine. If serum calcium levels are low, more vitamin D is activated; when serum calcium levels are normal, activation of vitamin D is decreased.

Excess vitamin D ingestion (>40,000 international units) results in hypervitaminosis D and may cause hypercalcemia (an elevated serum calcium level). Anorexia, nausea, and vomiting are early symptoms of vitamin D toxicity.

Vitamin E

Vitamin E has antioxidant properties that protect cellular components from being oxidized and red blood cells from hemolysis. Vitamin E depends on bile salts, pancreatic secretion, and fat for its absorption. Vitamin E is stored in all tissues, especially the liver, muscle, and fatty tissue. About 75% of vitamin E is excreted in bile.

It has been reported that taking 400 to 800 international units of vitamin E per day reduces the number of nonfatal myocardial infarctions (MIs). Also, it has been stated that taking 200 international units per day for several years can reduce the risk of coronary artery disease (CAD), but the use of vitamin E for CAD is being questioned. However, many still state that this vitamin protects the heart and arteries and aids in the prevention of macular degeneration because of its antioxidant effects (i.e., it inhibits the oxidation of other compounds by blocking a group of harmful chemicals called **free radicals**). Many patients with Alzheimer's or Parkinson's disease take supplemental vitamin E for its antioxidant effects.

SAFETY: Preventing Medication Errors

Do not confuse…

- **Aquasol A** or **Aquasol E** with **Anusol,** an antiinflammatory generally used to treat hemorrhoids

Side effects of large doses of vitamin E may include fatigue, weakness, nausea, GI upset, headache, and breast tenderness. Vitamin E may prolong the prothrombin time (PT). Patients taking warfarin should have their PT monitored closely. Iron and vitamin E should not be taken together because iron can interfere with the body's absorption and use of vitamin E.

Vitamin K

Vitamin K occurs in four forms. Vitamin K_1 (phytonadione) is the most active form; vitamin K_2 (menaquinone) is synthesized by intestinal flora; and vitamin K_3 (menadione) and vitamin K_4 (menadiol) have been produced synthetically. Vitamin K_2 is not commercially available. Vitamins K_1 and K_2 are absorbed in the presence of bile salts. Vitamins K_3 and K_4 do not need bile salts for absorption. After vitamin K is absorbed, it is stored primarily in the liver and in other tissues. Half of vitamin K comes from the intestinal flora, and the remaining portion comes from one's diet.

Vitamin K is needed for synthesis of prothrombin and the clotting factors VII, IX, and X. For oral anticoagulant overdose, vitamin K_1 (phytonadione) is the only vitamin K form available for therapeutic use and is most effective in preventing hemorrhage. The commercial drugs available for vitamin K_1 are called Mephyton and AquaMEPHYTON. Vitamin K is used for two reasons: (1) as an antidote for oral anticoagulant overdose and (2) to prevent and treat the hypoprothrombinemia of vitamin K deficiency. Spontaneous hemorrhage may occur with vitamin K deficiency due to lack of bile salts and malabsorption syndromes that interfere with vitamin K uptake (e.g., celiac disease). Newborns are vitamin K deficient; thus, a single dose of phytonadione is recommended immediately after delivery. This practice is common in the United States but controversial in other countries. This can elevate the bilirubin level and cause hyperbilirubinemia with a risk of kernicterus. There are oral and parenteral forms of phytonadione; IV administration is dangerous and may cause death.

Water-Soluble Vitamins

Water-soluble vitamins are the B-complex vitamins and vitamin C. This group of vitamins is not usually toxic unless taken in extremely excessive amounts. Water-soluble vitamins are not stored by the body, so consistent, steady supplementation is required. Water-soluble vitamins are readily excreted in the urine. Protein binding of water-soluble vitamins is minimal. Foods that are high in vitamin B are grains, cereal, bread, and meats. There are reports that B vitamins may promote a sense of well-being and increased energy as well as decreased anger, tension, and irritability. Citrus fruits and green vegetables are high in vitamin C. If the fruits and vegetables are cut or cooked, a large amount of vitamin C is lost.

Vitamin B Complex

Vitamin B_1 (thiamine), vitamin B_2 (riboflavin), vitamin B_3 (nicotinic acid, or niacin), and vitamin B_6 (pyridoxine) are four of the vitamin B-complex members. This B-complex group is water-soluble. It is a common group of vitamins administered in the clinical setting, especially to patients with alcoholism.

Thiamine deficiency can lead to the polyneuritis and cardiac pathology seen in beriberi or to Wernicke's encephalopathy that progresses to Korsakoff's syndrome, conditions most commonly associated with alcohol abuse. Wernicke-Korsakoff syndrome is a significant central nervous system disorder characterized by confusion, nystagmus, diplopia, ataxia, and loss of recent memory. If not treated, it may cause irreversible brain damage. IV administration of thiamine is recommended for treatment of Wernicke-Korsakoff syndrome. Thiamine must be given before giving any glucose to avoid aggravation of symptoms.

Riboflavin may be given to manage dermatologic problems such as scaly dermatitis, cracked corners of the mouth, and inflammation of the skin and tongue. To treat migraine headache, riboflavin is given in larger doses than for dermatologic concerns.

Niacin is given to alleviate pellagra and hyperlipidemia, for which large doses are required. Chapter 46 offers a discussion of niacin use to reduce cholesterol levels. However, large doses may cause GI irritation and vasodilation, resulting in a flushing sensation.

Pyridoxine is administered to correct vitamin B_6 deficiency. It may also help alleviate the symptoms of neuritis caused by isoniazid (INH) therapy for tuberculosis. Vitamin B_6 is an essential building block of nucleic acids, red blood cell formation, and synthesis of hemoglobin. Pyridoxine is used to treat vitamin B_6 deficiency caused by lack of adequate diet, inborn errors of metabolism, or drug-induced deficiencies secondary to INH, penicillamine, or cyclosporine (or hydralazine) therapy. It is also used to treat neonates with seizures refractory to traditional therapy. Vitamin B_6 deficiencies may occur in alcoholics along with deficiencies of other B-complex vitamins. Patients with diabetes or alcoholism may benefit from daily supplementation. Pyridoxine is readily absorbed in the jejunum and stored in the liver, muscle, and brain. It is metabolized in the liver and excreted in the urine.

SAFETY: Preventing Medication Errors

Do not confuse…

pyridoxine (vitamin B_6) with

- **paroxetine** (Paxil), an antidepressant
- **pralidoxime**, an antidote used to treat poisoning with organophosphate pesticides and chemicals that have anticholinesterase activity
- **phenazopyridine** (Pyridium), a urinary analgesic

Vitamin C

Vitamin C (ascorbic acid) is absorbed from the small intestine. Vitamin C aids in the absorption of iron and in the conversion of folic acid. Vitamin C is not stored in the body and is excreted readily in the urine. A high serum vitamin C level that results from excessive dosing of vitamin C is excreted by the kidneys unchanged.

The recommended daily dose of vitamin C for an adult is 50 to 100 mg/day. Some individuals take greater amounts to treat upper respiratory infections, cancer, or hypercholesterolemia. Massive doses of vitamin C can cause diarrhea and GI upset. Prototype Drug Chart 15-2 details pharmacologic data on vitamin C.

Pharmacokinetics Vitamin C is absorbed readily through the GI tract and is distributed throughout the body fluids. The kidneys completely excrete vitamin C, mostly unchanged.

Pharmacodynamics Vitamin C is needed for carbohydrate metabolism and protein and lipid synthesis. Collagen synthesis also requires vitamin C for capillary endothelium, connective tissue and tissue repair, and osteoid tissue of the bone. Large doses of vitamin C (>5 to 10 g) may decrease the effect of oral anticoagulants. Smoking decreases serum vitamin C levels. Vitamin C (in doses >500 mg) aids iron absorption.

The use of **megavitamin therapy,** massive doses of vitamins, is questionable at best. Megadoses of vitamins can cause toxicity and might result in minimal desired effect. Most authorities believe that vitamin C does not cure or prevent the common cold; rather, they believe that vitamin C has a placebo effect. Moreover, megadoses of vitamin C taken with aspirin or sulfonamides may cause crystal formation in the urine (crystalluria). Excessive doses of vitamin C can cause a false-negative occult (blood) stool result and false-positive sugar result in the urine when tested by the Clinitest method. If large doses of megavitamins are to be discontinued, a gradual reduction of dosage is necessary to avoid vitamin deficiency. Note: There is danger of children overdosing on adult or children's multivitamins containing iron.

Folic Acid (Folate)

Folic acid is absorbed from the small intestine, and the active form of folic acid (folate) is circulated to all tissues. One third of folate is stored in the liver, and the rest is stored in tissues. Eighty percent of folate is excreted in bile and 20% in urine.

Folic acid is essential for body growth. It is needed for deoxyribonucleic acid (DNA) synthesis, and without folic acid there is a disruption in cellular division. Chronic alcoholism, poor nutritional intake, malabsorption syndromes, pregnancy, and drugs that cause inadequate absorption (phenytoin, barbiturates) or folic acid antagonists (methotrexate, triamterene, trimethoprim) are causes of folic acid deficiencies. Symptoms of folic acid deficiencies include anorexia, nausea, stomatitis, diarrhea, fatigue, alopecia, and blood dyscrasias (megaloblastic anemia, leukopenia, thrombocytopenia). These symptoms are usually not noted until 2 to 4 months after folic acid storage is depleted.

Folic acid deficiency during the first trimester of pregnancy can affect the development of the central nervous system (CNS) of the fetus. This may cause neural tube defects (NTDs) such as spina bifida (defective closure of the bony structure of the spinal cord) or anencephaly (lack of brain mass formation). The U.S. Public Health Services recommends that all women who may become pregnant consume 400 mcg of supplemental folic acid each day—in addition to the folate they get with food. Synthetic folate is more stable than food; bioavailability is >85% and <59%, respectively. There is some evidence that 400 to 800 mcg (0.4 to 0.8 mg) of folic acid per day can decrease the incidence of coronary artery disease (CAD). It is thought that folic acid decreases the amino acid homocysteine in the blood, which may contribute to heart disease. Folic acid may also offer some protection from colorectal cancer.

PROTOTYPE DRUG CHART 15-2

Vitamin C

Drug Class
Water-soluble vitamin
Trade Names: Ascorbicap, Cecon, Cevalin, Solucap C, 🍁 Apo-C, Ce-Vi-Sol, Redoxon
Pregnancy Category: A (C if used in doses above RDA)

Dosage
Prophylactic:
A: PO: 45-60 mg/d
C: PO: 20-50 mg/d
Severe deficit: Scurvy
A: PO: IM: IV: 150-250 mg/twice daily (larger doses have shown no additional benefit.
C: PO: IM: IV: 100-300 mg/d × 2 wk; then 35 mg or more daily
Chronic disease/fracture/wound healing:
A: IM/IV/PO: 200-500 mg/d for 1-2 months
C: IM/IV/PO: 100-200 mg/d for 1-2 months
Pregnancy and lactation:
A: PO: 160-80 mg/d

Contraindications
Caution: Renal calculi, gout, anemia: sickle cell, sideroblastic, thalassemia

Drug-Lab-Food Interactions
Decrease ascorbic acid uptake taken with salicylates; may decrease effect of oral anticoagulants; may decrease elimination of aspirins
Lab: May decrease bilirubin, urinary pH; may increase uric acid, uric oxalate
Food: None known

Pharmacokinetics
Absorption: PO: quickly
Distribution: PB: 25%
Metabolism: t½: UK
Excretion: In the urine; unchanged with high doses

Pharmacodynamics
PO:
Onset: >2 d
Peak: UK
Duration: UK

Therapeutic Effects/Uses
To prevent and treat vitamin C deficiency (scurvy); to increase wound healing; for burns. Preserves integrity of blood vessels.
Mode of Action: A water-soluble vitamin, essential for collagen formation and tissue repair (bones, skin, blood vessels); synthesis of lipids, protein, carnithine

Side Effects
Oral: Nausea, vomiting, diarrhea; heartburn; headache
Parenteral: Flushing, headache, dizziness, soreness at injection site

Adverse Reactions
Kidney stones, crystalluria, hyperuricemia. Hemolytic anemia with patients with G6PD deficiency.
Life-threatening: Sickle cell crisis, deep vein thrombosis

A, Adult; *C,* child; *d,* day; *IM,* intramuscular; *IV,* intravenous; *PB,* protein binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *>,* greater than; 🍁, Canadian drug name.

SAFETY: Preventing Medication Errors

Do not confuse…

- **Folvite** with **Florvite,** a fluoride supplement added to the water supply.

Excessive doses of folic acid may mask signs of vitamin B_{12} deficiency, which is a risk in older adults. Patients taking phenytoin (Dilantin) to control seizures should be cautious about taking folic acid. This vitamin can lower the serum phenytoin level, which could increase the risk of seizures. The phenytoin dose would need to be adjusted in such patients. This is a complex interaction that is not fully understood, but it is thought that 1 mg or less per day of folic acid is safe in patients with controlled epilepsy.

Vitamin B_{12}

Vitamin B_{12}, like folic acid, is essential for DNA synthesis. Vitamin B_{12} aids in the conversion of folic acid to its active form. With active folic acid, vitamin B_{12} promotes cellular division. It is also needed for normal hematopoiesis (development of red blood cells in bone marrow) and to maintain nervous system integrity, especially the myelin.

The gastric parietal cells produce an intrinsic factor that is necessary for the absorption of vitamin B_{12} through the intestinal wall. Without the intrinsic factor, little or no vitamin B_{12} is absorbed. After absorption, vitamin B_{12} binds to the protein transcobalamin II and is transferred to the tissues. Most vitamin B_{12} is stored in the liver. Vitamin B_{12} is slowly excreted, and it can take 2 to 3 years for stored vitamin B_{12} to be depleted and a deficit noticed.

Vitamin B_{12} deficiency is uncommon unless there is a disturbance of the intrinsic factor and intestinal absorption. Pernicious anemia (lack of the intrinsic factor) is the major cause of vitamin B_{12} deficiency. Vitamin B_{12} deficiency can also develop in strict vegetarians who do not consume meat, fish, or dairy products. Other possible causes of vitamin B_{12}

deficiency include malabsorption syndromes (cancer, celiac disease, certain drugs), gastrectomy, Crohn's disease, and liver and kidney diseases. B_{12} deficiency is commonly seen with metformin and proton pump inhibitors (e.g., omeprazole). Symptoms may include numbness and tingling in the lower extremities, weakness, fatigue, anorexia, loss of taste, diarrhea, memory loss, mood changes, dementia, psychosis, megaloblastic anemia with macrocytes (overenlarged erythrocytes [red blood cells]) in the blood, and megaloblasts (overenlarged erythroblasts) in the bone marrow.

To correct vitamin B_{12} deficiency, cyanocobalamin in crystalline form can be given intramuscularly for severe deficits. It cannot be given intravenously because of possible hypersensitive reactions. Cyanocobalamin can be given orally and is commonly found in multivitamin preparations. It can also be given as a subcutaneous injection.

MINERALS

Various **minerals**, such as iron, copper, zinc, chromium, and selenium, are needed for body function.

Iron

Iron (ferrous sulfate, gluconate, or fumarate) is vital for hemoglobin regeneration. Sixty percent of the iron in the body is found in hemoglobin. One of the causes of anemia is iron deficiency. A normal diet contains 5 to 20 mg of iron per day. Foods rich in iron include liver, lean meats, egg yolks, dried beans, green vegetables (e.g., spinach), and fruit. Food and antacids slow the absorption of iron, and vitamin C increases iron absorption.

During pregnancy, an increased amount of iron is needed, but during the first trimester of pregnancy megadoses of iron are contraindicated because of its possible teratogenic effect on the fetus. Larger doses of iron are required during the second and third trimesters of pregnancy.

The dose of iron for infants and children 6 months to 2 years of age is 1.5 mg/kg of body weight. For the adult, 50 mg/day is needed for hemoglobin regeneration. The ferrous sulfate tablet is 325 mg, of which 65 mg is elemental iron. Therefore one tablet of ferrous sulfate is sufficient as a daily iron dose when indicated. Prototype Drug Chart 15-3 describes the pharmacologic data on iron.

Pharmacokinetics Iron is absorbed by the intestines and enters the plasma as heme, or it may be stored as ferritin. Although food decreases absorption by 25% to 50%, it may be necessary to take iron preparations with food to avoid GI discomfort. Vitamin C at doses > 500 mg may slightly increase iron absorption, whereas tetracycline, quinolone antibiotics (ciprofloxacin, levoflaxicin, etc.), and antacids can decrease absorption (Herbal Alert 15-1).

HERBAL ALERT 15-1

Iron

Chamomile, feverfew, peppermint, and St. John's wort interfere with the absorption of iron and other minerals.

Nursing Process
Patient-Centered Collaborative Care

Vitamins

Assessment

- Check patient for vitamin deficiency before start of therapy and regularly thereafter. Explore such areas as inadequate nutrient intake, debilitating disease, and GI disorders.
- Obtain 24- and 48-hour diet history analysis.

Nursing Diagnoses

- Imbalanced nutrition related to inadequate intake of food sources of vitamins
- Deficient knowledge related to food sources of vitamins
- Readiness for enhanced decision making related to food choices and vitamin supplementation

Planning

- Patient will eat a well-balanced diet.
- Patient with vitamin deficiency will take vitamin supplements as prescribed.
- Patient will demonstrate knowledge of food sources of vitamins.

Nursing Interventions

- Administer vitamins with food to promote absorption.
- Store drug in light-resistant container.
- Use the supplied calibrated dropper for accurate dosing when administering vitamins in drop form. Solution may be administered mixed with food or dropped into the mouth.
- Administer IM primarily for patients unable to take by PO route (e.g., GI malabsorption syndrome).
- Recognize need for vitamin E supplements for infants receiving vitamin A to avoid risk of hemolytic anemia.
- Monitor for vitamin A therapeutic serum levels (80 to 300 international units/mL).

Patient Teaching

General

- Advise patient to take prescribed amount of drug.
- Counsel patients to read vitamin labels to determine which vitamin is most appropriate for them.
- Advise patient to consult with health care provider/pharmacist regarding interactions with prescription and OTC medications.
- Discourage patient from taking megavitamins over a long period unless these are prescribed for a specific purpose by health care provider. To discontinue long-term megavitamin therapy, a gradual decrease in vitamin intake is advised to avoid vitamin deficiency.
- Inform patient that missing vitamins for 1 or 2 days is not a cause for concern, because deficiencies do not occur for some time.

PROTOTYPE DRUG CHART 15-3

Iron

Drug Class Mineral for antianemia Trade Names: ferrous sulfate (Feosol, Fer-Iron), ferrous gluconate (Fergon, Fertinic), ferrous fumarate (Feostat, Fumerin) Pregnancy Category: A	**Dosage** Sulfate: A: PO: 250-325 mg t.i.d. C: 6-12 y: PO 3/kg elemental iron per day in 1-2 divided doses Pregnancy: PO: 300-600 mg/d Gluconate: A: PO: 320-640 mg t.i.d./q.i.d. C: 6-12 y: PO: 3 mg/kg elemental iron per day C: < 6 y: PO: 100-300 mg/d
Contraindications Hemolytic anemia, hemosiderosis, peptic ulcer, ulcerative colitis Caution: Bronchial asthma, iron hypersensitivity	**Drug-Lab-Food Interactions** Increased effect of iron with vitamin C; decreased effect of tetracycline, antacids, penicillamine Lab: May increase bilirubin; may decrease calcium Food: None known
Pharmacokinetics Absorption: PO: 10%-30% intestines Distribution: PB: UK Metabolism: t½: 6 h Excretion: Urine, feces, sweat	**Pharmacodynamics** PO: Onset: 4 d Peak: 7-14 d Duration: 3-4 months
Therapeutic Effects/Uses To prevent and treat iron-deficiency anemia Mode of Action: Enables RBC development and oxygen transport via hemoglobin	
Side Effects Nausea, vomiting, diarrhea, constipation, epigastric pain; elixir may stain teeth	**Adverse Reactions** May aggravate existing GI conditions Pallor, drowsiness Life-threatening: Iron poisoning (mostly in children) and may result in cardiovascular collapse, metabolic acidosis Toxicity: Nausea, vomiting, diarrhea, (green then tarry stools), hematemesis, pallor, cyanosis, shock, coma

A, Adult; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *PB,* protein binding; *PO,* by mouth; *t.i.d.,* three times a day; *q.i.d.,* four times a day; *RBC,* red blood cell; *t½,* half-life; *UK,* unknown; *y,* year; ≥, greater than or equal to.

- Advise patient to check expiration dates on vitamin containers before purchasing them. Potency of the vitamin is reduced after the expiration date.
- Counsel patient to avoid taking mineral oil with vitamin A on a regular basis, because it interferes with absorption of the vitamin; mineral oil also interferes with vitamin K absorption. If needed, take mineral oil at bedtime.
- Explain to patient that there is no scientific evidence that megadoses of vitamin C will cure a cold.
- Alert patient not to take megadoses of vitamin C with aspirin or sulfonamides because crystals may form in the kidneys and urine.
- Alert patient to avoid excessive intake of alcoholic beverages. Alcohol can cause vitamin B-complex deficiencies.

Diet

- Advise patient to eat a well-balanced diet. Vitamin supplements are not necessary if the person is healthy and receives proper nutrition on a regular basis.
- Educate patient about foods rich in vitamin A, including milk, butter, eggs, and leafy green and yellow vegetables. Foods rich in other vitamins are listed in Table 15-2.

Side Effects

- Advise patient that nausea, vomiting, headache, loss of hair, and cracked lips (symptoms of hypervitaminosis A) should be reported to the health care provider. Early symptoms of hypervitaminosis D are anorexia, nausea, and vomiting.

Cultural Considerations

- Food and food choices have strong cultural roots. Determine the patient's preferred and culturally meaningful foods, and incorporate them into food and supplement plan.
- Use interpreters as appropriate.
- G-6-PD deficiency is common among people of Arab or Chinese heritage.

Evaluation

- Evaluate patient's understanding of the purpose of vitamins and their correct use.
- Evaluate effectiveness of patient's diet for the inclusion of appropriate amounts and types of food. Have patient periodically keep a diet chart for a complete week to determine typical nutrition.
- Determine whether patient with malnutrition is receiving appropriate vitamin therapy.

Pharmacodynamics Iron replacement is given primarily to correct or control iron-deficiency anemia, which is diagnosed by a laboratory blood smear. Positive findings for this anemia are microcytic (small), hypochromic (pale) erythrocytes (red blood cells [RBCs]). Clinical signs and symptoms include fatigue, weakness, shortness of breath, pallor, and, in cases of severe anemia, increased GI bleeding. The dosage of ferrous sulfate for prophylactic use is 300 to 325 mg/day; for therapeutic use, the dosage is 600 to 1200 mg/day in divided doses.

The onset of action for iron therapy takes days, and its peak action does not occur for days or weeks; therefore the patient's symptoms are slow to improve. Increased hemoglobin and hematocrit levels occur within 3 to 7 days.

Iron toxicity is a serious cause of poisoning in children. As few as 10 tablets of ferrous sulfate (3 g) taken at one time can be fatal within 12 to 48 hours. Hemorrhage due to the ulcerogenic effects of unbound iron leads to shock. Parents should be cautioned against leaving iron tablets that look like candy (e.g., M&Ms) within a child's reach. Most iron products are distributed in bubble packs. There is also danger of children overdosing on adult or children's multivitamins containing iron.

Copper

Copper is needed for the formation of RBCs and connective tissues. Copper is a cofactor of many enzymes, and its function is in the production of the neurotransmitters norepinephrine and dopamine. Excess serum copper levels may be associated with Wilson's disease, which is an inborn error of metabolism that allows for large amounts of copper to accumulate in the liver, brain, cornea (brown or green Kayser-Fleischer rings), or kidneys.

A prolonged copper deficiency may result in anemia, which is not corrected by taking iron supplements. Abnormal blood and skin changes caused by a copper deficiency include a decrease in white blood cell count, glucose intolerance, and a decrease in skin and hair pigmentation. Mental retardation may also occur in the young.

The RDA for copper is 1.5 to 3 mg/day. Most adults consume about 1 mg/day. Foods rich in copper are shellfish (crab, oysters), liver, nuts, seeds (sunflower, sesame), legumes, and cocoa.

Zinc

Zinc is important to many enzymatic reactions and is essential for normal growth and tissue repair, wound healing, and taste and smell. The use of zinc has greatly increased in the past few years; some believe zinc can alleviate symptoms of the common cold and shorten its duration. Individuals may take as much as 200 mg/day. The adult RDA is 12 to 19 mg/day. Foods rich in zinc include beef, lamb, eggs, and leafy and root vegetables.

Large doses, more than 150 mg, may cause a copper deficiency, a decrease in high-density lipoprotein (HDL) cholesterol ("good" cholesterol), and a weakened immune response. Zinc can inhibit tetracycline absorption. Patients taking zinc and an antibiotic should not take them together; zinc should be taken at least 2 hours after taking an antibiotic. Patients on long-term parenteral nutrition are at risk for zinc deficiency. Serum zinc levels may not correlate with degree of deficiency.

Chromium

Chromium is said to be helpful in the control of type 2 diabetes (non–insulin-dependent diabetes). It is thought that this mineral helps to normalize blood glucose by increasing the effects of insulin on the cells. If a patient is taking large doses of chromium and an oral hypoglycemic agent or insulin, the glucose level should be monitored closely for a hypoglycemic reaction. The dose of an oral hypoglycemic drug or insulin may need to be decreased. Some patients with an impaired glucose tolerance or patients who do not have diabetes may benefit by taking chromium. In addition, chromium claims to promote weight loss and muscle building. Multivitamin and mineral preparations contain chloride salt of chromium.

There is no RDA for chromium; however, 50 to 200 mcg/day is considered within the normal range for adults and children older than 6 years of age. Foods rich in chromium include meats, whole-grain cereals, and brewer's yeast.

Selenium

Selenium acts as a cofactor for an antioxidant enzyme that protects protein and nucleic acids from oxidative damage. Selenium works with vitamin E. It is thought that selenium has an anticarcinogenic effect, and doses lower than 200 mcg may reduce the risk of lung, prostate, and colorectal cancer. Excess doses of more than 200 mcg might cause weakness, hair loss, dermatitis, nausea, diarrhea, and abdominal pain. Also, there may be a garlic-like odor from the skin and breath.

The RDA for selenium is 40 to 75 mcg (lower dose for women, higher dose for men). Foods rich in selenium include meats (especially liver), seafood, eggs, and dairy products.

Nursing Process
Patient-Centered Collaborative Care

Antianemia, Mineral: Iron

Assessment

- Obtain a drug history of current drugs and herbs patient is taking.
- Obtain a history of anemia or health problems that may lead to anemia.
- Assess patient for signs and symptoms of iron-deficiency anemia, such as fatigue, malaise, pallor, shortness of breath, tachycardia, and cardiac dysrhythmia.
- Assess the patient's RBC count, hemoglobin, hematocrit, iron level, and reticulocyte count before the start of and throughout therapy.

Nursing Diagnoses

- Imbalanced nutrition related to inadequate intake of food sources of iron
- Deficient knowledge of food sources of iron
- Readiness for enhanced decision making related to food choices and vitamin/mineral supplementation

Planning

- Patient will name at least six foods high in iron content.
- Patient will consume foods rich in iron.
- Patient with iron-deficiency anemia or with low hemoglobin will take iron replacement as recommended by health care provider, resulting in laboratory results within the desired range.

Nursing Interventions

- Encourage patient to eat a nutritious diet to obtain sufficient iron. Iron supplements are not needed unless the person is malnourished or pregnant or has abnormal menses.
- Store drug in light-resistant container.
- Administer IM injection of iron by the Z-track method to avoid leakage of iron into the subcutaneous tissue and skin, resulting in irritation and stains to the skin.

Patient Teaching

General

- Advise patient to take the tablet or capsule between meals with at least 8 ounces of juice or water to promote absorption. If gastric irritation occurs, instruct the patient to take with food.
- Advise patient to swallow the tablet or capsule whole.
- Encourage patient to maintain upright position for 30 minutes after taking oral iron preparation to prevent esophageal corrosion from reflux.
- Do not administer the iron tablet within 1 hour of ingesting antacid, milk, ice cream, or other milk products.
- Counsel patient that certain herbal drugs can decrease absorption of iron and other minerals (see Herbal Alert 15-1).
- Advise patient to increase fluids, activity, and dietary bulk to avoid or relieve constipation. Slow-release iron capsules decrease constipation and gastric irritation.
- Instruct adults not to leave iron tablets within reach of children. If a child swallows many tablets, induce vomiting and immediately call the local poison control center; the telephone number is in the front of most telephone books (include this number on emergency reference list).
- Encourage patient to take only the prescribed amount of drug to avoid iron poisoning. Be alert to iron in many multivitamin preparations.
- Be alert that iron content varies among iron salts; therefore do not substitute one for another.
- Advise patient that drug treatment for anemia is generally less than 6 months.

Diet

- Counsel patient to include iron-rich foods in diet, such as lean meats, egg yolk, dried beans, green vegetables, and fruit.

Side Effects

- Advise patient taking the liquid iron preparation to use a straw to prevent discoloration of tooth enamel.
- Alert patient that the drug turns stools a harmless black or dark green.
- Instruct patient about signs and symptoms of toxicity, including nausea, vomiting, diarrhea, pallor, hematemesis, shock, and coma, and report occurrence to health care provider.

Cultural Considerations

- Ask about cultural practices and incorporate them as appropriate.
- Use interpreter as needed.

Evaluation

- Evaluate the effectiveness of iron therapy by determining that patient is not fatigued or short of breath and that hemoglobin level is within desired range.

CRITICAL THINKING CASE STUDY

AP is pregnant and is taking two 325-mg tablets of ferrous sulfate. She has a 2-year-old daughter.

1. What precautions should AP take in regard to the container of ferrous sulfate? Explain your answer.
2. If AP asks whether she should take more than two tablets of iron per day, how should the nurse respond?
3. AP states that she is constipated and wonders whether iron is the cause. How can this problem be alleviated? What would be an appropriate response?
4. Develop a safety plan with AP related to medication safety in the home with children.

NCLEX STUDY QUESTIONS

1. The nurse is reviewing a patient's laboratory test results and current medications and notes that the patient's prothrombin time is prolonged. The nurse checks the patient's medication list. What vitamin or mineral might be contributing to this?
   a. Vitamin A
   b. Selenium
   c. Vitamin D
   d. Vitamin E
2. A patient comes to the office with a chief complaint of hair loss and peeling skin. The nurse notes that many vitamins and minerals are on the list of medications that the patient reports using to treat liver disease. The patient's complaint may be caused by excess of what vitamin or mineral?
   a. Vitamin A
   b. Zinc
   c. Vitamin C
   d. Vitamin D
3. The nurse routinely includes health teaching about vitamins to patients. Vitamin D has a major role in which process?
   a. Ensuring night and color vision
   b. Regulating calcium and phosphorous metabolism
   c. Body growth
   d. DNA and prothrombin synthesis
4. The nurse is doing preconception counseling with a patient. Folic acid is included in the health teaching plan because it is known to prevent CNS anomalies and may offer protection from which disorder?
   a. Colorectal cancer
   b. Diabetes mellitus
   c. Celiac disease
   d. Migraine headaches
5. A prenatal patient tells the nurse that she is not taking vitamins because she heard that vitamins may cause damage to the fetus if she becomes pregnant. What is the nurse's best response?
   a. "Vitamins can only help you and your baby."
   b. "Take extra vitamins now to make up for missed doses."
   c. "Megadoses of vitamins can be harmful in the first trimester."
   d. "Taking above the RDA of any vitamin is not recommended."
6. A patient asks the nurse for information about fat-soluble vitamins. What is the nurse's best response?
   a. "Fat-soluble vitamins are metabolized rapidly."
   b. "Fat-soluble vitamins cannot be stored in the liver."
   c. "Fat-soluble vitamins are excreted slowly in urine."
   d. "Fat-soluble vitamins can never be toxic."
7. A patient complains of night blindness. The nurse correctly recommends which foods?
   a. Skim milk and peas
   b. Fortified milk and eggs
   c. Nuts and yeast
   d. Enriched bread and cereal
8. A patient diagnosed with alcoholism has questions about his medications. The nurse correctly explains that alcoholism can be associated with deficiency of which vitamin?
   a. A
   b. B_{12}
   c. D
   d. K
9. A patient complains of anorexia, nausea, and vomiting. The patient's list of medications includes multiple large doses of vitamins. The nurse notes that the patient's complaints may be related to early signs of toxicity of which vitamin?
   a. A
   b. B
   c. C
   d. D
10. A patient takes iron on a daily basis. Which comment from the patient suggests the need for health teaching related to iron?
    a. "I will swallow the tablet whole."
    b. "I take the tablet immediately before I go to bed."
    c. "I know that multivitamins might include iron."
    d. "I keep the tablets out of my children's reach."
11. A patient asks the nurse, "What does copper do for me? I think it must be bad for me." What is the nurse's best response?
    a. "Copper is needed for red blood cell formation."
    b. "Be sure to include nuts and seeds in your diet."
    c. "Why do you think copper is bad for you?"
    d. "Are you taking 5 mg of copper a day?"

Answers: 1, d; 2, a; 3, b; 4, a; 5, c; 6, c; 7, b; 8, b; 9, d; 10, b; 11, c.

- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Describe osmolality and tonicity.
- Discuss normal range for serum osmolality and tonicity of intravenous solutions.
- Describe the classifications of intravenous fluids.
- Discuss the functions of major electrolytes.
- Differentiate between major intracellular and extracellular electrolytes.
- Explain the difference between cations and anions.
- Describe major signs and symptoms of deficiency and excess of potassium, sodium, calcium, magnesium, chloride, and phosphorus.
- Explain the methods used to correct potassium, calcium, and magnesium excess.
- Apply the nursing process to the care of the patient experiencing fluid, potassium, sodium, calcium, and magnesium imbalances.

TABLE 16-1 **ADULT BODY FLUID VOLUME**

FLUID COMPARTMENT	PERCENTAGE
Intracellular fluid	40%
Extracellular fluid	20%
Interstitial fluid	15%
Intravascular fluid	5%
Transcellular fluid	Approximately 1-2 L total, but generally not included in calculations
Total body fluid	60%

TABLE 16-2 **CATIONS AND ANIONS**

CATIONS	ANIONS
Potassium (K$^+$)	Chloride (Cl$^-$)
Sodium (Na$^+$)	Bicarbonate (HCO$_3^-$)
Calcium (Ca^{2+})	Phosphate (PO$_4^-$)
Magnesium (Mg^{2+})	Sulfate (SO$_4^-$)

TABLE 16-3 **ELECTROLYTE CONCENTRATION IN BODY FLUIDS**

INTRACELLULAR FLUID	EXTRACELLULAR FLUID
Major Cations	**Major Cations**
Potassium	Sodium
Magnesium	Potassium
Sodium	Calcium
	Magnesium
Major Anions	**Major Anions**
Phosphorus	Chloride
	Phosphorus

Fluid and electrolyte balance is necessary to maintain homeostasis. Intake must equal output to maintain fluid balance, and the body constantly strives for equilibrium. The kidneys, with the respiratory, endocrine, gastrointestinal (GI), and integumentary systems, regulate fluid and electrolyte balance.

The total body water of a 70-kg man is approximately 60% (40 L). This percentage varies with age, gender, and percentage of body fat. Neonates have 70% to 80% water, whereas older adults have 45% to 55% water. Women tend to have less body water than men due to effects of hormones and to higher amount of adipose tissue, which contains very little water. Total body water is contained in two major compartments: the intracellular fluid (ICF) compartment and the extracellular fluid (ECF) compartment. The ECF compartment is composed of plasma (intravascular), intrastitial fluid (surrounding cells), and transcellular fluid, also known as the third-space (mucus and GI, cerebrospinal, pericardial, synovial, and ocular fluids). Table 16-1 shows the fluid compartments and percentage of total body water. Fluids move freely between the intracellular and extracellular compartments to maintain balance and homeostasis.

Electrolytes are substances that separate or dissociate into ions (charged particles) in solution; they are abundant in both ICF and ECF. Ions carry either a positive charge **(cation)** or a negative charge **(anion).** Major cations and anions are listed in Table 16-2. Electrolyte balance is essential for normal physiologic functioning and is closely linked with fluid balance. In addition, most electrolytes interact with hydrogen ions to maintain acid-base balance. Electrolyte balance must be kept within a narrow range to maintain homeostasis. Many illnesses and body system alterations cause electrolyte imbalances, which must be corrected quickly before serious sequelae ensue.

The major electrolytes in body fluids are sodium, potassium, calcium, magnesium, chloride, phosphorus, sulfate, hydrogen and bicarbonate ions, and many proteins. Electrolyte concentration differs in ICF and ECF. Table 16-3 lists the major cations and anions found in body fluid.

Administering intravenous (IV) fluids and electrolyte replacements may be thought of as "routine" nursing care but requires as much diligence and critical thinking as administration of any medication. This chapter describes fluid replacement strategies, pharmacologic management of specific electrolyte imbalances, and nursing care of patients with fluid and electrolyte imbalances.

HOMEOSTASIS

Two principles stand out when considering homeostasis and fluid and electrolyte balance. The first principle is that anions and cations must be balanced within each compartment and remain electrically neutral. The amount of fluid within each compartment remains constant. Compartments work continuously to maintain fluid balance and replace and exchange ions to maintain neutrality. The second principle is that the fluid compartments remain in osmotic equilibrium (except for transient changes).

Movement of fluid and particles between and within compartments is controlled by a number of processes, including osmosis, diffusion, membrane transport, hydrostatic pressure, membrane permeability, colloidal osmotic pressure (plasma proteins), and size of the particle (ion). The number of solutes in a solution is expressed as a unit of measurement called the **osmole,** which is particularly useful when referencing osmotic solutions.

Osmolality and osmolarity are two different terms of measurement used to describe the number of osmoles or solutes in a solution. In clinical practice, the difference between the absolute values of these two measurements is negligible. Hence, these terms are often used interchangeably. However, they are two separate measurements. **Osmolality** refers to the number of osmoles per kilogram of water and is expressed as mmol/kg (SI units) or mOsm/kg (conventional units). Osmolality is the concentration of fluid that affects the movement of water between compartments by osmosis. **Osmolarity** is the number of osmoles in 1 L of solution and is expressed as mmol/L (SI units) or mOsm/L (conventional units).

Osmolality

Osmolality refers to the number of particles dissolved in the serum, primarily sodium, urea (blood urea nitrogen [BUN]), and glucose. It also is a measure of the concentration of solutes per kilogram in urine. Normal serum osmolality ranges from 280 to 300 mOsm/kg. As the number of particles increases, the concentration of the solution also increases. The change in the concentration of particles will affect chemical behavior and movement of water. Sodium is the primary electrolyte in the ECF and keeps water in this compartment.

The following three types of fluid concentration are based on the osmolality of body fluids:

1. **Iso-osmolar** fluid has the same proportion of weight of particles (e.g., sodium, glucose) and water.
2. **Hypo-osmolar** fluid contains fewer particles than water.
3. **Hyperosmolar** fluid contains more particles than water. The plasma/serum osmolality (concentration of circulating body fluids) can be calculated if the serum sodium level is known or the sodium, glucose, and BUN levels are known.

Hypo-osmolality of body fluid may be the result of excess water intake or fluid overload (edema) caused by an inability to excrete excess water. Hyperosmolality of body fluid could be caused by severe diarrhea, increased salt and solutes (protein) intake, inadequate water intake, diabetes, ketoacidosis, or sweating.

Osmolality and Tonicity

The terms *osmolality* and *tonicity* have been used interchangeably; they are similar but not identical. Osmolality refers to the concentration of particles in a solution and is used in reference to body fluids. **Tonicity** is used primarily as a measurement of the concentration of IV solutions compared with the osmolality of body fluids.

FLUID REPLACEMENT

General Considerations

All routes of fluid intake and loss must be considered when assessing fluid balance. General guidelines can be used as the basis for establishing fluid needs. The recommended water intake for a healthy adult is 3.7 L for a man and 2.7 L for a woman, or approximately 30 to 40 mL/kg/d. Patients lose water daily through various routes: about 350 mL through respiration; 450 mL through skin in perspiration and evaporation; 1400 mL in urine; and 200 mL in feces. Insensible losses (water lost via the lungs, skin, and feces) are not measurable. The minimum urinary output for an adult is 0.5 to 1 mL/kg/h or 35 to 70 mL/h for the 70-kg patient.

Daily water requirements differ according to the patient's age and medical problems. Fluid maintenance needs for the NPO (nothing by mouth) patient can be calculated as follows: 4 mL/kg/h for first 10 kg of weight; 2 mL/kg/h for second 10 kg of weight; 1 mL/kg/h for every kg of weight thereafter. Using this formula, a 70-kg patient would require 110 mL/h of IV fluid (IVF), or 2640 mL/d.

IVFs are ordered based on an evaluation of the patient's fluid and electrolyte balance, fluid requirements, and fluid needs. Several questions must be addressed. Is the purpose of IV therapy replacement or maintenance? What are the patient's water, electrolyte, and protein requirements? The patient's weight, caloric needs, and body surface area are other important considerations. Illness and surgery increase the amount of fluids lost and affect fluid and electrolyte needs. Ongoing assessment and monitoring the patient's responses to fluid and electrolyte therapy is vital for patients with fluid and electrolyte imbalances.

Intravenous Solutions

With fluid volume deficit (FVD) from the extracellular body compartment, fluid is lost from the interstitial and vascular spaces. Different types and concentrations of IVFs are available to replace body fluid losses.

Types of Intravenous Solutions

The three general classifications of IV solutions used for fluid replacement are crystalloids (with and without added electrolytes), colloids, and blood and blood products.

Crystalloids

Crystalloid solutions contain fluids and electrolytes and are able to freely cross capillary walls. They do not contain any proteins, which are necessary to maintain the colloidal oncotic pressure that prevents water from leaving the intravascular space. Crystalloids are used to treat dehydration and electrolyte imbalances and as short-term maintenance fluids. Crystalloids cause early plasma expansion but have a shorter duration of action than colloid solutions.

Crystalloid IVFs are classified by their total osmolality when compared with the osmolality of serum. The three major classifications of crystalloid IVF are isotonic, hypotonic, and hypertonic (Table 16-4):

- **Isotonic** solutions have the same approximate osmolality as ECF or plasma. Because of the osmotic equilibrium, water does not enter or leave the cell; therefore, there is no effect on red blood cells (RBCs). Isotonic solutions are primarily used for hydration and to expand ECF volume, because the fluid remains in the intravascular space.
- **Hypotonic** solutions exert less osmotic pressure than ECF, which allows water to move into the cell. IV infusions of hypotonic solutions result in an increased solute concentration in the intravascular space, causing fluid to move into the intracellular and interstitial spaces. Excessive infusion of hypotonic solutions may cause hemolysis, decreased blood pressure, and decreased IVF volume.
- **Hypertonic** solutions exert greater osmotic pressure than ECF, resulting in a higher solute concentration than the serum. When administered, hypertonic IVF fluids pull water from the interstitial space to the ECF via osmosis and cause cell shrinkage. Patients receiving hypertonic solutions must be monitored carefully for signs of circulatory overload (because of the increase in ECF volume).

TABLE 16-4 TONICITY OF INTRAVENOUS SOLUTIONS

TONICITY OF SOLUTION AND OSMOLALITY (mOsm/kg)	EXAMPLES OF IVF AND APPROXIMATE* OSMOLARITY (mOsm/L)	GENERAL INDICATIONS AND CAUTIONS FOR USE
Isotonic (280-300)	Lactated Ringer's solution (275) Ringer's solution (275) Normal saline (308) 5% Dextrose and water (250) (may be classified as hypotonic and isotonic; initially isotonic, then metabolized to hypotonic) Plasma-Lyte (294)	Lactated Ringer's solution provides electrolytes (balanced electrolyte solution). Cautious use in patients with renal failure (contains K^+) and in patients with alkalosis; liver converts Lactated Ringer's solution to bicarbonate **Hydration** Corrects dehydration and sodium depletion Replaces gastrointestinal losses Dextrose provides some calories Caution with use in patients with cardiac or renal disease; risk for fluid volume overload Do not administer isotonic solutions to patients with known or suspected increased intracranial pressure (ICP)
Hypotonic (<280)	0.45% Normal saline (154) 0.33% NaCl (103) 2.5% Dextrose and water (126)	Replaces cellular fluid; treats intracellular dehydration (diabetic ketoacidosis, hyperosmolar hyperglycemic state) Provides free water to allow excretion of body wastes Dextrose provides some calories Do not administer hypotonic solutions to patients with known or suspected ICP or patients with liver disease, shock, trauma, or burns (risk of depleting intravascular volume) Monitor for signs of FVD; monitor for worsening hypovolemia due to decrease in vascular volume
Hypertonic >300	3% Sodium chloride (513) 5% Dextrose and 0.45% normal saline (408) 5% Dextrose and normal saline (560) 5% Dextrose in Lactated Ringer's (525) 10% Dextrose and water (505) 50% Dextrose and water (2526)	Increases serum osmolality Corrects severe hyponatremia; decreases ICP in patients with cerebral edema Dextrose provides some calories Cautious use, may cause intravascular volume overload and pulmonary edema; administer slowly and carefully with infusion control device; for use only in critical care areas and constant monitoring; monitor electrolytes and for signs of FVE Avoid prolonged use Contraindicated for patients with cardiac or renal disease and those with dehydration or diabetic ketoacidosis Higher concentrations of dextrose (>10%) must be given through a central venous access device; may be added to amino acid solutions as total parenteral nutrition

*Refer to manufacturer's label on individual bags of IVF for exact osmolarity.

Parenteral solutions containing dextrose are available in different concentrations and in combination with other solutions, such as normal saline and lactated Ringer's solution. Dextrose solutions provide hydration and some calories and increase glucose levels in the blood. Dextrose solutions are also used to dilute IV medications for administration after compatibility between IVF and the medication has been verified. Dextrose may also affect the stability of some medications; a pharmacist should be consulted if there are questions regarding admixtures. The addition of dextrose to an IV solution affects the tonicity of the solution after it is infused. Five-percent dextrose solutions are hypertonic when added to normal saline or lactated Ringer's solution, but the remaining solution is isotonic because the dextrose is quickly metabolized to carbon dioxide and water.

The Infusion Nursing Society's Practice Guidelines recommend that dextrose solutions higher than 10% should be given via a central vein. An exception is 50% dextrose, which may be given in small amounts via a peripheral vein to correct hypoglycemia. Dextrose can be irritating to veins due to the pH of the solution (3.4 to 4). If hypertonic solutions are not diluted and given peripherally, there is a risk of vein irritation, damage, and thrombosis. Long-term use of hypertonic solutions may result in electrolyte depletion, increased intravascular volume, fluid overload, water intoxication, and pulmonary edema. Rapid infusions of dextrose solutions may cause hyperglycemia, which can lead to osmotic diuresis and fluid and electrolyte imbalance. Hypertonic IV solutions should be administered in a critical care unit, where the staffing ratio allows continuous monitoring for complications. To decrease medication errors with hypertonic solutions, hospitals may limit access of these solutions and dispense them only directly from the pharmacy.

Sodium solutions are available in various concentrations and tonicities. Isotonic solutions are primarily used for hydration to expand the ECF and during blood product transfusions. Rapid infusion of isotonic saline solutions may lead to hypernatremia, fluid volume excess (FVE), and electrolyte depletion. Long-term use should also be avoided, as normal saline provides no calories. Hypotonic solutions are also used for hydration and to treat hyperosmolar diabetes. Hypertonic saline solutions are used to treat severe hyponatremia or hypochloremia; careful monitoring of electrolyte levels is important to avoid excess replacement.

Balanced electrolyte solutions, such as lactated Ringer's solution and Ringer's solution, contain electrolytes (no magnesium) and minimal calories with the addition of dextrose. Their primary use is hydration and electrolyte replacement. However, they do not provide adequate electrolytes for maintenance therapy for patients with limited or no oral intake. Lactated Ringer's solution is similar in electrolyte content to plasma. Lactate is added as a buffering agent and is metabolized to bicarbonate. Complications of infusions of Ringer's and lactated Ringer's include fluid overload, excess electrolytes, and metabolic acidosis with long-term therapy. Because lactate is metabolized in the liver, lactated Ringer's is contraindicated for patients with liver disease.

Colloids

Colloid solutions contain protein or other large molecular substances that increase osmolarity without dissolving in the solution. Because of their size, the particles are unable to pass through the semipermeable membranes of the capillary walls and stay within the intravascular compartment; thus, colloids are also known as plasma expanders. They act by increasing the colloidal oncotic pressure and pulling fluids from the interstitial space into the plasma, increasing blood volume. The composition of colloid solutions includes proteins, carbohydrates, and lipids. Colloids typically have small and large particles, except albumin, whose particles are all one size. Commonly used colloids are shown in Table 16-5.

Blood and Blood Products

Blood and blood products include whole blood and the components that can be processed through centrifugation methods. Blood products include packed RBCs (PRBCs), plasma, platelets, and cryoprecipitate. Plasma can be further processed into volume expanders, coagulation factor concentrates, and immune globins. A unit of PRBCs contains concentrated RBCs with most of the plasma and platelets removed; approximate volume is 350 mL/unit. The approximate volume of a unit of whole blood is 500 mL/unit. Advantages of infusing PRBCs over whole blood are that infusing packed cells allows an increase in oxygen-carrying capacity with a smaller volume, and other portions of the blood can be processed for other therapies. One unit of whole blood elevates the hemoglobin by approximately 0.5 to 1 g/dL, and one unit of packed RBCs elevates the hematocrit by three points.

It is critical for nurses to understand the specific blood component to be infused *before* beginning the infusion. Reducing errors and increasing patient safety during blood and blood product transfusions is a focus of the Joint Commission on Accreditation of Health Care Organizations and is one of the 2013 National Patient Safety Goals. The National Healthcare Safety Network's Hemovigilance Module was developed to increase patient safety and decrease costs associated with transfusion-related adverse events.

The maximum rate of infusion is 4 hours per unit, beginning with removal of the unit from the refrigerator. Loop diuretics are often prescribed to patients receiving whole blood or PRBCs to prevent circulatory overload, particularly in patients who are at risk for developing pulmonary edema and FVE. For patients receiving multiple blood transfusions, the serum ionized calcium level should be monitored. Both PRBCs and whole blood are processed using sodium citrate and citric acid for anticoagulation; multiple blood transfusions can result in a decrease in the plasma ionized (free) calcium levels. Practice guidelines are available from the American Red Cross (see Key Websites).

IV lipid emulsions are indicated for patients who are unable to tolerate oral or enteral feedings for 7 days or more. Lipids can supply up to 30% of the patient's caloric intake. Parenteral nutrition provides essential nutrients intravenously, including proteins, carbohydrates, electrolytes, trace minerals, and vitamins. Lipids are often added to parenteral nutrition formulas; these formulas are referred to as total nutrient admixture. The patient must have a centrally or peripherally inserted vascular access device to receive parenteral nutrition formulas (see Chapter 17).

Nursing Process

Patient-Centered Collaborative Care

Fluid Imbalance

Assessment

- Identify patient at risk for FVD and FVE. Contributing factors for FVD include prolonged inadequate intake, lack of access or inability to obtain fluids, excessive losses due to bleeding or trauma, and GI losses. Contributing factors for FVE include heart failure, liver disease, kidney failure, excessive sodium intake, and excessive or too rapid infusion of IVF.
- Assess patient's history to identify factors that may contribute to FVD and FVE.
- Differentiate between causes of deficient fluid volume, including hypovolemia and dehydration.
- Assess vital signs and patient's usual baseline values. Report abnormal findings.

TABLE 16-5 COMMON COLLOID SOLUTIONS

COMMON SOLUTIONS	INDICATIONS	NURSING IMPLICATIONS	ADVERSE EFFECTS AND CONTRAINDICATIONS
High–molecular-weight dextran (6% dextran 70 and 75) (synthetic colloids)	Treatment of shock caused by hemorrhage, burns, or trauma Maximum volume-expansion effect 1 hour after administration With normal renal functioning, increased volume is excreted within 24 hours	Administer colloid solutions with an 18-g or larger needle Dextran solutions are not a substitute for blood products and have no oxygen-carrying capacity Can be used emergently if cross-matching or blood products are unavailable May interfere with laboratory testing for typing and cross-matching; draw necessary blood samples before administration Increased volume may cause dilutional hemoglobin and hematocrit Assess fluid volume status, may cause circulatory overload Monitor for signs and symptoms of FVE	Wheezing, urticaria, chest tightness, nausea, and vomiting Anaphylactoid reactions are rare, but potentially fatal Contraindicated for patients with renal disease, heart failure, and bleeding disorders
Low–molecular-weight dextran 40 (6%) (synthetic colloids)	Intraoperative prophylaxis of venous and pulmonary embolism Early fluid replacement and treatment of hypovolemic shock	Same as for high–molecular-weight dextran	Same as for high–molecular-weight dextran
Hydroxyethyl starch (Hetastarch) 6% (synthetic polymer closely related to human albumin)	Early fluid replacement and treatment of hypovolemic shock, burns Maximum volume expansion shortly after infusion completed; duration of action 24-36 hours	Hetastarch 6% with 0.9% NaCl is isotonic (310 mOsm/L) Hetastarch 6% with 7.2% NaCl is hypertonic Does not interfere with blood typing and cross-matching Assess fluid volume status, may cause circulatory overload	Severe anaphylactic reaction Interferes with platelet function, increases bleeding time Contraindicated for patients with bleeding disorders and renal, cardiac, and liver disease
Albumin (5% and 25%) Prepared from human blood and blood products; considered a blood product	Regulates plasma volume and tissue fluid balance 5% solution is isotonic; used to treat hypovolemia 25% solution is hypertonic; generally used for patients with fluid and sodium restrictions	Assess fluid volume status, may cause circulatory overload	Contraindicated in patients with heart failure or severe anemia Hold ACEI at least 24 hours before administering albumin due to the risk of adverse reactions including hypotension and flushing

- Assess patient's laboratory values. Plasma or serum osmolality is the primary indicator of patient's hydration status
- Determine adequate urine output for patient based on weight and renal function.
- Obtain urine specific gravity (SG). Normal range is 1.005 to 1.030.
- Check types of IVF ordered per day, including amount to be infused, hourly rate, and solution for tonicity and electrolyte content. Consider if fluid ordered is appropriate for patient's history and clinical condition; collaborate with licensed provider to determine appropriate fluid replacement for patient. Excessive administration of IVF containing sodium to patients with altered regulatory mechanisms may precipitate FVE.
- Assess patient's usual weight.

Nursing Diagnoses

- Deficient fluid volume related to fluid loss and/or inadequate fluid intake, failure of regulatory mechanisms
- FVE related to altered regulatory mechanisms and excess fluid or sodium intake

Planning

- Patient will exhibit balanced fluid volume.
- Patient will have balanced intake and output over 24-hour period.
- Patient will be hydrated as evidenced by moist mucous membranes, elastic skin turgor, vital signs; adequate urine output; urine SG between 1.005 and 1.010; stable weight; and no changes in mental status.
- Patient will not exhibit signs of circulatory overload.
- Patient and family will verbalize understanding of teaching and factors related to FVD and FVE.

Nursing Interventions

General

- Monitor and record vital signs; assess trends and deviation from patient's baseline. Report significant changes to health care provider.
- Measure and record intake and output every 1 to 4 hours, including all forms of output. Measure urine SG.
- Monitor types of fluids patient is receiving. Report if only one type of IVF is prescribed daily. This can cause fluid imbalance.
- Use strict aseptic technique when inserting IV access devices. Check IV site for patency and signs of complications such as phlebitis and infiltration. Adhere to agency policy regarding site rotation and dressing and tubing changes. Avoid contamination when administering IV medications. Follow evidence-based practice guidelines, and implement interventions to decrease central line–associated infections.
- Monitor IV infusion at least hourly; ensure that prescribed amount infuses hourly. Set IV pump correctly, and validate correct drip rate.
- Measure patient's weight daily at the same time, using the same scale, with the same amount of clothing. A gain of 1 kg (2.2 to 2.5 lb) is equivalent to 1 L of fluid.

FVD

- Administer isotonic IVF as ordered.
- Monitor strict intake and output hourly. Encourage frequent oral intake if patient is able. Provide oral care if patient is unable to perform independently. Moisturize skin to prevent dryness; reposition patient every 2 hours, padding bony prominences; and monitor frequently for skin breakdown and pressure.
- Monitor for signs and symptoms of FVD as a result of dehydration, including excess thirst (mild dehydration). Marked thirst, dry mucous membranes, poor skin turgor, decreased urine output, tachycardia, changes in mental status, and slightly decreased systolic blood pressure are indicators of marked dehydration. Dehydration can also result from third-spacing of fluid; although the central volume is low, the patient may exhibit weight gain and generalized edema, atypical of the usual presentation of FVD.
- Monitor vital signs for indications of FVD including increased temperature, weak pulse, tachycardia, hypotension, and tachypnea. Assess for orthostatic hypotension, which can occur with hypovolemia. Use safety precautions when transferring the patient from bed to chair, avoiding abrupt changes in position. Other signs and symptoms of FVD include flattened neck veins; weight loss; decreased skin turgor; dry mucous membranes; oliguria; concentrated urine; decreased capillary refill; pale, cool, clammy skin; and muscle weakness.
- Monitor laboratory values associated with FVD daily, including increased hemoglobin and hematocrit; urine SG >1.030; and increased sodium, BUN, and serum osmolality. When evaluating increased BUN, it is important to review serum creatinine results. Elevated BUN can indicate dehydration, but BUN may also be elevated for other reasons, including excessive protein breakdown. Assessing serum creatinine will determine degree of renal impairment. Evaluate electrolyte levels for imbalances.

FVE

- Monitor and record vital signs indicating FVE, including tachycardia, bounding pulse, tachypnea, increased blood pressure, and increased pulse pressure. Other signs and symptoms of FVE include altered mental status; generalized edema; anasarca; constant, irritated cough; dyspnea; orthopnea; crackles; pulmonary congestion; muffled heart sounds; fatigue; weight gain; increased central venous pressure; jugular vein distention; and increased urine output.
- Monitor laboratory results associated with FVE daily, including elevated BUN, hemoglobin and hematocrit, sodium, serum osmolality, and urine SG <1.010. Monitor electrolytes for imbalances, and creatinine and albumin levels. Chest x-ray may reveal pulmonary congestion.
- Administer diuretics as ordered; implement fluid and sodium restrictions. Recommend a nutritionist consult if warranted. Position patient with head of bed elevated to facilitate ease of respiration, and provide additional pillows if necessary. Monitor edematous areas for signs of pressure and altered skin integrity. Provide meticulous skin care, and reposition patient at least every 2 hours.

Patient Teaching

- Instruct patient that thirst means a mild ECF deficit. Oral fluid intake is the best means of fluid replacement. Increasing fluid intake is important; older patients' thirst mechanisms are frequently decreased. The nurse should offer fluids frequently on a scheduled basis to older adults.
- Advise patient to report frequent vomiting or diarrhea. When vomiting and diarrhea occur constantly or over several days, severe fluid volume and electrolyte imbalance can result.
- Assist patient to plan a typical 24-hour intake based on individual fluid needs. Encourage patient to monitor fluid intake and output. Advise patient to report to the health care provider any abnormal findings, such as changes in urination patterns, fatigue, shortness of breath, weight gain (>2 lb/d or >5 lb/wk) or loss, peripheral edema, or tight shoes and rings. Encourage patient to drink adequate fluids daily, and involve family for support.

Cultural Considerations

- Use an interpreter as appropriate.
- Involve the extended family in health teaching and support.
- Incorporate food choices that are culturally acceptable.

Evaluation

- Patient's vital signs remain within normal limits.
- Fluid intake is balanced with output. Urine output is adequate for age, weight, and history.
- Patient and family understand treatment plan and expected outcomes.
- IVFs are administered as ordered without complications or harm to patient.

ELECTROLYTES

Potassium

Potassium (K^+) is the major intracellular cation; 98% of the body's potassium is found within the cells, and 2% is found in the ECF. Potassium is essential for neuromuscular activity and cellular metabolism. Potassium levels affect cardiac and skeletal muscle activity.

Potassium moves in and out of the cells under the influence of the potassium-sodium pump. Acid-base balance also influences potassium levels. Acidotic conditions tend to pull potassium out of cells; alkalotic conditions tend to put potassium back into cells. Normal renal functioning is needed to maintain potassium balance; the majority is excreted via the kidneys, although the kidneys do not regulate excretion of potassium as well as they conserve sodium. Aldosterone also plays a role in the excretion of potassium.

Daily dietary intake is necessary because potassium is poorly stored in the body. Recommended potassium intake is about 40 to 60 mEq daily, either in potassium-rich foods or as potassium supplements. Foods rich in potassium include tuna fish and fruits and vegetables such as mangoes, avocados, tomatoes, cucumbers, spinach, and bananas.

Functions

Potassium is necessary for transmission and conduction of nerve impulses and for contraction of skeletal, cardiac, and smooth muscles. It is also necessary for normal kidney function and for the enzyme action used to change carbohydrates to energy (glycolysis) and amino acids to protein. Potassium promotes glycogen storage in hepatic cells, regulates the osmolality of cellular fluids, and plays a role in acid-base balance.

Hypokalemia

Hypokalemia, or potassium deficit, occurs with serum levels <3.5 mEq/L. Most cases of hypokalemia are caused by excessive loss rather than deficient intake. Whenever cells are damaged from trauma, injury, surgery, or shock, potassium leaks from the cells into the intravascular fluid and is excreted by the kidneys. With cellular loss of potassium, potassium shifts from the blood plasma into the cell to restore the cellular potassium balance; hypokalemia usually results. GI sources of potassium loss include vomiting, diarrhea, suctioning, recent ileostomy formation, and draining fistulae. Between 80% and 90% of potassium in the body is excreted in the urine; 8% is excreted in the feces. Major causes of potassium loss are vomiting, diarrhea, or as a result of diuretic therapy. Other causes include burns, total parenteral nutrition therapy, alkalosis, prolonged laxative use, excessive licorice consumption, corticosteroid use, increased aldosterone levels, and decreased magnesium levels.

Hypokalemia may not be symptomatic until potassium levels are <3.0 mEq/L. It is important to recognize early signs and symptoms to prevent severe hypokalemia, which can result in cardiac arrest and death. Early clinical manifestations include fatigue, muscle weakness, anorexia, nausea, and vomiting. Muscle weakness does not usually occur until potassium levels are <2.5 mEq/L. Weakness usually begins in the lower extremities, progresses cephalad to the trunk, and may result in paralysis; respiratory muscle involvement may result in respiratory arrest. Quadricep weakness may be one of the earliest signs. Severe signs and symptoms include paresthesias, leg cramps, decreased bowel motility and paralytic ileus, confusion, rhabdomyolysis and myoglobinuria, atrial and ventricular dysrhythmias, and cardiac arrest. Electrocardiogram (ECG) changes include flattened or inverted T waves and depressed ST segments. Patients at risk for hypokalemia-induced dysrhythmias include older adults, those with heart disease or co-existing hypomagnesemia, and those on digoxin or other antiarrhythmics. Certain drugs, such as potassium-wasting diuretics and cortisone preparations, promote potassium loss. Patients receiving these drugs should increase their potassium intake by consuming foods rich in potassium or taking potassium supplements as prescribed by their health care provider. Serum potassium levels should be monitored periodically for abnormalities.

Treatment for hypokalemia due to excessive potassium loss depends on the severity of the deficit. Patients with low-normal serum potassium levels may be advised to consume additional foods high in potassium. Usual dietary potassium intake for adults is 50 to 100 mEq daily; typically, a loss of 200 mEq or more is sufficient to cause hypokalemia. Management goals for patients with hypokalemia include preventing and treating life-threatening complications, replacing potassium and returning levels to normal, and diagnosing and correcting the cause of the deficiency.

Potassium replacements can be given orally or intravenously (Box 16-1). Table 16-6 lists the potassium preparations used to treat hypokalemia, and Prototype Drug Chart 16-1 compares the pharmacokinetics and pharmacodynamics of oral and IV potassium preparations.

Pharmacodynamics Potassium maintains neuromuscular activity. Onset of action of oral potassium may be within 30 minutes; for IV potassium, it is immediate. Duration of action of potassium is not known; however, it may vary according to the dose taken. ECG and serum potassium levels should be closely monitored when large doses are administered.

BOX 16-1 ORAL AND IV POTASSIUM PREPARATIONS

Oral Potassium Preparations

- Potassium bicarbonate: Indicated for use in patients with hypokalemia and metabolic acidosis. (Potassium acetate available for IV administration.)
- Potassium phosphate: Found primarily in food. Indicated for patients with hypokalemia and hypophosphatemia.
- Potassium gluconate: available as elixir or tablet
- Potassium chloride: All other indications, including hypokalemic alkalosis. Raises serum K^+ level faster than potassium bicarbonate. Available as liquid, powder, tablet, capsule, crystalline (salt substitute), controlled-release microencapsulated tablets, wax-matrix–extended-release tablets, enteric-coated tablets, and effervescent tablets for solution.

Nursing Implications for Oral Preparations

- Liquid forms are inexpensive but not palatable. Must be diluted in water or juice; follow manufacturer's instructions (minimum amount for dilution 90 mL). Follow with a large glass of water to enhance esophageal peristalsis. Dilute liquid forms before administering via enteral feeding tube.
- Administer medication with food and while patient is sitting up to prevent esophagitis. Instruct patient to remain upright at least 30 minutes after administration. Any form may cause nausea and vomiting. Large tablets may be difficult to swallow.
- Advise patient not to suck on tablets to avoid oral ulceration. Extended-release forms may not be crushed or chewed.
- Enteric-coated tablets are associated with small bowel ulceration; wax-matrix tablets may cause small bowel ulceration, stricture, and perforation. Advise patient that wax-matrix casing may be visible in stool. Risk of gastrointestinal side effects lowest with microencapsulated preparations.
- Assess potassium levels after 60 mEq of K^+; if immediate-acting form is given, draw K^+ level after 60 minutes; for sustained-release forms, draw K^+ level after 3 hours. Patients on maintenance doses should have periodic levels drawn by the primary care provider.

Nursing Implications for Intravenous Potassium Administration

- IV therapy is indicated for patients unable to tolerate oral therapy or in addition to oral therapy for patients with severe hypokalemia.
- Only *diluted* potassium chloride may be administered IV; concentrated KCl is *never* administered IV; KCl is *never* given by direct injection into the vein.*
- Monitor IV site and infusion carefully, avoid extravasation and infiltration.
- Too rapid infusion may cause fatal hyperkalemia.
- Administer via peripheral or central vein. *Must be administered with a calibrated infusion device. Refer to individual institution's policy for administration.* Pain is associated with peripheral infusion; administer via central vein whenever possible. Recommended maximum concentration for peripheral administration is 10 mEq/100 mL or 40 mEq/1000 mL; maximum infusion rate for adults with serum K^+ >2.5 mEq/L is 10 mEq/h or 200 mEq/24 h. Rates higher than 10 mEq/h require continuous ECG monitoring and serum K^+ level determination. For urgent use or if serum K^+ is <2 mEq/L, infusion rates up to 40/mEq/h or 400 mEq/d are admissible with continuous ECG monitoring and frequent serum K^+ level measurements.
- Administration via central venous access device: Preferred route for patients with severe hypokalemia. Recommended infusion rate is 10 to 20 mEq/h, except for emergencies and patients with severe hypokalemia.
- Potassium chloride should be diluted in saline solution, not dextrose, for administration. Dextrose solutions stimulate insulin release, which will cause extracellular K^+ to shift into cells, reducing already low K^+ levels.

*Potassium chloride concentrate for injection is an ISMP High-Alert medication. Potassium chloride injection has been removed from general floor stock on noncritical care units in most U.S. hospitals as a result of recommendations from the ISMP and Institute for Healthcare Improvement. Despite the limited access, errors involving administration of IV KCl still occur. To reduce errors, the following precautions should be followed: KCl vials should not be stocked on nursing units. The pharmacy should prepare admixtures prior to dispensing to patient-care units or dispense only premixed solutions to reduce the risk of patients receiving undiluted potassium. Never add KCl to an existing IV infusion.

TABLE 16-6 POTASSIUM SUPPLEMENTS

PREPARATION	DRUG
Oral liquid	Potassium chloride: 10% = 20 mEq/15 mL, 20% = 40 mEq/15 mL (Kay Ciel, Kaochlor 10%, Kaon-Cl 20%)
Oral tablet or capsule	Potassium chloride: enteric-coated tablet (Kaon, Kaon-Cl, Slow-K, 8 mEq Kaochlor, K-Lyte, effervescent tablet K-Lyte/Cl, K-Dur, Micro-K, Ten-K, K-Tab)
Intravenous potassium	Potassium chloride in clear liquid in multidose vial or ampule (2 mEq/mL)

Hyperkalemia

Hyperkalemia is defined as a serum potassium level >5.3 mEq/L; causes include excessive intake, decreased excretion, or shift from intracellular to extracellular space. The most common causes are renal failure and medications that interfere with potassium excretion. Renal disease or kidney failure results in potassium accumulating in the intravascular fluid and hyperkalemia. Persons at risk for developing hyperkalemia include premature infants, older adults, and those with a history of genitourinary disease, adrenal insufficiency, cancer, poorly controlled diabetes, or polypharmacy. Hyperkalemia manifests primarily as cardiac and neuromuscular symptoms. Signs and symptoms include cardiac dysrhythmias, including characteristic ECG changes—early tachycardia followed by bradycardia; paresthesias of face, tongue, hands, and feet; and GI hyperactivity, including nausea, diarrhea, and abdominal cramping. Metabolic acidosis may also be present.

Management goals are to eliminate the cause of the excess, shift potassium back into the cells, increase potassium excretion, decrease potassium intake, and prevent further episodes of hyperkalemia. For mild hyperkalemia, foods rich in potassium are usually restricted. Treatment strategies for hyperkalemia are outlined in Box 16-2.

PROTOTYPE DRUG CHART 16-1

Potassium

Drug Class
Electrolyte
Trade Names: Kaochlor, Kaon Cl, Kay Ciel, Micro K, K Dur
Pregnancy Category: A

Dosage
A: Prevention of hypokalemia: 20 mEq daily in 1-2 divided doses.
A: Replacement: 40 to 100 mEq daily in divided doses
A: IV: 10-60 mEq/100 mL of solution; *max:* 200-400 mEq/d; doses >10 mEq/h require continuous ECG monitoring

Contraindications
Renal insufficiency or failure, Addison's disease, hyperkalemia, severe dehydration, acidosis, potassium-sparing diuretics

Drug-Lab-Food Interactions
Drug: Increases serum potassium levels: ACE inhibitors, potassium-sparing diuretics, NSAIDs, beta-adrenergic blockers, heparin, salt substitutes. Decreases serum potassium levels: thiazide and loop diuretics, amphotericin B, antacids, insulin, fluconazole, theophylline, and laxatives
Caution: Cardiac and renal disease, burns
Food: Excessive intake of licorice may cause hypokalemia and sodium retention; salt substitutes contain potassium

Pharmacokinetics
Absorption: PO: rapidly absorbed, 95% in body fluids
Distribution: PB: UK
Metabolism: t½: UK
Excretion: 80%-90% in urine; 10% in feces

Pharmacodynamics
PO: Onset: 30 min
Peak: 1-2 h
Duration: UK
IV: Onset: Rapid
Peak: 1-1.5 h
Duration: UK

Therapeutic Effects/Uses
To correct potassium deficit; strengthen cardiac and muscular activities; prevent hypokalemia in at-risk patients; treat hypokalemic alkalosis.
Mode of Action: Transmits and conducts nerve impulses; contracts skeletal, smooth, and cardiac muscles.

Side Effects
Nausea, vomiting, diarrhea, abdominal cramps, irritability, rash (rare); phlebitis with IV administration

Adverse Reactions
Hyperkalemia (older adults with renal impairment); oliguria, ECG changes (peaked T waves, widened QRS complex, prolonged PR interval), GI ulceration
Life-threatening: Cardiac dysrhythmias, respiratory distress, ventricular fibrillation, cardiac arrest

A, Adult; *ACE,* angiotensin-converting enzyme; *ECG,* electrocardiogram; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *PB,* protein-binding; *PO,* by mouth; *t ½,* half-life; *UK,* unknown; *>,* greater than.

BOX 16-2 HYPERKALEMIA: TREATMENTS AND RATIONALES

Potassium Restriction

- Restriction of potassium intake will slowly lower serum level.
- For mild hyperkalemia (slightly elevated K^+ levels) (5.4 to 5.6 mEq/L, potassium restriction is normally effective).

Intravenous Sodium Bicarbonate

- By elevating pH level, potassium moves back into cells and lowers serum level.
- Temporary treatment

10% Calcium Gluconate

- Decreases irritability of myocardium resulting from hyperkalemia.
- Temporary treatment; does not promote K^+ loss.
- Caution: Administering to patient on digitalis can cause digitalis toxicity.

Insulin and Glucose (10%-50%)

- Moves potassium back into cells.
- Temporary treatment; effective for approximately 6 hours and not always as effective when repeated.

Kayexalate (Sodium Polystyrene) and Sorbitol 70%

- Kayexalate is used as a cation exchange for severe hyperkalemia; may cause hypocalcemia and hypomagnesemia and sodium retention.
- Can be administered orally or rectally.
- Approximate dosages:

Oral Administration

- Kayexalate: 10-20 g, 3-4 times daily
- Sorbitol 70%: 20 mL with each dose

Rectal Administration

- Kayexalate: 30-50 g as warm emulsion, enema given high into sigmoid colon
- Sorbitol 70%: 50 mL; mix with 100-150 mL of water

Constipation is a common adverse effect; assess bowel function daily; monitor for fecal impaction. A mild laxative may be prescribed.

Effect of Drugs on Potassium Balance

Potassium-wasting diuretics are a major cause of hypokalemia. Diuretics are divided into two categories: potassium-wasting (kaliuretic) and potassium-sparing (antikaliuretic) drugs. Potassium-wasting diuretics excrete potassium and other electrolytes such as sodium and chloride in the urine. Potassium-sparing diuretics retain potassium but excrete sodium and chloride in the urine.

Laxatives, corticosteroids, antibiotics, and potassium-wasting diuretics are the major drug classifications that can cause hypokalemia. Other drug classifications that may cause hyperkalemia include oral and IV potassium salts, central nervous system (CNS) agents, and potassium-sparing diuretics. Tables 16-7 and 16-8 list drugs that affect potassium balance.

Nursing Process

Patient-Centered Collaborative Care

Potassium

Assessment

- Assess for signs and symptoms of potassium imbalance. Symptoms of hypokalemia include nausea, vomiting, polyuria, cardiac dysrhythmias, abdominal distention, and soft, flabby muscles. Symptoms of hyperkalemia include oliguria, nausea, abdominal cramps, tachycardia and later bradycardia, weakness, and numbness or tingling in the extremities.
- Assess serum potassium level; normal level is 3.5 to 5.3 mEq/L. Report serum potassium deficit or excess to the health care provider.
- Obtain baseline vital signs and ECG readings. Report abnormal findings. Vital signs and ECG results can be compared with future readings.
- Check patient for signs and symptoms of digitalis toxicity when receiving a digitalis preparation and a potassium-wasting diuretic or a cortisone preparation. Decreased serum potassium level enhances the action

TABLE 16-7 DRUGS CAUSING HYPOKALEMIA

SUBSTANCES	RATIONALE
Laxatives	Abuse can cause potassium depletion.
Enemas (hyperosmolar)	
Corticosteroids	
Cortisone	Ion-exchange agent
Prednisone	Steroids promote potassium loss and sodium retention.
Kayexalate	Exchanges potassium ion for a sodium ion.
Levodopa/L-dopalithium	Increase potassium loss via urine.
Antibiotic I: amphotericin B, polymyxin B, gentamicin, neomycin, amikacin, tobramycin, cisplatin	Have a toxic effect on renal tubules and thus decrease potassium reabsorption.
Antibiotic II: penicillin, ampicillin, carbenicillin, ticarcillin, nafcillin, piperacillin, azlocillin	Enhance potassium excretion by the presence of nonabsorbable anions.
Alpha-adrenergic blockers	Promote movement of potassium into cells, thus lowering the serum potassium level.
Insulin and glucose	
Beta$_2$-agonists: terbutaline, albuterol	Promote potassium loss.
Estrogen	

TABLE 16-8 DRUGS CAUSING HYPERKALEMIA

SUBSTANCES	RATIONALE
potassium chloride (oral or IV)	Excess ingestion or infusion can cause potassium excess.
potassium salt substitutes	
potassium penicillin (pen-vee K)	
KPO_4 enema	
Angiotensin-converting enzyme inhibitors: captopril (Capoten), quinapril HCl (Accupril), ramipril (Altace)	Increase the state of hypoaldosteronism (decrease sodium and increase potassium) and impair renal potassium excretion.
Angiotensin II receptor antagonists	Decrease adrenal synthesis of aldosterone; potassium is retained and sodium is excreted.
Losartan potassium (Cozaar)	
Beta-adrenergic blockers: propranolol (Inderal), nadolol (Corgard)	Decrease cellular uptake of potassium, and decrease Na-K-ATPase function.
Digoxin	Therapeutic dose is not affected; however, with overdose, potassium excess may occur.
Heparin	Inhibits adrenal aldosterone production.
Low–molecular-weight heparin	Suppresses aldosterone
	Decreases potassium homeostasis; renal excretion of potassium is reduced.
Immunosuppressive drugs: cyclosporine, tacrolimus, cyclophosphamide	Reduce potassium excretion by induction of hypoaldosteronism; loss of potassium from cells.
Nonsteroidal antiinflammatory drugs: ibuprofen, indomethacin	Impair potassium homeostasis and block cellular potassium uptake.
Succinylcholine	Allows for leakage of potassium out of cells.
CNS agents: barbiturates, sedatives, opioids, heroin, amphetamines	Usually characterized by muscle necrosis and cellular shift of potassium from cells to serum.

of digitalis, increasing the likelihood of digitalis toxicity. Signs and symptoms of digitalis toxicity are nausea, vomiting, anorexia, bradycardia (pulse rate <60 or markedly decreased), cardiac dysrhythmias, and visual disturbances.

Nursing Diagnoses

- Deficient knowledge related to inadequate knowledge of medications and foods affecting potassium levels
- Risk for decreased cardiac output related to excess serum potassium
- Activity intolerance related to muscle weakness

Planning

- Patient's serum potassium level will be within normal range.
- Patient will verbalize understanding of the potassium imbalance and state methods to decrease recurrence. Patient with hypokalemia will eat potassium-rich foods. Patient with hyperkalemia will avoid potassium-rich foods.

Nursing Interventions

- Give oral potassium with sufficient amount of water or juice (at least 3 to 8 oz) and with meals. Potassium is extremely irritating to the gastric mucosa.
- Hang IV solutions containing potassium to be infused only with an infusion-control device; monitor infusion at least hourly.
- Potassium cannot be given intramuscularly. Potassium should never be given as an IV bolus or push. Giving IV potassium directly into the vein causes cardiac dysrhythmias and cardiac arrest.
- Check amount of urine output. Potassium accumulation occurs if patient is receiving potassium and urine output is <25 mL/h or <600 mL/d. Remember: 80% to 90% of potassium is excreted in the urine. Report results to the health care provider.
- Monitor serial potassium levels frequently as well as serum creatinine, BUN, glucose, electrolytes, and arterial blood gases. Report abnormal results to health care provider.
- Monitor ECG. With hypokalemia, there is a flat or inverted T wave, a depressed ST segment, and a prolonged QT interval. With hyperkalemia, there is a narrow and peaked T wave, widened QRS complex, prolonged PR interval, flattened or absent T waves, and depressed ST segment.
- Monitor patient's response to activity, and plan frequent rest periods due to muscle weakness associated with potassium imbalances.
- Check IV site for infiltration if patient is receiving IV potassium. Potassium can cause extravasation and tissue necrosis if it infiltrates into subcutaneous tissue. Discontinue IV immediately if infiltration occurs.
- Monitor patients receiving medications for hyperkalemia for signs and symptoms of continuing hyperkalemia or iatrogenic hypokalemia.

Patient Teaching

General

- Advise patient to have serum potassium level checked at regular intervals as prescribed by primary health care provider when taking medications that affect potassium levels.
- Instruct patient to drink a full glass of water or juice when taking oral potassium supplements. Potassium preparations can be taken during or after a meal. Explain to patient that potassium is very irritating to the stomach.
- Encourage patient to comply with prescribed potassium dose, regular laboratory tests, and medical follow-up related to the health problem and drug regimen.
- Instruct patient to report signs and symptoms of hypokalemia and hyperkalemia.

Diet

- Instruct patients who are taking medications promoting potassium loss to eat potassium-rich foods.
- Instruct patients at risk for potassium imbalances regarding dietary sources of potassium and potassium content of foods.

Cultural Considerations

- Use an interpreter as appropriate.
- Involve the extended family in health teaching and support.
- Incorporate food choices that are culturally acceptable.

Evaluation

- Evaluate patient's serum potassium level and ECG. Cardiac rhythm should return to patient's normal baseline without dysrhythmias. Serum potassium level remains within normal range. Report to the health care provider if the level remains abnormal. Potassium replacements and diet may need modification.

Sodium

Sodium is the major cation in the ECF. The normal serum or plasma sodium level is 135 to 145 mEq/L. A serum sodium level <135 mEq/L is called **hyponatremia,** and a serum sodium level >145 mEq/L is called **hypernatremia.** Sodium and chloride imbalances typically occur together. The most serious problems associated with serum sodium deficit or excess are cerebral dehydration, seizures, and coma.

The dietary requirement for sodium is 2 to 4 g/d. Sodium-rich foods include bacon, luncheon meats, corned beef, decaffeinated coffee, ham, tomato juice, pickles, and soda crackers.

Functions

Sodium is found in most body fluids, plays a major role in fluid volume balance, and is the primary determinant of plasma osmolality. Sodium combines readily with chloride (Cl^-) or bicarbonate (HCO_3^-) to promote acid-base balance. Sodium promotes the transmission and conduction of nerve impulses and is part of the sodium/potassium pump. There is rapid sodium influx into cells during depolarization as potassium shifts out of cells to maintain water balance and neuromuscular activity. When sodium shifts into the cell, depolarization occurs. Repolarization of the cell occurs when the cell membrane is primarily permeable to potassium with the shift of potassium out of the cell due to the diffusion gradient. Sodium imbalance is usually accompanied by water imbalance due to its effects on fluid volume balance.

Hyponatremia

Hyponatremia is caused by sodium loss, deficient intake, or water gain. Sodium loss can result from vomiting, diarrhea, nasogastric suctioning, burns, wound drainage, trauma, renal failure, heart failure, third-spacing, syndrome of inappropriate antidiuretic hormone secretion, excessive hypertonic or sodium-free IVF, surgery, and thiazide diuretics. Hyponatremia may occur with hypovolemia and hypervolemia. Presenting symptoms depend on the onset and degree of deficit. Signs and symptoms of hyponatremia due to water shifting into cells are primarily neuromuscular and GI and include muscle weakness; decreased deep tendon reflexes; headaches; lethargy; confusion; seizures; coma; abdominal cramps; nausea and vomiting; tachycardia and hypotension; pale skin; and dry mucous membranes. Signs of hyponatremia associated with decreased ECF (hypovolemia) include tachycardia; weak, thready pulse; and decreased blood pressure progressing to orthostatic hypotension. If hyponatremia is caused by increased ECF (hypervolemia), signs and symptoms include jugular vein distention, weight gain, edema, and increased blood pressure.

Oral sodium replacement is the preferred treatment if the patient is able or if the deficit is mild. Sodium may also be replaced via enteral feeding tubes. For a serum sodium level between 125 and 135 mEq/L, IV normal saline (0.9% sodium chloride) may increase sodium content in vascular fluid. For a serum sodium level <120 mEq/L, a hypertonic 3% or 5% saline solution may be necessary.

Hypernatremia

Hypernatremia can be caused by sodium gain, sodium retention, or water loss. Causes include excessive oral sodium intake, deficient water intake, hypertonic tube feedings, hypertonic IVF, hyperaldosteronism, Cushing's syndrome, corticosteroid use, and acute kidney failure. Other causes include vomiting, diarrhea, burns, diabetes insipidus, and mineralocorticoid excess.

Signs of fluid imbalance depend on the cause; water loss presents with symptoms of FVD, while sodium gain presents with symptoms of FVE. Signs and symptoms of hypernatremia are dry, sticky mucous membranes; flushed, dry skin; agitation; elevated body temperature; rough, edematous, dry tongue; nausea and vomiting; anorexia; tachycardia; hypertension; muscle twitching; hyperreflexia; seizures; and coma. Thirst is usually the first symptom of sodium deficit.

Management of hypernatremia depends on the cause and severity of the deficit. Frequent monitoring of sodium levels is necessary while the underlying cause is being treated. When the serum sodium level is elevated >145 mEq/L, sodium restriction is indicated. Treatments include administration of IVF and diuretics.

Nursing Process
Patient-Centered Collaborative Care

Sodium

Assessment

- Assess patient for signs and symptoms of sodium imbalance. Symptoms of hyponatremia are muscle weakness, headaches, lethargy, confusion, seizures, abdominal cramps, nausea and vomiting, tachycardia and hypotension, pale skin, and dry mucous membranes. Symptoms of hypernatremia are flushed, dry skin; agitation; elevated body temperature; rough, dry tongue; nausea and vomiting; anorexia; tachycardia; hypertension; muscle twitching; and hyperreflexia.
- Check serum sodium level. Report abnormally low sodium levels (<125 mEq/L), because prompt medical care is required.
- Obtain history of health problems that may lead to sodium loss or excess.

Nursing Diagnoses

- Risk for imbalanced (excess) fluid volume related to water retention
- Readiness to learn about sodium-rich foods

Planning

- Patient's serum sodium level will be within normal range in 3 to 5 days.
- Edema will be decreased in patient with sodium retention.

Nursing Interventions

- Monitor prescribed medical regimen for correction of hyponatremia—for example, water restriction, IV normal saline (0.9% sodium chloride), or 3% saline solution to correct serum sodium levels <115 mEq/L.
- Monitor serum sodium levels. Report abnormal levels.

Patient Teaching

- Instruct patient with hypernatremia to avoid foods high in sodium. Instruct patient to avoid using salt when cooking and adding salt to food at the table.

- Emphasize importance of reading labels on food products.

Cultural Considerations

- Use interpreter as appropriate.
- Involve extended family in health teaching and support.
- Incorporate food choices that are culturally acceptable.

Evaluation

- Evaluate patient's serum sodium level. Report if sodium imbalance continues.
- Assess patient's fluid volume balance. Monitor intake and output carefully; monitor daily weights.
- Assess patient for signs of circulatory overload and deficit.

Calcium

Calcium is found in approximately equal proportions in ICF and ECF. The serum calcium range is 4.5 to 5.5 mEq/L, or 8.5 to 10.5 mg/dL. A calcium deficit (<4.5 mEq/L) is called **hypocalcemia,** and a calcium excess (>5.5 mEq/L) is called **hypercalcemia.** Over 90% of the body's calcium is found in bones and teeth. Of the remaining calcium found in the blood, about 50% is bound to protein, primarily albumin. The remaining 50% is free, ionized calcium (iCa) and can leave the vascular space and be active in cellular functions. Serum levels are measures of both ionized and protein-bound calcium.

The normal serum iCa range is 2.2 to 2.5 mEq/L, or 4.25 to 5.25 mg/dL. Calcium levels are affected by acid-base balance and plasma albumin levels. When an individual is acidotic, calcium is released from serum protein, which increases serum iCa level. During alkalosis, calcium is bound to protein, and there is less iCa. If serum albumin levels are decreased, there is more free circulating calcium, even when the serum calcium level is decreased. There are formulas to correct the serum calcium levels in patients with hypoalbuminemia.

Functions

Calcium promotes normal nerve and muscle contraction and plays a role in cardiac excitability. This cation also maintains normal cellular permeability and promotes blood clotting by converting prothrombin into thrombin. Calcium is also needed for formation of bone and teeth. Calcium levels are regulated by parathyroid hormone and calcitonin. Calcium functions are closely related to magnesium and phosphorus. Calcium and phosphorus have an inverse relationship; that is, increased calcium levels result in decreased phosphorus levels.

Vitamin D is needed for calcium absorption from the GI tract. Aspirin and anticonvulsants can alter vitamin D, affecting calcium absorption. Loop or high-ceiling diuretics (see Chapter 43), steroids (cortisone), magnesium preparations, and phosphate preparations promote calcium loss. Conversely, thiazide diuretics increase serum calcium levels.

Hypocalcemia

Inadequate calcium intake causes calcium to leave bone to maintain a normal serum calcium level. Because of calcium loss from bones (bone demineralization), pathological fractures may occur if calcium deficit persists. Hyperphosphatemia, acute pancreatitis, widespread bony metastases, hypoparathyroidism, alkalosis, diarrhea, alcoholism, malnutrition, use of loop diuretics, vitamin D deficiency, and multiple blood transfusions are common causes of hypocalcemia.

Signs and symptoms of hypocalcemia reflect calcium's role in nerve transmission and heart and muscle function. Neurologic and neuromuscular symptoms include anxiety, irritability, and tetany; twitching; hyperactive deep tendon reflexes; carpopedal spasm; spasmodic contractions; laryngeal spasm; and seizures. Positive Chvostek's and Trousseau's signs are classic signs of hypocalcemia associated with tetany. Cardiovascular manifestations include decreased cardiac output; dysrhythmias; and ECG changes including prolonged QT interval, elongated ST segment, and ventricular tachycardia (torsades de pointes). Hypocalcemia also causes a diminished response to digitalis; other signs are dry, brittle nails and dry hair and skin.

If metabolic acidosis is present with hypocalcemia, tetany symptoms are absent because calcium leaves protein sites during an acidotic state; thus, more iCa is available. During an alkalotic state, more calcium binds with protein. There is less iCa, and tetany symptoms usually result.

Many calcium preparations can be administered orally or IV. The treatment depends on the cause, degree of deficit, and clinical condition of the patient. IV calcium replacement should be administered only to acutely symptomatic patients. Oral calcium preparations are available in tablets, capsules, and powders. Calcium preparations are combined with various salts such as chloride, carbonate, gluconate, gluceptate, and lactate. IV calcium is available as calcium chloride (CaCl) (10%) and calcium gluconate (10%); both can be used for acute hypocalcemia and during cardiac resuscitation. Calcium gluconate may be given subcutaneously or intramuscularly. Both preparations deliver 20 mg of elemental calcium per mEq. Calcium gluconate has the same action on the heart as digitalis: it increases the force of systolic contractions. Prototype Drug Chart 16-2 describes the pharmacokinetics and pharmacodynamics of calcium preparations.

The patient's renal functioning should be assessed before administering IV CaCl; this solution contains aluminum, which can be toxic if renal insufficiency exists. IV calcium should be administered cautiously in patients who take digitalis because an increase in serum calcium increases the risk of digitalis toxicity. Concentrated calcium solutions (10% CaCl) require a central line for administration. The solution should be administered slowly via an infusion-control device,

PROTOTYPE DRUG CHART 16-2

Calcium

Drug Class Electrolyte Pregnancy Category: C Drug Forms: Tablet, capsule, liquid, injection	**Dosage** Tetany: A: IV: 4-16 mEq C: IV: 0.5-0.7 mEq/kg t.i.d., q.i.d. Hypocalcemia: A: PO: 500 mg/d in divided doses
Contraindications Hypercalcemia, renal calculi, digitalis toxicity, ventricular fibrillation Caution: Renal insufficiency, renal stones, dehydration, diarrhea, respiratory acidosis, or respiratory failure	**Drug-Lab-Food Interactions** Drug: Increase digitalis toxicity: digoxin; decrease calcium channel blockers, verapamil; decrease absorption of tetracycline; increase serum calcium level: thiazide diuretics Lab: May increase gastrin, pH; may decrease phosphate, potassium
Pharmacokinetics Absorption: PO: 35% absorbed, requires vitamin D Distribution: PB: UK Metabolism: t½: UK Excretion: 20% in urine, 70% in feces, some in saliva	**Pharmacodynamics** PO: Onset: UK Peak: UK Duration: 2-4 h IV: Onset: Rapid Peak: UK Duration: 2-3 h
Therapeutic Effects/Uses To correct calcium deficit or tetany symptoms, prevent osteoporosis Mode of Action: Transmits nerve impulses, contracts skeletal and cardiac muscles, maintains cellular permeability; promotes strong bone and teeth growth	
Side Effects PO: Nausea, vomiting, constipation, pain, drowsiness, headache, muscle weakness	**Adverse Reactions** Hypercalcemia, ECG changes (shortened QT interval), metabolic alkalosis, heart block, rebound hyperacidity Life-threatening: Renal failure, cardiac dysrhythmias, cardiac arrest

A, Adult; *C,* child; *d,* day; *ECG,* electrocardiogram; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *PB,* protein binding; *PO,* by mouth; *q.i.d.,* four times a day; *t ½,* half-life; *t.i.d.,* three times a day; *UK,* unknown.

and the patient should be monitored frequently. Too rapid an infusion may cause cardiac syncope and decreased blood pressure from peripheral vasodilation. Use of a small-bore needle in a large vein minimizes venous irritation. The patient may report a burning sensation with higher infusion rates. It is essential to ascertain that the IV is in the vein and not infiltrated. Local extravasation may cause tissue necrosis and sloughing. Refer to agency policy if infiltration occurs.

Patients with hypocalcemia should be assessed for hypomagnesemia, hypokalemia, and acid-base imbalances, and any abnormalities should be corrected. Hypomagnesemia should be corrected first; low magnesium levels may render the patient refractory to treatment for hypocalcemia.

Pharmacokinetics Vitamin D promotes calcium absorption from the GI tract; phosphorus inhibits calcium absorption. The pH affects the amount of free iCa. When pH is decreased (acidic), there is more free iCa, because it has been released from protein-binding sites. With an increased pH (alkalosis), more calcium is bound to protein.

Hypercalcemia

Elevated serum calcium may be a result of hyperparathyroidism, malignancy, hypophosphatemia, excessive calcium intake, prolonged immobilization, multiple fractures, and drugs such as thiazide diuretics and steroids. Signs and symptoms of hypercalcemia are fatigue, muscle weakness, depressed deep tendon reflexes, confusion, impaired memory, anorexia, nausea, vomiting, constipation, and kidney stones of calcium composition. ECG changes include shortened QT interval and ST segment; the patient may exhibit decreased heart rate and dysrhythmias.

Effect of Drugs on Calcium Balance

Phosphate preparations, corticosteroids, loop diuretics, aspirin, anticonvulsants, magnesium sulfate, and mithramycin are some of the drug groups that can lower serum calcium levels. Excess calcium salt ingestion or infusion and thiazide and chlorthalidone diuretics can all contribute to an increased serum calcium level. Table 16-9 lists drugs that affect calcium balance.

Clinical Management of Calcium Imbalance

Clinical management of hypocalcemia consists of oral supplements and IV calcium. Table 16-10 lists oral and IV preparations of calcium salts, their dosages, and drug forms. Calcium carbonate can cause GI upset because it produces carbon dioxide. For better calcium absorption, calcium supplements should contain vitamin D, and oral calcium should be taken 30 minutes before meals.

TABLE 16-9 DRUGS AFFECTING CALCIUM BALANCE

SUBSTANCES	RATIONALE
Drugs Causing Hypocalcemia	
Magnesium sulfate	Inhibit parathyroid hormone/PTH secretion and decrease serum calcium level.
Propylthiouracil (Propacil)	
Colchicine	
Plicamycin (Mithracin)	
Neomycin	
Excessive sodium citrate	
Acetazolamide	Can alter vitamin D metabolism needed for calcium absorption.
Aspirin	
Anticonvulsants	
Glutethimide (doriden)	
Estrogens	
Aminoglycosides: gentamicin, amikacin, tobramycin	
Phosphate preparations: oral, enema, intravenous; sodium phosphate; potassium phosphate	Can increase serum phosphorus level and decrease serum calcium level.
Corticosteroids: cortisone, prednisone	Decrease calcium mobilization and inhibit calcium absorption.
Loop diuretics: furosemide (Lasix)	Reduce calcium absorption from renal tubules.
Drugs Causing Hypercalcemia	
Calcium salts	Excess ingestion of calcium and vitamin D and infusion of calcium can increase serum calcium level.
Vitamin D	
IV lipids	Can increase serum calcium level.
Androgens	Can induce hypercalcemia.
Diuretics: thiazides, chlorthalidone (Hygroton)	
Lithium	Increases parathyroid hormone/PTH secretion.

TABLE 16-10 CALCIUM PREPARATIONS

CALCIUM NAME	DRUG FORM	DRUG DOSE
Orals		
calcium carbonate	650- to 1500-mg tablets	400 mg/g*
calcium citrate	950-mg tablet	211 mg/g*
calcium gluconate	500- to 1000-mg tablets	90 mg/g*
Intravenous		
calcium chloride	10 mL	272 mg/g*; 13.5 mEq
calcium gluconate	10 mL	90 mg/g*; 4.5 mEq

*Elemental calcium is 1 g.

The goal for managing hypercalcemia is to correct the underlying cause of serum calcium excess. Drugs such as calcitonin or IV saline solution administered rapidly and followed by a loop diuretic can be used to promote rapid urinary excretion of calcium.

Nursing Process
Patient-Centered Collaborative Care

Calcium

Assessment

- Assess patient for signs and symptoms of calcium imbalance. Signs and symptoms of hypocalcemia are tetany, muscle cramps, bleeding tendencies, and weak cardiac contractions. Signs and symptoms of hypercalcemia are flabby muscles, pain over bony areas, and kidney stones of calcium composition.
- Assess for Trousseau's sign (muscular spasm of hand and wrist when pressure applied to vessels and nerves of upper arm) and Chvostek's sign (spasm of facial muscles resulting from tap on facial nerve).
- Check serum calcium levels. Report abnormal test results. Serum iCa (normal: 2.2 to 2.5 mEq/L or 4.25 to 5.25 mg/dL) indicates free, circulating calcium and is more accurate for determining calcium imbalance.
- Assess for albumin levels, and correct for serum calcium level.
- Obtain vital signs and ECG readings. Report abnormal findings. Vital signs and ECG results can be compared with future readings.
- Gather current drug history for patient. Calcium enhances the effect of digoxin. Elevated serum calcium level can cause digitalis toxicity. Signs and symptoms of digitalis toxicity include nausea, vomiting, anorexia, bradycardia (pulse rate <60 or markedly decreased), cardiac dysrhythmias, and visual disturbances. Thiazide diuretics can increase the serum calcium level. Drugs that decrease the effect of calcium are calcium channel blockers, tetracycline, and sodium chloride.

Nursing Diagnoses

- Imbalanced nutrition less than body requirements related to GI discomfort
- Impaired tissue integrity related to numbness and tingling of hands
- Readiness to learn about calcium-rich foods

Planning

- Patient's serum calcium level will be within normal range.
- Tetany symptoms will cease. Patient will eat calcium-rich foods or take calcium supplements as ordered.
- Patient with hypercalcemia will avoid calcium-rich foods.

Nursing Interventions

- Monitor vital signs. Report abnormal findings. Compare with baseline vital signs. Monitor pulse rate if patient is taking digoxin. Bradycardia is a sign of digitalis toxicity.

- Administer IVFs slowly with 10% calcium gluconate or chloride. Calcium should not be added to solutions containing bicarbonate, because rapid precipitation occurs.
- Check IV site for infiltration if patient is receiving calcium in IVFs. Calcium can cause tissue necrosis and sloughing if it infiltrates into subcutaneous tissue. CaCl preparations should be administered through a central line only. Calcium gluceptate is the only calcium preparation that can be given IM.
- Monitor serum calcium and iCa levels.
- Monitor ECGs. With hypocalcemia, ST segment is lengthened and QT interval is prolonged. With hypercalcemia, ST segment is decreased and QT interval is shortened.

Patient Teaching

General

- Instruct patient to avoid overuse of antacids and chronic use of laxatives. Overuse of certain antacids may cause alkalosis, decreasing calcium ionization. Chronic use of laxatives decreases calcium absorption from the GI tract. Suggest high-fiber foods for improving bowel elimination.
- Encourage patient taking calcium supplements to check that the calcium tablet is absorbable. To do this, put one tablet into 1 oz of white vinegar. Stir every 3 minutes. The tablet should break up or dissolve within 30 minutes.
- Advise patient to take oral calcium supplements with meals or after meals to increase absorption.

Diet

- Suggest that patient consume high-calcium foods such as milk and dairy products. Protein and vitamin D are needed to enhance calcium absorption.
- Side Effects
- Instruct patient to report symptoms related to calcium excess or hypercalcemia, including muscle weakness, pain over bony areas, ECG changes, and renal (calcium composition) stones.

Cultural Considerations

- Use an interpreter as appropriate.
- Involve extended family in health teaching and support.
- Incorporate food choices that are culturally acceptable.

Evaluation

- Evaluate patient's serum calcium and electrolyte levels. Report if calcium imbalance continues.
- Monitor patient for neuromuscular and cardiac manifestations of calcium imbalance.

Magnesium

Magnesium is most plentiful in the ICF. Magnesium deficit often occurs with hypokalemia and hypocalcemia. Normal serum magnesium level is 1.5 to 2.5 mEq/L or 1.8 to 3 mg/dL. Magnesium deficit is called **hypomagnesemia,** and magnesium excess is called **hypermagnesemia.** Daily magnesium requirement is 8 to 20 mEq.

Functions

Magnesium promotes transmission of neuromuscular activity; it is an important mediator of neural transmission in the CNS. Like potassium, it promotes contraction of the myocardium. Magnesium activates many enzymes for metabolism of carbohydrates and protein and is responsible for transportation of sodium and potassium across cell membranes.

Serum magnesium deficit increases the release of acetylcholine from the presynaptic membrane of the nerve fiber, which increases neuromuscular excitability. Serum magnesium excess has a sedative effect on the neuromuscular system, which can result in loss of deep tendon reflexes. Cardiac (ventricular) dysrhythmias, hypotension, and heart block can occur as a result of hypomagnesemia.

Hypomagnesemia is probably the most undiagnosed electrolyte deficiency. This is most likely because hypomagnesemia is asymptomatic until the serum magnesium level approaches 1 mEq/L. Total serum magnesium concentration is not representative of the cellular magnesium levels.

To correct severe hypomagnesemia, IV magnesium sulfate is usually given. For hypermagnesemia, calcium gluconate may be given to decrease the serum magnesium level.

Effect of Drugs on Magnesium Balance

Sodium inhibits tubular absorption of magnesium and calcium. Long-term administration of saline infusions may result in losses of magnesium and calcium. Diuretics, certain antibiotics, laxatives, and steroids are drug groups that promote magnesium loss. Hypomagnesemia, like hypokalemia, enhances the action of digitalis and causes digitalis toxicity.

Magnesium sulfate corrects hypomagnesemia and symptoms of digitalis toxicity. It is common practice after bypass surgery or myocardial infarction for patients to be given magnesium sulfate orally, even when blood levels are normal, to prevent ventricular arrhythmias in the perioperative period.

Excess intake of magnesium salts is the major cause of serum magnesium excess. Commonly used medications that may cause hypermagnesemia include laxatives and antacids. Patient teaching regarding prolonged or frequent use of laxatives, particularly in older adults, is an important intervention in preventing electrolyte imbalance. Table 16-11 lists drugs that affect magnesium balance.

TABLE 16-11 DRUGS AFFECTING MAGNESIUM BALANCE

DRUGS	RATIONALE
Drugs Causing Hypomagnesemia	
Diuretics: furosemide (Lasix), ethacrynic acid (Edecrin), mannitol	Promote urinary loss of magnesium.
Antibiotics: gentamicin, tobramycin, carbenicillin, capreomycin, neomycin, polymyxin B, amphotericin B, digitalis, calcium gluconate, insulin	Can cause magnesium loss via kidney.
Laxatives: cisplatin	Abuse can cause magnesium loss via gastrointestinal tract.
Corticosteroids: cortisone, prednisone	Can decrease serum magnesium level.
Drugs Causing Hypermagnesemia	
Magnesium salts (Oral and enema: magnesium hydroxide [milk of magnesia]), magnesium sulfate (Epsom) salt, magnesium citrate, magnesium sulfate (maternity)	Excessive use can increase serum magnesium level. Use of excessive magnesium sulfate in treatment of toxemia can cause hypermagnesemia.
Lithium	Associated with hypermagnesemia.

Nursing Process
Patient-Centered Collaborative Care

Magnesium

Assessment

- Assess patient for signs and symptoms of magnesium imbalance. Signs and symptoms of hypomagnesemia are tetany-like symptoms caused by hyperexcitability (tremors, twitching of the face) and ventricular tachycardia that leads to ventricular fibrillation and hypertension. Signs and symptoms of hypermagnesemia are lethargy, drowsiness, weakness, paralysis, loss of deep tendon reflexes, hypotension, and heart block.
- Check serum magnesium levels for magnesium imbalance. Symptoms of magnesium deficit may not be seen until serum level is <1 mEq/L.
- Observe patients receiving digitalis preparations for digitalis toxicity. Magnesium deficit, like potassium deficit, enhances the action of digitalis, causing digitalis toxicity.

Nursing Diagnoses

- Imbalanced nutrition less than body requirements related to insufficient intake of magnesium-rich foods
- Decreased cardiac output related to hypomagnesemia or hypermagnesemia
- Readiness to learn about signs and symptoms of magnesium imbalance

Planning

- Patient's serum magnesium level will be within normal range.
- Patient will not experience life-threatening symptoms of magnesium imbalance.
- Patient will have normal serum electrolyte levels.

Nursing Interventions

- Report to health care provider if patient is NPO and receiving IVFs without magnesium salts for a prolonged period. Slowly administer IV magnesium sulfate in solution to prevent hot or flushed feeling. Monitor vital signs.
- Monitor urinary output. Most of the body's magnesium is excreted by the kidneys. Report if urine output is <600 mL/d.
- Monitor for digitalis toxicity (e.g., nausea, vomiting, bradycardia) in patients who have hypomagnesemia and are taking digoxin. Magnesium deficit enhances the action of digitalis preparations.
- Monitor vital signs. Report abnormal findings to health care provider.
- Monitor serum electrolyte results. Report low serum potassium or serum calcium levels. Low serum magnesium levels may be attributed to hypokalemia or hypocalcemia. When correcting a potassium deficit, potassium is not replaced in cells until magnesium is replaced. Serum magnesium level of 1 mEq/L or less can cause cardiac arrest.
- Check for Trousseau's and Chvostek's signs of severe hypomagnesemia. Tetany symptoms occur in both magnesium and calcium deficits.
- Have IV calcium gluconate available for emergency reversal of hypermagnesemia from overcorrection of a magnesium deficit.

Patient Teaching

- Advise patient with hypomagnesemia to eat foods rich in magnesium (green vegetables, fruits, fish, grains, nuts).
- Instruct patient with hypermagnesemia to avoid routine use of laxatives and antacids that contain magnesium. Suggest that patient check drug labels.

Cultural Considerations

- Use an interpreter as appropriate.
- Involve extended family in health teaching and support.
- Incorporate food choices that are culturally acceptable.

Evaluation

- Evaluate patient's serum magnesium level. Report if magnesium imbalance continues.
- Determine whether signs and symptoms caused by prior magnesium imbalance are absent.

Chloride

Chloride is the principal anion of ECF. The chloride ion is a major contributor to acid-base balance, gastric juice acidity, and the osmolality of ECF. Normal serum chloride level is 95 to 108 mEq/L. **Hypochloremia** is a decreased serum chloride level, and **hyperchloremia** is an elevated level. With increased serum osmolality (>300 mOsm/kg), there are more sodium and chloride ions proportional to the water. Sodium and chloride frequently work in combination. For example, during sodium retention, chloride is also frequently retained, resulting in increased water retention. Clinical manifestations of hypochloremia include tremors, twitching, and slow, shallow breathing. With severe chloride loss, decreased blood pressure is seen. Clinical manifestations of hyperchloremia include weakness; lethargy; deep, rapid breathing; and eventual unconsciousness.

Phosphorus

Phosphorus is found in both ICF and ECF but is the primary anion in ICF. Similar to calcium and magnesium, serum phosphorus levels are not reflective of the true concentration of the body's phosphorus. The majority of the body's phosphorus is found as phosphate; these two terms are used interchangeably.

Both phosphorus and calcium levels are regulated by parathyroid hormone (PTH) and need vitamin D for absorption from the GI tract. Serum phosphorus levels are decreased by PTH stimulation of the renal tubules to excrete phosphorus (and concomitantly increase serum calcium levels by causing calcium to leave bone). Normal serum phosphorus level is 1.7 to 2.6 mEq/L. Fifty-five percent is ionized (free), and 45% is protein bound.

Phosphorus is essential in bone and teeth formation and for neuromuscular activity. Phosphorus is an important component of nucleic acids (DNA and RNA) and assists in energy transfer in cells, helps maintain cellular osmotic pressure, and supports the acid-base balance of body fluids. Clinical manifestations of **hypophosphatemia** include muscle weakness, tremors, paresthesia, bone pain, hyporeflexia, seizures, hyperventilation, anorexia, and dysphagia. Symptoms of **hyperphosphatemia** are similar to those of hypocalcemia, including hyperreflexia, tetany, positive Chvostek's and Trousseau's signs, flaccid paralysis, muscular weakness, tachycardia, nausea, diarrhea, and abdominal cramps. Phosphorus-rich foods include whole-grain cereals, nuts, milk, and meat. Phosphorus deficiency can result from decreased intestinal absorption, malnutrition, alcoholism, vomiting, diarrhea, use of concentrated glucose solutions, respiratory alkalosis, glycosuria, hypokalemia, hypomagnesemia, or use of thiazide diuretics. Hypophosphatemia may lead to hemolytic anemia, platelet dysfunction, and reduced oxygen transport. Hyperphosphatemia is most often related to chronic kidney disease. Increased intake in the form of laxatives may also increase serum levels.

Treatment of phosphorus imbalance is aimed at eliminating or reducing the cause. Monitoring phosphorus, calcium, and magnesium levels and assessing the patient for signs of electrolyte and acid-base balance are important nursing interventions. Phosphorus replacement is guided by degree of deficit, onset, and patient presentation. Oral intake is the preferred route of replacement. IV phosphorus is available for treatment of patients who are unable to tolerate oral replacements or patients with severe deficits. Potassium phosphate is an Institute for Safe Medication Practices (ISMP) high-alert medication used for IV phosphorus replacement. Potassium phosphate must be diluted before use and infused slowly using an infusion-control device. Too-rapid infusion may cause potassium toxicity in patients with severe renal or adrenal insufficiency. The IV insertion site must be monitored for infiltration; potassium phosphate may cause tissue necrosis and sloughing if infiltration occurs. Phosphorus, potassium, and calcium levels and renal function should be monitored during and after infusion. Use of potassium phosphate is contraindicated in patients with hyperkalemia or hypocalcemia.

Hyperphosphatemia in patients with chronic kidney disease is treated with restriction of dietary phosphorus, phosphorus-binding medications such as calcium acetate (Phoslo), or dialysis. Hyperphosphatemia can lead to secondary hyperparathyroidism and osteodystrophy.

CRITICAL THINKING CASE STUDY

JS, 72 years of age, has had vomiting and diarrhea for 2 days. JS takes digoxin, 0.25 mg/d, and hydrochlorothiazide, 50 mg/d. His serum potassium level is 3.2 mEq/L. He complains of being dizzy. His blood pressure is slightly lower than usual. The nurse assesses his physiologic status and notes that his muscles are weak and flabby, his abdomen is distended, and peristalsis is diminished.

1. What signs and symptoms indicate that JS is in potassium imbalance?
2. What contributing factors caused JS's potassium imbalance?

3. What interventions should be performed for alleviating this potassium imbalance?
4. How much potassium chloride would be needed to elevate JS's serum potassium by 1 mEq?

JS is ordered IV infusions of 1 L of 5% dextrose in water with 30 mEq of potassium chloride (KCl) and 1 L of 5% dextrose in 0.45% NaCl (½ normal saline). He is also prescribed oral KCl 15 mEq, three times per day for 2 days. Oral KCl is available in 15 mEq/10 mL.

5. Explain the method for diluting KCl in IVFs. Can KCl be given intramuscularly, subcutaneously, or as an IV bolus (push)? Explain your answer.
6. What instructions should the nurse give JS for taking oral potassium supplements?
7. What happens if JS's urine output decreases while he is receiving IV and oral potassium? What would be the nurse's responsibility?
8. Because JS is taking a diuretic and digoxin, what should the nurse include with client teaching? Give examples.

NCLEX STUDY QUESTIONS

1. A patient is postoperative day 3 after a total colectomy and ileostomy. He has a nasogastric tube to continuous suction and a Foley catheter to continuous drainage. The night nurse reports a high output from the ileostomy. The patient's pulse is irregular, and he reports leg weakness. Based on this situation, the nurse would correctly suspect what type of imbalance?
   - a. Hypokalemia
   - b. Hyperkalemia
   - c. Hyponatremia
   - d. Hypercalcemia
2. A patient is receiving IV potassium supplements. What is the most important nursing implication when administering this drug?
   - a. IV potassium supplements may only be administered via a central vascular access device.
   - b. IV potassium must be diluted before administration.
   - c. IV potassium must be chilled before administration.
   - d. IV potassium preparations do not contain preservatives.
3. A patient is receiving 10 mEq of KCl in 100 mL of NS to infuse over 1 hour IVPB. The patient has a #22-gauge peripheral IV in his right forearm. The patient reports pain at the insertion site; the nurse notes that the site is reddened, warm, and tender to the touch. Which action would the nurse take?
   - a. Aspirate and check for blood return, and then slow the IV rate.
   - b. Discontinue the IV, and then have a central line inserted to administer the potassium.
   - c. Stop the infusion, and discontinue the IV immediately.
   - d. Apply warm compresses to the IV site.
4. The health care provider orders a hypertonic crystalloid IV solution for a 70-year-old patient with cerebral edema. Which assessment should the nurse report immediately to the provider?
   - a. Improved blood pressure, increased urinary output, and stable vital signs
   - b. Hyperglycemia, decreased urinary output, and increased level of consciousness
   - c. Thirst, dry mouth, cool extremities, and decreased urinary output
   - d. Headache, irritability, confusion, widening pulse pressure, and decreased level of consciousness
5. A patient is receiving fluid replacement. The nurse's health teaching with this patient includes which suggestions? (Select all that apply.)
   - a. Measure weight daily.
   - b. Know that thirst means a mild fluid deficit.
   - c. Monitor fluid intake.
   - d. Avoid the use of calcium supplements.
   - e. Monitor output.
6. A patient gained 10 lb in 2 days. It is determined that the weight gain is caused by fluid retention. The nurse correctly estimates that the weight gain may be equivalent to approximately how much fluid?
   - a. 2 L
   - b. 4 L
   - c. 10 L
   - d. 11 L
7. A patient has hypernatremia. Which components are appropriate to include in the nursing care plan? (Select all that apply.)
   - a. Seizure precautions
   - b. Need to keep appointments for laboratory tests and with health care provider
   - c. Signs and symptoms of hypernatremia (muscle cramps, weakness, fatigue)
   - d. Need for fluid restrictions
   - e. Need to read food labels
8. The nurse is reviewing the medication list of a patient with hypokalemia. Which products may be contributing to the cause of this imbalance? (Select all that apply.)
   - a. Cortisone
   - b. Licorice
   - c. Azithromycin
   - d. Estrogen
   - e. Digoxin

OBJECTIVES

- Explain the differences between enteral nutrition and parenteral nutrition.
- Describe the routes for enteral feedings.
- Discuss examples of enteral solutions, and explain the differences.
- Explain the advantages and differences of the methods used to deliver enteral nutrition.
- Describe the complications that may occur with use of enteral nutrition and parenteral nutrition.
- Discuss the nursing interventions for patients receiving enteral nutrition and parenteral nutrition.

Nutrients are needed for cell growth, cellular function, enzyme activity, carbohydrate-fat-protein synthesis, muscular contraction, wound healing, immune competence, and gastrointestinal (GI) integrity. Inadequate nutrient intake can result from surgery, trauma, malignancy, and other catabolic illnesses. Without adequate nutritional support, protein catabolism (breakdown), malnutrition, and diminished organ functioning will affect the GI, hepatic, renal, cardiac, and respiratory systems. The functioning of the immune system also is decreased.

Patients who are well nourished can usually tolerate a lack of nutrients for 14 days without major health problems. However, patients who are critically ill may only tolerate a lack of nutrient support for a short period (a few days to a week) before signs of impaired organ function, infection, or morbidity result. If nutritional support is started within hours of an injury, as in the cases of severe trauma or burns, recovery is more rapid. When injury is a result of minor surgery, no severe bodily harm results from lack of nutritional support for days. For both the critically ill and for patients with major injuries, early nutritional support improves intestinal and hepatic blood flow and function, enhances wound healing, decreases the occurrence of infection, and improves the general outcome of the health situation. "Early fed" injured patients have a positive nitrogen balance and less chance for bacterial infections; thus, they also have a decrease in institutional length of stay.

Dextrose 5% in water (D_5W), normal saline, and lactated Ringer's solution are not forms of nutritional support (supporting healthy tissue growth and wellness), although these solutions do provide fluids and some electrolytes. A patient requires 2000 calories per day; critically ill patients may require 3000 to 5000 calories per day. For individuals with extensive burns, the caloric need could be even greater. Patients who receive nothing by mouth (NPO) for an extended period become malnourished. Delayed nutritional support by as little as 5 days for a patient experiencing trauma or neurologic damage (e.g., cervical fracture) could hamper wound healing and increase the risk for developing an infection.

There are two routes for administering **nutritional support**: enteral and parenteral. **Enteral nutrition,** which involves the GI tract, can be given orally or by feeding tubes (tube feeding). If the patient can swallow, nutrient preparations can be taken by mouth; if the patient is unable to swallow, a tube is inserted into the stomach or small intestine. **Parenteral nutrition** involves administering high-caloric nutrients through large veins, for example, the subclavian vein. This method is called **total parenteral nutrition (TPN), hyperalimentation (HA), or** *intravenous hyperalimentation* (IVH). Parenteral nutrition is more costly (approximately three times more expensive) than enteral nutrition, and the benefits are not significant. In fact with TPN there is a higher infection rate than with enteral nutrition. The use of TPN does not promote effective GI integrity, hepatic function, or body weight gain, as enteral nutrition does. Enteral feedings require a functioning GI tract. TPN becomes necessary when the GI tract is incapacitated due to uncontrolled vomiting, malabsorption, or intestinal obstruction. TPN may also be necessary in patients with a high risk for aspiration or to supplement inadequate oral intake. TPN is also used for GI rest from exacerbations of Crohn's disease and ulcerative colitis; elemental nutrition absorbed by the duodenum and jejunum may be used for exacerbation of Crohn's disease involving the terminal ilium or ascending colon. TPN is also needed in conjunction with enteral feedings for patients with multiple trauma, including burn patients, when metabolic demand exceeds the number of calories that can be delivered by the GI system.

Solutions for enteral nutrition and parenteral nutrition include amino acids, carbohydrates, electrolytes, fats, trace elements, and vitamins.

ENTERAL NUTRITION

Enteral nutrition requires adequate small bowel function with digestion, absorption, and GI motility. To determine whether there is a lack of GI motility, the nurse assesses for abdominal distention and a decrease or absence of bowel sounds and notes if the patient has a bowel movement.

In critically ill patients, frequently there is a decrease or absence in gastric emptying time; then TPN may be necessary. The preferred method for nutritional support is enteral feedings for patients with intact gastric emptying and with a decreased risk of aspiration.

Routes for Enteral Feedings

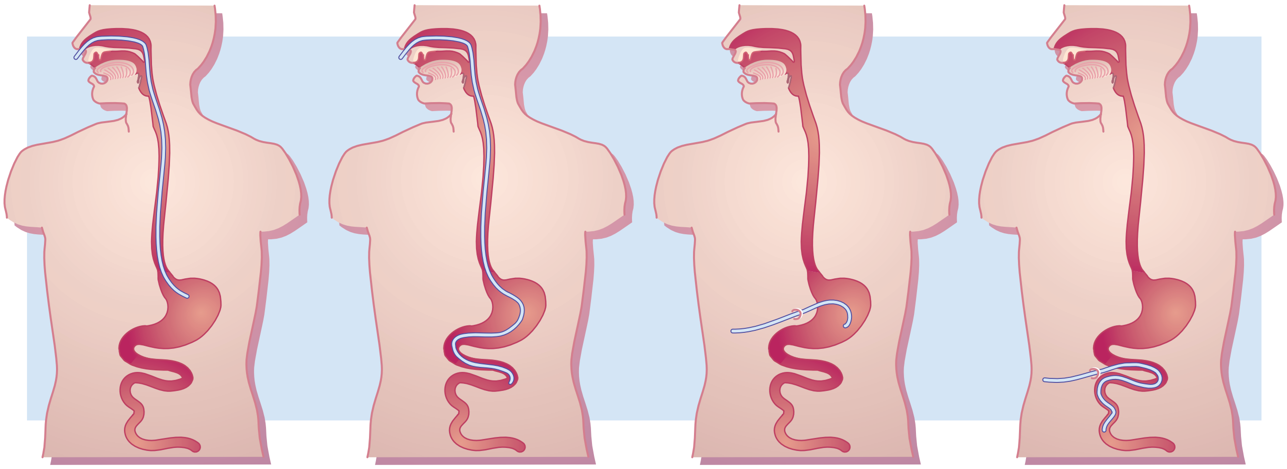
The routes for enteral feedings include: oral, gastric by **nasogastric tube** or **gastrostomy tube,** and small intestinal by nasoduodenal/nasojejunal or **jejunostomy tube**. Use of a nasogastric tube through oral (mouth) or nasal cavities is the most common route for short-term enteral feedings. The gastrostomy, nasoduodenal/nasojejunal, and jejunostomy tubes are used for long-term enteral feedings. Figure 17-1 displays the four types of GI tubes used for enteral feedings. If aspiration is a concern, the small intestinal route is suggested.

Enteral Solutions

Several types of liquid formulas are available for enteral feedings. These solutions differ according to their various nutrients, caloric values, and osmolality. The three groups of solutions for enteral nutrition are blenderized; polymeric (milk-based and lactose-free); and elemental or monomeric. Examples of commercial preparations are listed according to their groups in Table 17-1. Components of the enteral solutions include (1) carbohydrates in the form of dextrose, sucrose, lactose, starch, or dextrin (the first three are simple sugars that can be absorbed quickly); (2) protein in the form of intact proteins, hydrolyzed proteins, or free amino acids; and (3) fat in the form of corn oil, soybean oil, or safflower oil (some have a higher oil content than others). With all enteral nutrition, sufficient water to maintain hydration is essential.

Blended formulas for enteral solutions are liquid in consistency, so they are able to pass through the tube. These are individually prepared based on the patient's nutritional need. Frequently, baby food is used with liquid added. If food particles are too large, the tube can become clogged.

The two groups of polymeric solutions are milk based and lactose free. Most milk-based polymeric preparations come in powdered form to be mixed with milk or water. Many of these solutions do not provide complete nutritional requirements unless given in large amounts. Frequently they are used as a supplement to meet nutritional needs. Lactose-free polymeric solutions are commercially prepared in liquid form for replacement feedings. Many of these solutions are isotonic (300 to 340 mOsm/kg water), and the breakdown of nutrients includes 50% carbohydrates, 15% protein, 15% fat, and 20% other nutrients. Examples of polymeric solutions include



Nasogastric

Nasoduodenal/nasojejunal

Gastrostomy

Jejunostomy

FIGURE 17–1 Types of gastrointestinal tubes used for enteral feedings. A nasogastric tube is passed from the nose into the stomach. A weighted nasoduodenal/nasojejunal tube is passed through the nose into the duodenum/jejunum. A gastrostomy tube is introduced through a temporary or permanent opening on the abdominal wall (stoma) into the stomach. A jejunostomy tube is passed through a stoma directly into the jejunum.

TABLE 17-1 COMMERCIAL PREPARATIONS FOR ENTERAL FEEDING

TYPE OF FORMULA	COMMERCIAL PREPARATION	DESCRIPTION
Blenderized	Compleat	Blended natural foods Formulas come ready to use
Polymeric Milk-based Lactose-free	Meritene Sustacal Boost Ensure Entrition Fibersource Isocal Osmolite Resource Ultracal	Supplements prescribed for patients who have normal or near-normal gastrointestinal function Usually taste good Most commonly prescribed formula May be used as tube feeding, meal replacement, or oral supplement Contains protein, carbohydrates, and fat Adequate quantities meet reference daily intakes for vitamins and minerals
Elemental (monomeric)	Criticare HN Peptamen Liquid Vital HN Vivonex TEN	Partially digested nutrients for feeding Contains nitrogen (free amino acids), carbohydrates (glucose polymers), and minimal fat (long-chain triglycerides) Used for various gastrointestinal diseases

Ensure, Isocal, and Osmolite. These solutions provide 1 calorie per milliliter of feeding.

Characteristics of the formula may be targeted to treat a specific group of disorders. For those with diabetes mellitus, Glucerna and Diabetic Resource (low-carbohydrate, high-fat, lactose-free products) are most helpful. NutriHep (low-fat, lactose-free product) is recommended to treat hepatic disorders. For individuals with pulmonary disorders, Pulmocare or Respalor (low-carbohydrate, high-fat products) are commonly prescribed. Nepro and Novasource Renal (low-fat amino acids, water-soluble vitamins) are used to treat those with renal disorders.

For partial GI tract dysfunction, the elemental or monomeric solutions are useful (e.g., Peptinex DT). They are available in powdered and liquid forms. The nutrients from these solutions are rapidly absorbed in the small intestine. They are more expensive than the other enteral solutions.

Methods for Delivery

Enteral feedings may be given by **bolus,** intermittent drip or infusion, continuous drip, or cyclic infusion. The bolus method was the first method used to deliver enteral feedings. With the bolus method, 250 to 400 mL of solution is rapidly administered through a syringe or funnel into the tube four to six times a day. This method takes about 10 minutes each feeding, and may not be tolerated well by the patient because a massive volume of solution is given in a short period. This method can cause nausea, vomiting, aspiration, abdominal cramping, and diarrhea, but a healthy patient can normally tolerate the rapidly infused solution. This method is usually reserved for ambulatory patients.

Intermittent enteral feedings are administered every 3 to 6 hours over 30 to 60 minutes by gravity drip or pump infusion. At each feeding, 300 to 400 mL of solution is usually given. A feeding bag is commonly used. **Intermittent infusion** is considered an inexpensive method for administering enteral nutrition.

Continuous feedings are prescribed for the critically ill or for those who receive feedings into the small intestine. The enteral feedings are given by an infusion pump such as the Kangaroo set to control the flow at a slow rate over 24 hours. Approximately 50 to 125 mL of solution is infused per hour.

The **cyclic method** is another type of continuous feeding that is infused over 8 to 16 hours daily (day or night). Administration during daytime hours is suggested for patients who are restless or for those who have a greater risk for aspiration. The nighttime schedule allows more freedom during the day for patients who are ambulatory.

Complications

Dehydration can occur if an insufficient amount of water is given with or between feedings. Some enteral solutions are hyperosmolar and can draw water out of the cells to maintain serum iso-osmolality.

Aspiration pneumonitis is the major complication of enteral nutrition and may occur if the patient is fed while lying down or is unconscious. The head of the bed should be elevated at least 30 to 45 degrees. The nurse should check for gastric residual by gently aspirating the stomach contents before administering the next enteral feeding and every 4 hours minimum between feedings.

One of the major problems of enteral feeding is diarrhea. This could be caused by rapid administration of feeding, high caloric solutions, malnutrition, GI bacteria *(Clostridium difficile),* and drugs. Antibacterials and drugs that contain magnesium (e.g., antacids [Maalox], sorbitol [used as filler for certain drugs]) are associated with the occurrence of diarrhea. Many oral liquid drugs are hyperosmolar and tend to pull water into the GI tract and cause diarrhea.

Diarrhea can usually be managed or corrected by decreasing the rate of infusion of the enteral solution, diluting the solution, changing the solution, discontinuing the drug, increasing the patient's daily water intake, or administering enteral solution containing fiber.

Monitoring is essential when the patient is receiving enteral nutrition. Recommended parameters to monitor include: blood chemistry; BUN, creatinine, and electrolytes; glucose; triglycerides; serum proteins; I&O; and weight. Frequency of monitoring is patient dependent and more frequent at initiation of enteral nutrition.

Enteral Safety

The American Society for Parenteral and Enteral Nutrition (ASPEN) initiated the Be A.L.E.R.T. campaign to promote safe tube feeding:

Aseptic technique: For preparation and delivery of enteral formula, practice good hand-washing technique, wear gloves when handling feeding tube, and avoid touching can tops, container openings, spike, and spike port.

Label enteral equipment: Label with patient name (and location), formula name and rate, date and time of initiation, and nurse's initials. Equipment is changed every 24 hours; ensure that new equipment is labeled.

Elevate head of bed at least 30 degrees: Elevate when clinically possible, as it may mitigate the risk of reflux and aspiration of gastric content.

Right patient, right formula, right tube: Match the formula and rate to the patient's feeding order; verify enteral tubing set; connect formula container to feeding tube.

Trace all lines and tubing back to patient: avoid misconnections; trace all lines from origin to patient; only enteral-to-enteral connections.

Refer to the Agency for Healthcare Research and Quality National Guideline Clearinghouse website at *guideline.gov/content.aspx* for practice recommendations on initiation and advancement of enteral feedings; enteral feeding pumps; patient positioning; flushes; enteral misconnections; and special considerations for preterm infants.

Enteral Medications

Pancreatic enzymes such as pancreatin (Creon) and pancrelipase (Viokase) are products used by individuals with pancreatic enzyme deficiency resulting from conditions such as pancreatectomy, pancreatic obstruction, and cystic fibrosis. Both these preparations promote digestion and absorption of foods normally accomplished by natural amylase, lipase, and protease. Best given before meals, these artificial enzymes promote digestion and absorption of food.

Most drugs that can be administered orally can also be given via enteral tube. The drug must be in liquid form or dissolved into a liquid. Drugs that cannot be dissolved are time-release forms, enteric-coated forms, sublingual forms, and bulk-forming laxatives.

Liquid medication must be properly diluted when administered through the feeding tube. The drug dose is usually given as a bolus and then followed with water. Most liquid medications are hyperosmolar (>1000 mOsm/kg water) compared with the osmolality of the secretions of the GI tract (130 to 350 mOsm/kg water). Although the hyperosmolality of liquid medication was once thought to be well tolerated by the GI tract, abdominal distention and cramping, vomiting, and diarrhea can result from the administration of undiluted hyperosmolar liquid medications and electrolyte solutions. Liquid medication should be diluted with water to reduce the osmolality to 500 mOsm/kg H_2O (mildly hypertonic) and thus decrease GI intolerance. Table 17-2 lists the osmolalities of various commercial drug suspensions and solutions.

It is essential to know the importance of temporarily stopping the infusion when certain types of medications are administered. Some medications require that the feeding be stopped for as long as 30 minutes to allow for adequate absorption. For example, absorption of phenytoin suspension (Dilantin) is significantly reduced in the presence of protein, so it is important to stop the feeding for 1 hour before and after administering this drug. The phenytoin order may be changed to an injectable form to avoid the tube

TABLE 17-2 OSMOLALITY OF SELECTED DRUG SUSPENSIONS AND SOLUTIONS

DRUG	AVERAGE mOsm/kg
acetaminophen elixir, 65 mg/mL	5400
amoxicillin suspension, 50 mg/mL	2250
cephalexin (Keflex) suspension, 50 mg/mL	1950
cimetidine (Tagamet) solution, 60 mg/mL	5500
digoxin elixir, 50 mcg/mL	1350
docusate sodium (Colace) syrup, 3.3 mg/mL	3900
furosemide (Lasix) solution, 10 mg/mL	2050
lithium citrate syrup, 1.6 mEq/mL	6850
milk of magnesia suspension	1250
potassium chloride liquid, 10%	3550
prochlorperazine syrup, 1 mg/mL	3250
theophylline solution, 5.33 mg/mL	800

feeding being off for 2 hours at a time, especially if the patient is diabetic and requires insulin while on enteral feeding. The therapeutic effect of a drug may be affected as well. Sucralfate (Carafate), a treatment for gastric ulcers, may lose its effectiveness if the feeding is not held for 30 minutes after administering the medication.

Nursing Process

Patient-Centered Collaborative Care

Enteral Nutrition

Assessment

- Confirm that the feeding tube is securely in place.
- Assess patient's tolerance to enteral feeding, including possible GI disturbance (nausea, cramping, diarrhea).
- Determine urine output, and record for future comparison.
- Obtain patient's weight to be used for future comparisons.
- Listen for bowel sounds. Report diminished or absent bowel sounds immediately to health care provider. Also palpate abdomen for distention and percuss.
- Assess baseline laboratory values. Compare with future laboratory results.

Nursing Diagnoses

- Deficient fluid volume related to inadequate fluid intake or excess fluid loss
- Diarrhea related to ingredients in enteral feedings
- Risk for aspiration related to enteral feedings via nasogastric tube
- Imbalanced nutrition, less than body requirements, related to inability to absorb nutrients or tolerate oral intake

Planning

- Patient will not aspirate during enteral feedings (especially with nasogastric tube route).
- Patient will receive adequate nutritional support through enteral feedings.
- Complication of diarrhea related to enteral feedings will be managed.

Nursing Interventions

- Check tube placement by aspirating gastric secretion or injecting air into tube to listen by stethoscope for air movement in the stomach. (However, injecting air to check for placement may be misleading, because the tube may be in the base of the lung and air flow there produces similar sounds as when the tube is placed in the stomach.) For placement of the tube for small intestine route, confirmation by x-ray may be needed.
- Determine gastric residual before enteral feeding. A residual of more than 50% of previous feeding indicates delayed gastric emptying. Notify health care provider. Usual residual is 0 to 100 mL.
- Check continuous route for gastric residual every 2 to 4 hours. If residual is more than 50 mL, stop infusion for 30 minutes to 1 hour and then recheck.
- Raise head of bed to a 30- to 45-degree angle at all times during infusion of tube feedings. If elevating head of bed is contraindicated, then position patient on right side.
- Deliver enteral feeding according to method ordered: bolus, gastric, or small intestine.
- Flush feeding tube accordingly: intermittent feeding, 30 mL before and after; continuous feeding, every 4 hours; medications, 30 mL before and after. If tube obstruction occurs, flush with warm water or cola.
- Monitor adverse effects of enteral feedings such as diarrhea. To manage or correct diarrhea, decrease enteral feeding flow rate, and as diarrhea lessens gradually increase feeding rate. Enteral solution may be diluted and then gradually increased to full strength. However, diluted solution can decrease nutrient intake. Determine whether drugs could be causing diarrhea.
- Dilute drug solution's osmolality to 500 mOsm when giving liquid medication through the tube. Consult with health care provider.
- Monitor vital signs. Report abnormal findings.
- Give additional water during the day to prevent dehydration. Consult with health care provider.
- Weigh patient to determine weight gain or loss. Compare with baseline weight. Patient should be weighed at the same time each day with same scale and same amount of clothing.
- Change feeding bag daily. Do not add new solution to old solution in feeding bag. Nutritional solution should be room temperature.

Patient Teaching

- Instruct patient to report any problems related to enteral feedings such as diarrhea, sore throat, and abdominal cramping.

Cultural Considerations

- Respect cultural beliefs concerning refusal to receive enteral nutrition or TPN. Explain the need for adequate nutrition, and find ways that nutritional needs can be met.
- Communicate, verbally or in writing, how enteral nutrition is used by various cultural groups such as those in developing countries.
- Use an interpreter as appropriate.

Evaluation

- Determine that patient is receiving prescribed nutrients daily and is free of complications associated with enteral feedings.

PARENTERAL NUTRITION

Total Parenteral Nutrition

TPN is the primary method for providing complete nutrients by the parenteral or IV route. TPN is an infusion of hyperosmolar glucose, amino acids, vitamins, electrolytes, minerals, and trace elements; it can meet a patient's total nutritional needs. TPN is indicated for patients with severe burns who are in negative nitrogen balance; patients with GI disorders whose GI tract needs a complete rest; patients with absorption problems such as pancreatitis, Crohn's disease, and ulcerative colitis; and patients with debilitating diseases such as metastatic cancer or acquired immunodeficiency syndrome (AIDS).

The nutritional content of TPN generally includes water 30 to 40 mL/kg/d; energy 30 to 60 kcal/kg/d; amino acids 1 to 2 g/kg/d; essential fatty acids; vitamins; and minerals. Solutions differ for pediatric patients, who have varied fluid needs and require more energy and amino acids per kg/d.

The average percentage of dextrose in TPN is 25%. This high glucose concentration is mixed with commercially prepared protein and lipid sources. Fat emulsion supplement therapy provides an increased number of calories and is a carrier of fat-soluble vitamins. Vitamins and electrolytes are added before administration. Electrolytes are frequently added immediately before the infusion based on assessments of the patient's serum electrolyte levels. High glucose concentrations are irritating to peripheral veins, so TPN is administered through central venous lines, such as the subclavian or internal jugular, or through PICC lines.

Enteral feedings should be considered before TPN. Enteral feeding poses less risk of sepsis, maintains GI integrity, and is less costly. When enteral nutrition cannot be used because of severe GI disorders, TPN should be prescribed. TPN enhances wound healing and provides the necessary nutrients to prevent cellular catabolism.

The nurse must be familiar with the specific equipment used in caring for the patient on TPN. A variety of "setups" are available for administration. Some tubings have antireflux valves, and others have clamps. Each has implications for the administration of medications. Parenteral preparations must be administered by infusion pump to ensure accurate flow rate.

Management of patients requiring parenteral and enteral nutrition is best accomplished by an interdisciplinary team approach, including a nurse, physician, dietician, and pharmacist. Policies and procedures for TPN therapy may vary by region and institution and must be researched and followed accordingly.

Complications

Complications associated with TPN can result from catheter insertion and TPN infusion. Table 17-3 lists the complications associated with TPN.

To prevent air embolism, all central lines should have slide clamps on them to be closed completely when the solution bag and tubing are changed. Strict asepsis is necessary when changing IV tubing and dressings at the insertion site. Gloves, masks, and antibacterial ointment are usually necessary. TPN solution is an excellent medium for organism growth. Hypertonic dextrose in a protein hydrolysate solution promotes yeast and bacterial growth. It has been reported that these organisms do not grow as rapidly in the preferred crystalline amino acid solution as they do in a protein hydrolysate solution. Refrigerate prepared solutions, and administer within 24 hours. Most TPN solutions are prepared by the pharmacist with the use of a laminar airflow hood.

Hyperglycemia occurs primarily as a result of the hypertonic dextrose solution of 20% or greater when TPN is initiated. This may be transient until the pancreas adjusts to the hyperglycemic load. Hyperglycemia also occurs when the infusion rate for TPN is too rapid. In some cases, insulin is added to the TPN solution, which tends to be more effective than administering the insulin subcutaneously. Usually 1 L of solution is ordered for the first 24 hours when initiating TPN therapy. This allows the pancreas to accommodate to the increased glucose concentration of the solution. Additional daily increases of 500 to 1000 mL are ordered until the desired daily volume of 2.5 to 3 L is reached.

Sudden interruption of TPN therapy can cause hypoglycemia. After the glucose level is decreased, the insulin level remains, causing a hypoglycemic state. It is suggested that an isotonic dextrose solution be administered for 12 to 24 hours after TPN therapy is discontinued. A gradual decrease in the hourly infusion rate of TPN may also be used to discontinue TPN therapy. This process decreases the possibility of a hypoglycemic reaction.

TPN solutions and tubing should be changed every 24 hours. Dressing changes are required every 48 to 72 hours, varying by agency policy. In some institutions, the dressing is changed every 24 hours for the first 7 to 10 days.

TABLE 17-3 COMPLICATIONS OF TOTAL PARENTERAL NUTRITION

COMPLICATION	CAUSES	SYMPTOMS
Catheter Insertion		
Pneumothorax	Accidental puncture of the pleural cavity	Sharp chest pain, decreased breath sounds
Hemothorax	Catheter damages the large vein	Same as pneumothorax
Hydrothorax	Catheter perforates the vein, releasing solution into the chest	Same as pneumothorax
Total Parenteral Nutrition Infusion		
Air embolism	Intravenous (IV) tubing disconnected. Catheter not clamped. Injection port fell off. Improper changing of IV tubing (no **Valsalva maneuver**).	Coughing, shortness of breath, chest pain, cyanosis
Infection	Poor aseptic technique when catheter inserted. Contamination when changing tubing, mixing solution, or changing dressing.	Temperature >100° F (37.7° C). Tachycardia; chills; sweating; redness; swelling; drainage at insertion site; neck, arm, or shoulder pain; lethargy
Hyperglycemia	Fluid infused too rapidly. Insufficient insulin coverage. Infection.	Nausea, headache, weakness, thirst, elevated blood glucose
Hypoglycemia	Fluids stopped abruptly. Too much insulin infused.	Pallor; cold, clammy skin; increased pulse rate; "shaky feeling"; headache; blurred vision
Fluid overload hypervolemia	Increased IV rate. Fluids shift from cellular to vascular spaces because of hypertonic solutions.	Cough, dyspnea, neck vein engorgement, chest rales, metabolic complications

Nursing Process

Patient-Centered Collaborative Care

Total Parenteral Nutrition

Assessment

- Obtain baseline vital signs for future comparison.
- Confirm baseline weight.
- Determine laboratory results (electrolytes, glucose, protein [pre-albumin], and white blood cell levels frequently change during TPN therapy). Early laboratory results are useful for future comparison.
- Check urine output. Report abnormal findings.
- Read the label on TPN solution. Compare solution with order.
- Assess TPN insertion site for erythema, leaking, and edema.

Nursing Diagnoses

- Risk for imbalanced fluid volume related to excess fluid infusion or renal dysfunction or osmotic diuresis resulting from hyperosmolar TPN solution
- Risk for imbalanced nutrition related to altered type of nutritional support
- Risk for infection related to TPN solution that has a high glucose concentration
- Ineffective breathing pattern related to complication from insertion of subclavian line
- Deficient knowledge related to TPN therapy

Planning

- Patient's nutrient needs will be met via TPN.
- Infection will be avoided.

Nursing Interventions

- Check vital signs, and report changes.
- Determine body weight, and compare with baseline weight.
- Monitor laboratory results and report abnormal findings, especially electrolytes, protein, and glucose. Compare laboratory changes with baseline findings.
- Measure intake and output. Fluid volume deficit or excess could occur. Because the TPN solution is hyperosmolar, fluid shift occurs, which can cause osmotic diuresis.
- Monitor temperature changes for possible infection or febrile state. Use aseptic technique when changing dressings and solution bottles or bags.
- Check blood glucose level periodically. When TPN therapy is started, there may be a transient elevated glucose level until pancreatic beta cells adjust to secretion of insulin. If this occurs, the flow rate for TPN should be started slowly and gradually increased as blood glucose level decreases. Regular insulin may be added to TPN fluids to correct elevated glucose levels.
- Refrigerate TPN solution that is not in use. High glucose concentration is an excellent medium for bacterial growth.

- Monitor flow rate of TPN. Start with 60 to 80 mL/h, and increase slowly to the ordered level to avoid hyperglycemia.
- Hang dextrose 10% if TPN finishes before the next time it is to be administered.
- Have patient perform Valsalva maneuver (taking deep breath, holding it, and bearing down) in the absence of clamp to close tubing completely during solution bag/tubing change to prevent air embolus. Valsalva maneuver may cause dysrhythmias, so monitor cardiac status.
- Check for signs and symptoms of overhydration: coughing, dyspnea, neck vein engorgement, or chest rales. Report findings.
- Follow the agency policy for changing dressing and tubing. Usually tubing is changed daily, and dressing is changed every 24 hours for first 10 days and every 48 hours thereafter.
- Do not draw blood, give medications, or check central venous pressure via TPN line. Results could be invalid.

Patient Teaching

- Provide emotional support to patient and family before and during TPN therapy.
- Be available to discuss patient concerns, or refer patient to appropriate health care provider.
- Instruct patient to notify health care provider immediately if experiencing discomfort or reactions.
- Keep patient informed of progress and effectiveness of TPN.

Cultural Considerations

- Respect patient's cultural beliefs about refusing TPN.
- Explain reasons for adequate nutrition, and find ways to meet nutritional needs.
- Use an interpreter as appropriate.

Evaluation

- Evaluate patient's positive and negative response to TPN therapy.
- Determine periodically whether patient's serum electrolytes, protein, and glucose levels are within desired ranges.
- Evaluate nutritional status by weight changes, energy level, feeling of well-being, symptom control, or healing.
- Evaluate patient and family's understanding of purpose and possible complications of TPN therapy.

TRANSITIONAL FEEDING: PARENTERAL TO ENTERAL

The first stage of transitioning from parenteral to enteral feeding is determining a patient's GI tolerance, accomplished by giving a small amount of enteral feeding at a slow rate of about 25 to 40 mL/h. As the enteral rate is increased every 8 to 24 hours by increments of 25 to 40 mL, the parenteral preparation is reduced by the appropriate amount. Parenteral nutrition is typically discontinued when about 75% to 80% of a patient's nutritional needs are being met through enteral feeding.

KEY WEBSITES

American Society for Parenteral and Enteral Nutrition: *www.nutritioncare.org*

Infusion Nurses Society: *www.ins1.org*

CRITICAL THINKING CASE STUDY

MM had abdominal surgery and received D$_5$W and D$_5$ 0.45% NaCl for 4 days. A nasogastric tube was inserted for enteral nutrition. It was determined that the function of MM's GI tract was intact.

1. Why would MM receive enteral nutrition? Is enteral nutrition needed for short-term or long-term therapy?
2. Differentiate between Ensure solution and other forms of enteral solutions.
3. MM is at risk for complications related to enteral nutrition. Discuss potential complications, and give specific nursing interventions for each.
4. Differentiate methods of delivery of enteral nutrition. Describe nursing interventions related to each method.
5. Give the rationale for changing MM's enteral nutrition from bolus method to intermittent method.

NCLEX STUDY QUESTIONS

1. The nurse is determining a patient's gastric residual before administering an enteral feeding; the last feeding was 240 mL. The patient will be discharged on enteral feedings. It is important to include in the health teaching plan that a residual of more than which amount would indicate delayed gastric emptying (based on last feeding)?
   - **a.** 100 mL
   - **b.** 125 mL
   - **c.** 150 mL
   - **d.** 175 mL
2. The nurse is assisting a patient with self-administration of an enteral feeding. It is important to include in the health teaching plan that the feeding should be administered at which temperature?
   - **a.** Slightly warmed
   - **b.** Chilled
   - **c.** Ice cold
   - **d.** Room temperature
3. The nurse is reviewing the plan of care for a patient receiving enteral therapy. What is the most common complication of enteral therapy?
   - **a.** Aspiration
   - **b.** Constipation
   - **c.** Diarrhea
   - **d.** Muscle weakness
4. Which is appropriate nursing care for a patient receiving total parenteral nutrition (TPN) in an acute care setting? (Select all that apply.)
   - **a.** Monitor blood glucose levels periodically.
   - **b.** Measure intake and output each shift.
   - **c.** Administer blood products through the TPN line.
   - **d.** Monitor TPN insertion site for erythema, leaking, or edema.
   - **d.** Monitor the patient's weight monthly for significant changes.
5. A patient has been on TPN for 1 month, and there is an order to discontinue TPN tomorrow. The nurse contacts the health care provider because sudden interruption of TPN therapy may cause which condition?
   - **a.** Dehydration
   - **b.** Tremors
   - **c.** Urinary retention
   - **d.** Hypoglycemia
6. A patient is receiving TPN at home. The visiting nurse assists the family with the care plan, which includes changing the TPN solution and tubing. What is the recommended initial frequency for changing the tubing?
   - **a.** Every 24 hours
   - **b.** Every 36 hours
   - **c.** Every 48 hours
   - **d.** Every 72 hours
7. The visiting nurse has a caseload of adult and pediatric patients receiving TPN at home and is checking all orders for TPN solutions. Which order (all have appropriate amounts of essential fatty acids, vitamins, and minerals) requires the nurse to contact the health care provider?
   - **a.** Adults: water 32 mL/kg/d; energy 32 kcal/kg/d; amino acids 1.2 g/kg/d
   - **b.** Adults: energy 34 kcal/kg/d; amino acids 2 g/kg/d
   - **c.** Children: water 32 mL/kg/d; energy 120 kcal/kg/d; amino acids 2.5 g/kg/d
   - **d.** Children: water 38 mL/kg/d; energy 58 kcal/kg/d; amino acids 2 g/kg/d
8. The nurse is reviewing the care plan with a patient using enteral nutrition. Which interventions by the nurse are appropriate for this strategy? (Select all that apply.)
   - **a.** Check continuous route for gastric residual every 2-4 hours.
   - **b.** Raise head of bed to a 30- to 45-degree angle before administering.
   - **c.** Change the feeding bag every 3 days.
   - **d.** Report diminished or absent bowel sounds to health care provider.
   - **e.** Explain that any diarrhea the patient experiences is related to the nutrition.
9. The nurse is to administer enteral medications to a patient who cannot swallow and is receiving continuous enteral feedings. Which is correct concerning administration of the enteral medications?
   - **a.** Ordered medications are added to the enteral feeding solution.
   - **b.** Liquid medications are diluted, given as a bolus, and followed with water.
   - **c.** Extra amounts of water are used to dissolve time-release medications.
   - **d.** Undiluted hyperosmolar medications may be given to a patient on a fluid restriction.

UNIT V

Autonomic Nervous System Agents

The central nervous system (CNS) is the body's primary nervous system, consisting of the brain and spinal cord. The peripheral nervous system (PNS), located outside the brain and spinal cord, is made up of two divisions: the autonomic and the somatic. After interpretation by the CNS, the PNS receives stimuli and initiates responses to these stimuli.

The autonomic nervous system (ANS), also called the visceral system, acts on smooth muscles and glands. Its functions include control and regulation of the heart, respiratory system, gastrointestinal tract, bladder, eyes, and glands. The ANS is an involuntary nervous system over which we have little or no control. We breathe, our hearts beat, and peristalsis continues without our realizing it. However, unlike the ANS, the somatic nervous system is a voluntary system that innervates skeletal muscles over which there is control.

The two sets of neurons in the autonomic component of the PNS are the (1) afferent (sensory) neurons and the (2) efferent (motor) neurons. The afferent neurons send impulses to the CNS, where they are interpreted. The efferent neurons receive the impulses (information) from the brain and transmit these impulses through the spinal cord to the effector organ cells. The efferent pathways in the ANS are divided into two branches: the sympathetic and the parasympathetic nerves. Collectively, these two branches are called the sympathetic nervous system and the parasympathetic nervous system (Figure V-1).

The sympathetic and parasympathetic nervous systems act on the same organs but produce opposite responses to provide homeostasis (balance) (Figure V-2). Drugs act on the sympathetic and parasympathetic nervous systems by either stimulating or depressing responses.

SYMPATHETIC NERVOUS SYSTEM

The sympathetic nervous system is also called the adrenergic system because at one time it was believed that *adrenaline* was the neurotransmitter that innervated smooth muscle. The neurotransmitter, however, is norepinephrine.

The adrenergic receptor organ cells are of four types: alpha$_1$, alpha$_2$, beta$_1$, and beta$_2$ (Figure V-3). Norepinephrine is released from the terminal nerve ending and stimulates the cell receptors to produce a response.

PARASYMPATHETIC NERVOUS SYSTEM

The parasympathetic nervous system is called the cholinergic system because the neurotransmitter at the end of the neuron that innervates the muscle is acetylcholine.

The cholinergic receptors at organ cells are either nicotinic or muscarinic, meaning that they are stimulated by the alkaloids nicotine and muscarine, respectively (see Figure V-3). Acetylcholine stimulates the receptor cells to produce a response, but the enzyme acetylcholinesterase may inactivate acetylcholine before it reaches the receptor cell.

Drugs that mimic the neurotransmitters norepinephrine and acetylcholine produce responses opposite to each other in the same organ. (Table V-1 lists the organ responses from drugs that act on these systems.) For example, an adrenergic drug (sympathomimetic) increases the heart rate, whereas a cholinergic drug (parasympathomimetic) decreases the heart rate (see Figure V-2). However, a drug that mimics the sympathetic nervous system and a drug that blocks the parasympathetic nervous system can cause similar responses in the organ. For instance, the sympathomimetic and the parasympatholytic (block impulses from PNS) drugs both increase heart rate; the adrenergic blockers and the cholinergic drugs both decrease heart rate.

Many name classifications are given to drugs that mimic or block both the sympathetic nervous system and the parasympathetic nervous system (Table V-2). The nurse must become familiar with these names. Drug names and specific actions are discussed in Chapter 18, Adrenergic Agonists and Adrenergic Blockers, and Chapter 19, Cholinergic Agonists and Anticholinergics.

OBJECTIVES

- Explain major responses to stimulation of adrenergic receptors.
- Differentiate between selective and nonselective adrenergic agonists.
- Contrast the uses of alpha blockers and beta blockers.
- Compare general side effects of adrenergic agonists and adrenergic blockers.
- Describe nursing interventions, including patient teaching, associated with adrenergic agonists and adrenergic blockers.
- Apply the nursing process for the patient taking beta-adrenergic blockers.
- Compare the indications of adrenergic agonists and adrenergic blockers.

This chapter discusses two groups of drugs that affect the sympathetic nervous system: adrenergic agonists (**sympathomimetics**) and adrenergic blockers (**sympatholytics**), along with their dosages and uses.

ADRENERGIC AGONISTS

Drugs that stimulate the sympathetic nervous system are called *adrenergics, adrenergic agonists,* or *sympathomimetics,* because they mimic the sympathetic neurotransmitters norepinephrine and epinephrine. They act on one or more **adrenergic receptor** sites located in the effector cells of muscles, such as the heart, bronchiole walls, gastrointestinal (GI) tract, urinary bladder, and ciliary muscle of the eye. There are many adrenergic receptors. The four main receptors are alpha$_1$, alpha$_2$, beta$_1$, and beta$_2$, which mediate the major responses described in Table 18-1 and illustrated in Figure 18-1.

TABLE 18-1 EFFECTS OF ADRENERGIC AGONISTS AT RECEPTORS

RECEPTOR	PHYSIOLOGIC RESPONSES
$Alpha_1$	Increases force of heart contraction; vasoconstriction increases blood pressure; mydriasis (dilation of pupils) occurs; decreases secretion in salivary glands; increases urinary bladder relaxation and urinary sphincter contraction
$Alpha_2$	Inhibits release of norepinephrine; dilates blood vessels; produces hypotension; decreases gastrointestinal motility and tone
$Beta_1$	Increases heart rate and force of contraction; increases renin secretion, which increases blood pressure
$Beta_2$	Dilates bronchioles; promotes gastrointestinal and uterine relaxation; promotes increase in blood sugar through glycogenolysis in liver; increases blood flow in skeletal muscles

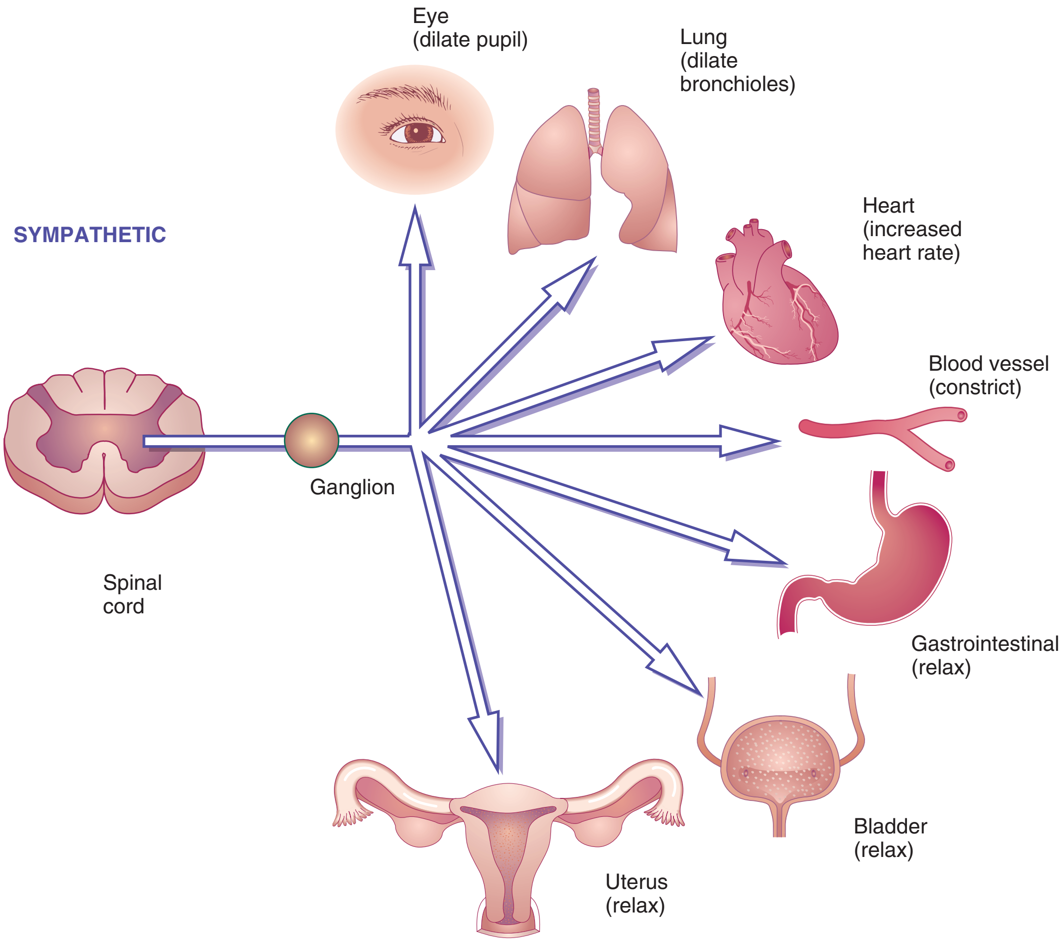

FIGURE 18–1 Sympathetic responses. Stimulation of the sympathetic nervous system or use of sympathomimetic (adrenergic agonist) drugs can cause the pupils and bronchioles to dilate; heart rate to increase; blood vessels to constrict; and muscles of the gastrointestinal tract, bladder, and uterus to relax, thereby decreasing contractions.

The alpha-adrenergic receptors are located in blood vessels, eye, bladder, and prostate. When the $alpha_1$ receptors in vascular tissues (vessels) of muscles are stimulated, the arterioles and venules constrict, increasing peripheral resistance and blood return to the heart. Circulation is improved, and blood pressure is increased. When there is too much stimulation, blood flow is decreased to the vital organs.

The $alpha_2$ receptors are located in the postganglionic sympathetic nerve endings. When stimulated, they inhibit the release of norepinephrine, leading to a decrease in vasoconstriction. This results in vasodilation and a decrease in blood pressure.

The $beta_1$ receptors are located in the kidney but primarily in the heart. Stimulation of the $beta_1$ receptor increases myocardial contractility and heart rate.

The $beta_2$ receptors are found mostly in the smooth muscles of the lung and gastrointestinal tract, the liver, and the uterine muscle. Stimulation of the $beta_2$ receptor causes (1) relaxation of the smooth muscles of the lungs, resulting in bronchodilation; (2) a decrease in gastrointestinal tone and motility; (3) activation of glycogenolysis in the liver and increased blood glucose; and (4) relaxation of the uterine muscle, resulting in a decrease in uterine contraction (Figure 18-2; see also Table 18-1).

FIGURE 18–2 Effects of activation of alpha$_1$, alpha$_2$, beta$_1$, and beta$_2$ receptors.

Another adrenergic receptor is dopaminergic and is located in the renal, mesenteric, coronary, and cerebral arteries. When this receptor is stimulated, the vessels dilate and blood flow increases. Only dopamine can activate this receptor.

Inactivation of Neurotransmitters

After the neurotransmitter (e.g., norepinephrine) has performed its function, the action must be stopped to prevent prolonging the effect. Transmitters are inactivated by (1) reuptake of the transmitter back into the neuron (nerve cell terminal), (2) enzymatic transformation or degradation, and (3) diffusion away from the receptor. The mechanism of norepinephrine reuptake plays a more important role in inactivation than the enzymatic action. Following the reuptake of the transmitter in the neuron, the transmitter may be degraded or reused. The two enzymes that inactivate norepinephrine are (1) monoamine oxidase (MAO), which is inside the neuron; and (2) catechol-O-methyltransferase (COMT), which is outside of the neuron.

Drugs can prolong the action of the neurotransmitter (e.g., norepinephrine) by either (1) inhibiting the norepinephrine reuptake, which prolongs the action of the transmitter or (2) inhibiting the degradation of norepinephrine by enzyme action.

FIGURE 18–3 **A,** Direct-acting sympathomimetics; **B,** indirect-acting sympathomimetics; and **C,** mixed-acting sympathomimetics.

Classification of Sympathomimetics

The sympathomimetic drugs that stimulate adrenergic receptors are classified into three categories according to their effects on organ cells. Categories include (1) direct-acting sympathomimetics, which directly stimulate the adrenergic receptor (e.g., epinephrine or norepinephrine); (2) indirect-acting sympathomimetics, which stimulate the release of norepinephrine from the terminal nerve endings (e.g., amphetamine); and (3) mixed-acting sympathomimetics (both direct and indirect acting), which stimulate the adrenergic receptor sites and stimulate the release of norepinephrine from the terminal nerve endings (e.g., ephedrine) (Figure 18-3).

Pseudoephedrine is an example of a mixed-acting sympathomimetic. This drug acts indirectly by stimulating the release of norepinephrine from the nerve terminals and acts directly on the alpha$_1$ and beta$_1$ receptors. Pseudoephedrine, like epinephrine, increases heart rate. It is not as potent a vasoconstrictor as epinephrine, and there is less risk of hemorrhagic stroke and hypertensive crisis. Pseudoephedrine is helpful to relieve nasal and sinus congestion without rebound congestion.

Catecholamines are the chemical structures of a substance (either endogenous or synthetic) that can produce a sympathomimetic response. Examples of endogenous catecholamines are epinephrine, norepinephrine, and dopamine. The synthetic catecholamines are isoproterenol and dobutamine. Noncatecholamines (e.g., phenylephrine, metaproterenol, albuterol) stimulate the adrenergic receptors. Most noncatecholamines have a longer duration of action than the endogenous or synthetic catecholamines.

Many of the adrenergic agonists stimulate more than one of the adrenergic receptor sites. An example is epinephrine (Adrenalin), which acts on alpha$_1$-, alpha $_2$-, beta$_1$-, and beta$_2$-adrenergic receptor sites. The responses from these receptor sites include increase in blood pressure, pupil dilation, increase in heart rate (tachycardia), and bronchodilation. In anaphylactic shock, epinephrine is useful because it increases blood pressure, heart rate, and airflow through the lungs. Because epinephrine affects different adrenergic receptors, it is **nonselective.** Additional side effects result when more responses occur than are desired. Pseudoephedrine, ephedrine, and phenylpropanolamine are commonly used for illegal production of amphetamine and methamphetamine. These drugs are considered OTC drugs but may be obtained in limited amounts per month. Stores are required to keep these drugs behind the counter or in a locked cabinet and keep a log of purchases for at least 2 years. Prototype Drug Chart 18-1 lists the pharmacologic behavior of epinephrine.

Epinephrine

Pharmacokinetics Epinephrine can be administered subcutaneously, intravenously, topically, or by inhalation, intracardiac, and instillation methods. It is not given orally, because it is rapidly metabolized in the GI tract and liver resulting in unstable serum levels. The percentage by which the drug is protein-bound and its half-life are unknown. Epinephrine is metabolized by the liver and excreted in the urine.

Pharmacodynamics Epinephrine is frequently used in emergencies to treat anaphylaxis, which is a life-threatening allergic response. Epinephrine is a potent inotropic (strengthens myocardial contraction) drug that increases cardiac output, promotes vasoconstriction and systolic blood pressure elevation, increases heart rate, and produces bronchodilation. High doses can result in cardiac dysrhythmias necessitating electrocardiogram (ECG) monitoring. Epinephrine can also cause renal vasoconstriction, thereby decreasing renal perfusion and urinary output.

The onset of action and peak concentration times are rapid. The use of decongestants with epinephrine has an additive effect. When epinephrine is administered with digoxin, cardiac dysrhythmias may occur. Beta blockers can antagonize the action of epinephrine. Tricyclic antidepressants and monoamine oxidase inhibitors (MAOIs) allow epinephrine's effects to be intensified and prolonged. Epinephrine is also discussed in Chapter 59 as one of the drugs used during emergencies.

Albuterol

Albuterol sulfate (Proventil), a beta$_2$-adrenergic agonist, is **selective** for beta$_2$-adrenergic receptors, so the response is relaxation of bronchial smooth muscle and bronchodilation. A patient with asthma may tolerate albuterol better than isoproterenol (which activates beta$_1$ and beta$_2$ receptors) because

PROTOTYPE DRUG CHART 18-1

Epinephrine

Drug Class
Sympathomimetic: adrenergic agonist
Trade Name: Adrenalin
Pregnancy Category: C

Dosage
Anaphylaxis:
A: subQ: 0.3-0.5 mL of 1 : 1000 PRN
IV: 0.1-0.25 mg of 1 : 10,000 infused slowly over 5-10 min
A: subQ/IM: 0.3 mg EpiPen autoinjector

Contraindications
Cardiac tachydysrhythmias, cerebral arteriosclerosis, pregnancy, narrow-angle glaucoma, cardiogenic shock
Caution: Hypertension, prostatic hypertrophy, hyperthyroidism, pregnancy, diabetes mellitus (hyperglycemia could result)

Drug-Lab-Food Interactions
Drug: Increased effects with tricyclic antidepressants and MAOIs. Methyldopa and beta blockers antagonize epinephrine effects. Digoxin may cause dysrhythmias with epinephrine.
Lab: Increase blood glucose, serum lactic acid

Pharmacokinetics
Absorption: subQ/IM/IV: Rapidly; inactivated in GI tract
Distribution: PB: UK
Metabolism: t½: UK
Excretion: In urine and breast milk

Pharmacodynamics
subQ: Onset: 5-15 min
Peak: 20 min
Duration: 1-4 hours
IV: Onset: Immediate
Peak: 2-5 min
Duration: 5-10 min
Inhal: Onset: 1-5 min
Peak: 3-5 min
Duration: 1-3 hours

Therapeutic Effects/Uses
To treat allergic reaction, anaphylaxis, asthma, bronchospasm, severe hypotension, cardiac arrest
Mode of Action: Acts on alpha and beta receptors; promotion of CNS and cardiac stimulation and bronchodilation; strengthens cardiac contraction, increases cardiac rate and cardiac output; reduces mucosal congestion by inhibiting histamine release; reverses anaphylactic reactions

Side Effects
Anorexia, nausea, vomiting, nervousness, tremors, agitation, sweating, headache, pallor, insomnia, weakness, dizziness

Adverse Reactions
Palpitations, tachycardia, hypertension, dyspnea. Necrosis and gangrene of IV site upon infiltration
Life-threatening: Ventricular fibrillation, pulmonary edema

A, Adult; *CNS,* central nervous system; *IM,* intramuscular; *Inhal,* inhalation; *IV,* intravenous; *min,* minute; *PB,* protein-binding; *PRN,* as needed; *subQ,* subcutaneous; *t½,* half-life; *UK,* unknown.

albuterol's action is more selective (activates only the beta$_2$ receptors). By using selective sympathomimetics, fewer undesired adverse effects will occur. However, high dosages of albuterol may affect beta$_1$ receptors, causing an increase in heart rate. Prototype Drug Chart 18-2 lists the drug data related to albuterol.

Pharmacokinetics Albuterol sulfate (Proventil, Ventolin) is well absorbed from the GI tract and is extensively metabolized by the liver. The half-life of the drug differs slightly according to the route of administration (oral route is 2.7 to 6 hours; inhalation route is 3.5 hours).

Pharmacodynamics The primary use of albuterol is to prevent and treat bronchospasm. With inhalation, the onset of action of albuterol is faster than with oral administration, though the duration of action is the same for both oral and inhalation preparations.

Tremors, restlessness, and nervousness may occur when albuterol is taken. Tremors and nervousness are the most common side effects of oral or inhalation albuterol. If albuterol is taken with an MAOI, hypertensive crisis can result. Beta blockers may inhibit the action of albuterol. Albuterol and the beta$_2$ drugs are also discussed in Chapter 41 and 44, respectively.

CENTRAL-ACTING ALPHA AGONISTS

Clonidine and Methyldopa

Clonidine (Catapres) is a selective alpha$_2$-adrenergic agonist (sympathomimetic) used primarily to treat hypertension. Alpha$_2$ drugs act by decreasing the release of norepinephrine from sympathetic nerves and decreasing peripheral adrenergic receptor activation. Alpha$_2$ drugs also produce vasodilation by stimulating alpha$_2$ receptors in the central nervous system (CNS), leading to a decrease in blood pressure (see Chapter 44).

Methyldopa (Aldomet) is an alpha-adrenergic agonist (sympathomimetic) that acts within the CNS. This drug is taken up into the brainstem neurons and converted to methylnorepinephrine, which is an alpha$_2$-adrenergic agonist that leads to alpha$_2$ activation. The decrease of sympathetic outflow from the CNS causes vasodilation and a reduction in blood pressure (see Chapter 44).

PROTOTYPE DRUG CHART 18-2

Albuterol

Drug Class

Beta$_2$-adrenergic agonist
Trade Names: Proventil, Ventolin
Pregnancy Category: C

Dosage

A: PO: 2-4 mg, t.i.d./q.i.d.; *max:* 32 mg/d in 4 divided doses
SR: 4-8 mg, q12h
Inhal: 1-2 puffs q4-6h PRN
Nebulizer: 0.5 mL of 0.5% sol in 3 mL of 0.9% NaCl in 5-15 min
2 to 6 y: PO: 0.1-0.2 mg/kg/t.i.d.; *max:* 4 mg/dose
6 to 12 y: PO: 2 mg, t.i.d./q.i.d.
6 to 12 y: Inhal: 1-2 puffs q4-6h PRN

Contraindications

Cardiac dysrhythmias, coronary artery disease
Caution: Severe cardiac disease, hypertension, hyperthyroidism, diabetes mellitus, renal dysfunction, older adults, pregnancy

Drug-Lab-Food Interactions

Drug: Increase effect with other sympathomimetics; may increase effect with MAOIs and tricyclic antidepressants
Antagonize effect with beta-adrenergic blockers (beta blockers)
Lab: May increase glucose level slightly; may decrease serum potassium level

Pharmacokinetics

Absorption: Well absorbed from the GI tract after oral administration; well absorbed from respiratory tract after inhalation
Distribution: PB: UK
Metabolism: $t_{1/2}$: PO: 2.7-6 h; Inhal: 3.5 h
Excretion: 75% excreted in the urine

Pharmacodynamics

PO: Onset: 30 min
Peak: 2-3 h
Duration: 4-6 h
Inhal: Onset: 5-15 min
Peak: 0.5-2 h
Duration: 2-6 h

Therapeutic Effects/Uses

To treat bronchospasm, asthma, bronchitis, and other COPD
Mode of Action: Stimulates beta$_2$-adrenergic receptors in the lungs, which relaxes the bronchial smooth muscle, thus causing bronchodilation

Side Effects

Tremor, dizziness, nervousness, restlessness, sweating, blurred vision, flushing, headache, hoarseness, pharyngitis, nasal congestion, insomnia, weakness, nausea, diarrhea

Adverse Reactions

Palpitations, tachycardia, hypertension, hallucinations, seizures, hyperglycemia
Life-threatening: Cardiac dysrhythmias, Stevens-Johnson syndrome

A, Adult; *C,* child; *COPD,* chronic obstructive pulmonary disease; *d,* day; *GI,* gastrointestinal; *h,* hour; *Inhal,* inhalation; *MAOI,* monoamine oxidase inhibitor; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *q.i.d.,* four times a day; *SR,* sustained release; *sol,* solution; $t_{1/2}$, half-life; *t.i.d.,* three times a day; *UK,* unknown; *y,* year.

Side Effects and Adverse Reactions

Additional undesired side effects frequently result when the drug dosage is increased or the drug is nonselective. Side effects commonly associated with adrenergic agonists include hypertension, tachycardia, palpitations, restlessness, tremors, dysrhythmias, dizziness, urinary retention, nausea, vomiting, dyspnea, and pulmonary edema.

Names of adrenergic drugs, the receptors they activate, dosage information, and common uses are listed in Table 18-2.

Nursing Process

Patient-Centered Collaborative Care

Adrenergic Agonist

Assessment

- Record baseline vital signs for future comparison.
- Assess the patient's drug history.
- Determine patient's health history. Most adrenergic agonists are contraindicated if the patient has cardiac dysrhythmias, narrow-angle glaucoma, or cardiogenic shock.
- Determine baseline glucose level.

Nursing Diagnoses

- Disturbed sleep pattern related to adverse drug effect of insomnia
- Deficient knowledge related to drug administration

Planning

- Patient's vital signs will be within acceptable ranges.
- Patient will experience therapeutic effects by improved blood pressure, breathing pattern, and cardiac output.

Nursing Interventions

- Administer epinephrine 1 mg (10 mL of a 1:10,000 concentration per AHA guidelines) IV for cardiac

TABLE 18-2 ADRENERGIC AGONISTS (ALPHA$_1$, BETA$_1$, AND BETA$_2$)

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
epinephrine (Adrenalin Chloride) Alpha$_1$, beta$_1$, and beta$_2$	See Prototype Drug Chart 18-1.	
ephedrine HCl, ephedrine sulfate (Pretz-D) l Alpha$_1$, beta$_1$, and beta$_2$	A: PO: 25-50 mg t.i.d./q.i.d. subQ/IM/IV: 12.5-50 mg; *max:* 150 mg/24 h C: >2 y: PO: 2-3 mg/kg/d in 4-6 divided doses; *max:* 3 mg/kg/24 h	To treat hypotensive states, bronchospasm, nasal congestion. Also may be used to treat mild cases of asthma. Drug resistance may occur with prolonged use of ephedrine. If this occurs, stop drug for 3-5 d, and then resume. Pregnancy category: C; PB: UK; t½: 3-6 h
norepinephrine bitartrate (Levophed) Alpha$_1$ and beta$_1$	A: IV: 4 mg in 500-1000 mL of D_5W or D_5NS infused initially 8-12 mcg/min, then titrated to maintain blood pressure; monitor blood pressure	To treat shock by potent vasoconstriction. Increases blood pressure and cardiac output. Monitor blood pressure and rhythm every 2-5 min during infusion. Pregnancy category: C; PB: UK; t½: UK
dopamine HCl (Intropin) Alpha$_1$ and beta$_1$	A: IV/INF: 2-5 mcg/kg/min initially; gradually increase 5-10 mcg/kg/min; *max:* 50 mcg/kg/min C: IV: 1-5 mcg/kg/min; increase 2.5-5 mcg/kg/min; *max:* 20 mcg/kg/min	To correct hypotension. Does not decrease renal function in doses <5 mcg/kg/min. Pregnancy category: C; PB: UK; t½: 2 min
midodrine (ProAmatine) Alpha$_1$	A: PO: 10 mg t.i.d.; *max:* 30 mg/d	To treat symptomatic orthostatic hypotension. Blood pressure may increase by 15-30 mm Hg in 1 h with 1 10-mg dose. Pregnancy category: C; PB: UK; t½: 3-4 h
phenylephrine HCl (12-hour spray, Afrin 4 hrNeo-Synephrine) Alpha	Nasal decongestant: A: 2-3 sprays q4h PRN Hypotension: A: IM/subQ: 1-5 mg initially, then 1-10 mg q10-15min PRN	To treat nasal congestion; acts as a decongestant. Used for patients with common cold, sinusitis, allergic rhinitis. Have patient blow nose before drug is administered. Nasal decongestant therapy should not exceed 3 days. Pregnancy category: C; PB: UK; t½: 2.5 h
pseudoephedrine HCl (Sudafed) Alpha and beta$_1$	Nasal decongestant: A: PO: 60 mg q4-6h; PO/SR: 120 mg q12h; *max:* 240 mg/d C: >2 y: PO: 15 mg q4-6h; *max:* 60 mg/d C: 6-12 y: PO: 30 mg q4-6h; *max:* 120 mg/d	To treat nasal congestion. OTC drug but controlled by placement behind counter or locked up. Check label for contraindications. Avoid taking with a history of hypertension, cardiac disease, or diabetes mellitus. Pregnancy category: C; PB: UK; t½: 9-16 h
albuterol (Proventil, Ventolin) Beta$_2$	See Prototype Drug Chart 18-2.	
metaproterenol sulfate (Alupent) Beta$_2$	A and C: >9 y: PO: 20 mg q6-8h Older adults: 10 mg initially; may increase to 20 mg q6-8h C: 6 to 9 y: PO: 10 mg t.i.d./q.i.d. A and C: >12 y: Inhal: 2-3 puffs q3-4h; *max:* 12 puffs/d	To treat bronchospasm by bronchodilation. Pregnancy category: C; PB: UK; t½: UK
dobutamine HCl (Dobutrex) Beta$_1$	A and C: IV: 0.5-1 mcg/kg/min initially; increase dose gradually; *max:* 40 mcg/kg/min	To treat cardiac decompensation (which may result from cardiogenic shock or cardiac surgery) by enhancing myocardial contractility, stroke volume, and cardiac output. Pregnancy category: C; PB: UK; t½: 2 min
terbutaline sulfate Beta$_2$	Bronchodilator: A: PO: 2.5-5 mg t.i.d.; SC: 0.25 mg initially; no more than 0.5 mg in 4 h	Used primarily to correct bronchospasm. Pregnancy category: C; PB: 25%; t½: 3-4 h

A, Adult; *C,* child; *d,* day; *FDA,* U.S Food and Drug Administration; *gtt,* drops; *h,* hour; *IM,* intramuscular; *inf,* infusion; *inhal,* inhalation; *IPPB,* intermittent positive pressure breathing; *IV,* intravenous; *min,* minute; *NSS,* normal saline solution; *OTC,* over-the-counter; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *q.i.d.,* four times a day; *SL,* sublingual; *sol,* solution; *SR,* sustained release; *subQ,* subcutaneous; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *y,* year; *>,* greater than; *<,* less than.

resuscitation; may repeat q3-5 min. Follow each dose with 20-mL saline flush to ensure proper delivery. Normally, epinephrine is administered 1 mg IV over 1 minute or more; however, in cardiac arrest, it may be given more rapidly.

- Monitor IV site frequently when administering norepinephrine bitartrate (Levarterenol) or dopamine (Intropin) because extravasation of these drugs causes tissue necrosis. These drugs should be diluted sufficiently in IV fluids.

- Administer antidote, phentolamine mesylate (Regitine) 5 to 10 mg, diluted in 10 to 15 mL of saline infiltrated into the area for IV extravasation of norepinephrine (Levophed) and dopamine.
- Record patient's vital signs. Report signs of increasing blood pressure and increasing heart rate. If patient receives an alpha-adrenergic agonist intravenously for shock, check the blood pressure q3-5min or as indicated to avoid severe hypertension.
- Monitor ECG for dysrhythmias when given IV.
- Report side effects of adrenergic drugs: tachycardia, palpitations, tremors, dizziness, and increased blood pressure.
- Check patient's urinary output, and assess for bladder distention. Urinary retention can result from high drug dose or continuous use of adrenergic agonists.
- Offer food to patient when giving adrenergic agonists to avoid nausea and vomiting.
- Evaluate blood glucose levels in patients with diabetes mellitus because they may be increased.

Patient Teaching

General

- Advise patient to read labels on all over-the-counter (OTC) drugs for cold symptoms and diet pills. Many of these have properties of sympathetic (adrenergic agonists, sympathomimetics) drugs and should not be taken if patient is hypertensive or has diabetes mellitus, cardiac dysrhythmias, or coronary artery disease.
- Explain to patient that continuous use of nasal sprays or drops that contain adrenergic agonists may result in rebound (inflamed and congested tissue) nasal congestion.

Self-Administration

- Encourage patient to take medication as prescribed.
- Advise patient and family on proper administration of drug and allow return demonstration. Cold medications by spray or drops in the nostrils should be used with the head in an upright position. Use of nasal spray while lying down can cause systemic absorption. Coloration of nasal spray or drops might indicate deterioration.
- Notify health care provider if EpiPen is needed more than twice a week.
- Encourage patient to have EpiPen readily available at all times and to store additional medication in a cool, dark place (refrigeration is not recommended).
- Teach patient and family that EpiPen must be taken immediately upon the initial occurrence of difficulty breathing, wheezing, hoarseness, hives, itching, or swelling of lips and tongue.
- Teach patient to administer EpiPen properly. Inspect solution for particles or discoloration prior to administration. Do not use if particles are pink to brown in color. Take care to inject subcutaneously and not intradermally, and to apply sufficient pressure to activate EpiPen while holding device in place for 5 to 10 seconds. The EpiPen should be inserted into outer thigh. After administration, massage injection site for 10 seconds to promote absorption and reduce vasoconstriction and tissue irritation.

Side Effects

- Encourage patient to report side effects (e.g., rapid heart rate, palpitations, rash, itching, flushing, chest pain, irregular heartbeat, vomiting, numbness of fingers and toes) to a health care provider as dose may require adjustment.

Cultural Considerations

- Decrease language barriers for patients with language difficulties and for those who do not work in the health care field by decoding the jargon of the health care environment.

Evaluation

- Evaluate patient's response to the adrenergic agonist.
- Evaluate patient's vital signs, and report abnormal findings. Epinephrine stimulates alpha$_1$ (increases blood pressure), beta$_1$ (increases heart rate), and beta$_2$ (dilates bronchial tubes) receptors. Albuterol (Proventil) stimulates beta$_2$ receptors.
- Report possible drug-drug interactions. Beta blockers decrease the effect of epinephrine and albuterol. Over-the-counter cold and allergy drugs, caffeine, alcohol, herbs, and dietary supplements may lead to interactions.

ADRENERGIC BLOCKERS (ANTAGONISTS)

Drugs that block the effects of adrenergic neurotransmitters are called **adrenergic blockers,** adrenergic antagonists, or sympatholytics. They act as antagonists to adrenergic agonists by blocking the alpha and beta receptor sites. Most adrenergic blockers block either the alpha receptor or the beta receptor. They block the effects of the neurotransmitter either directly by occupying the receptors or indirectly by inhibiting the release of the neurotransmitters norepinephrine and epinephrine. Table 18-3 lists the effects of alpha blockers and beta blockers at receptors.

Alpha-Adrenergic Blockers

Drugs that block or inhibit a response at the alpha-adrenergic receptor site are called alpha-adrenergic blockers or **alpha blockers.** Alpha-blocking agents are divided into two groups: selective alpha blockers that block alpha$_1$, and nonselective alpha blockers that block alpha$_1$ and alpha$_2$. Because alpha-adrenergic blockers can cause orthostatic hypotension and reflex tachycardia, many of these drugs are not as frequently prescribed as beta blockers.

TABLE 18-3 **EFFECTS OF ADRENERGIC BLOCKERS AT RECEPTORS**

RECEPTOR	RESPONSES
Alpha$_1$	Vasodilation: decreases blood pressure; reflex tachycardia might result; miosis (constriction of pupil) occurs; suppresses ejaculation; reduces contraction of smooth muscle in bladder neck and prostate gland
Beta$_1$	Decreases heart rate; reduces force of contractions
Beta$_2$	Constricts bronchioles; contracts uterus; inhibits glycogenolysis, which can decrease blood sugar

Alpha blockers promote vasodilation, causing a decrease in blood pressure. If vasodilation is long-standing, orthostatic hypotension can result. Dizziness may also be a symptom of a drop in blood pressure. As blood pressure decreases, pulse rate usually increases to compensate for the low blood pressure and inadequate blood flow. Alpha blockers can be used to treat peripheral vascular disease (e.g., Raynaud's disease). Vasodilation occurs, permitting more blood flow to the extremities. These drugs are also helpful in decreasing symptoms of benign prostatic hypertrophy. Alpha blockers are also discussed in Chapter 44.

Beta-Adrenergic Blockers

Beta-adrenergic blockers, commonly called **beta blockers,** decrease heart rate, and a decrease in blood pressure usually follows. Some beta blockers are nonselective, blocking both beta$_1$ and beta$_2$ receptors. Not only does the heart rate decrease because of beta$_1$ blocking, but bronchoconstriction also occurs. Nonselective beta blockers (block both beta$_1$ and beta$_2$) should be used with extreme caution in any patient who has chronic obstructive pulmonary disease (COPD) or asthma.

Propranolol hydrochloride (Inderal) was the first beta blocker prescribed to treat angina, cardiac dysrhythmias, hypertension, and heart failure. This medication is given for migraine prophylaxis. Although it is still prescribed today, propranolol has many side effects, partly because of its nonselective response in blocking both beta$_1$ and beta$_2$ receptors.

A selective adrenergic blocker has a greater affinity for certain receptors. If the desired effect is to decrease pulse rate and blood pressure, then a selective beta$_1$ blocker such as atenolol (Tenormin) or metoprolol tartrate (Lopressor) may be ordered.

Intrinsic sympathomimetic activity (ISA) is the ability of certain beta blockers to bind with a beta receptor to prevent strong agonists from binding to that receptor producing complete activation. Nonselective beta blockers (block both beta$_1$ and beta$_2$) that have ISA include carteolol, carvedilol, penbutolol, and pindolol. The selective blocker (blocks beta$_1$ only) that has ISA is acebutolol. These agents may be recommended for patients experiencing bradycardia.

Atenolol (Tenormin), a selective beta$_1$ blocker, is one of the most frequently prescribed drugs in the United States. Atenolol decreases sympathetic outflow to the periphery and suppresses the renin-angiotensin-aldosterone system response, It is contraindicated in bradycardia, heart block, cardiogenic shock, pulmonary edema, acute bronchospasm, and pregnancy. Prototype Drug Chart 18-3 describes the pharmacologic behavior of atenolol.

Beta blockers are useful in treating mild to moderate hypertension, angina pectoris, and myocardial infarction. The use of beta blockers as antihypertensives, antidysrhythmics, and drugs for angina is discussed in Chapters 42 and 44. Table 18-4 lists the alpha and beta blockers and their dosages, uses, and considerations.

Pharmacokinetics Atenolol is 50% absorbed from the GI tract. It does not readily cross the blood-brain barrier. It has a half-life of 3 to 6 hours and is eliminated in urine and feces.

Pharmacodynamics By blocking beta$_1$ receptors, atenolol decreases the heart rate, peripheral vascular resistance, force of cardiac contractions, cardiac output, as well as systolic and diastolic blood pressure. It is available in tablets and for intravenous administration. The onset of action of the oral preparation is 1 hour; peak time is 2 to 4 hours, and duration of action is 24 hours. This drug is effective for dosing once a day, especially for patients who do not adhere to schedules with drug doses of several times a day.

Drug Interactions

Many drugs interact with atenolol. Nonsteroidal antiinflammatory drugs (NSAIDs) decrease the hypotensive effect of atenolol. Hypotension can be potentiated if atenolol is taken with another antihypertensive, though this may be the desired result. When atenolol is given concurrently with atropine and other anticholinergics, absorption is increased. The risk of hypoglycemia is increased when the patient is taking insulin and sulfonylureas.

Side Effects and Adverse Reactions

The side effects commonly associated with beta blockers are bradycardia, hypotension, headache, dizziness, cold extremities, hypoglycemia, and bronchospasm. General side effects of beta-adrenergic blockers include cardiac dysrhythmias, flushing, hypotension, weakness, impotence or decreased libido, depression, and pulmonary edema. Usually the side effects are dose related.

Adrenergic Neuron Blockers

Drugs that block the release of norepinephrine from the sympathetic terminal neurons are called **adrenergic neuron blockers,** which are classified as a subdivision of the adrenergic blockers. The clinical use of neuron blockers is to decrease blood pressure. (Herbal Alert 18-1) Reserpine, an example of an adrenergic neuron blocker, is an

HERBAL ALERT 18-1

Reserpine

St. John's wort may antagonize the hypotensive effects of reserpine.

PROTOTYPE DRUG CHART 18-3

Atenolol

Drug Class

Beta$_1$-adrenergic blocker
Trade Name: Tenormin
Pregnancy Category: D

Dosage

Hypertension, angina:
A: PO: Initially 25-50 mg/d; may increase to 100 mg/d
Older adults: PO: 25-50 mg/d
Myocardial infarction:
A: PO: Initially 50 mg/d

Contraindications

Sinus bradycardia, heart block >first-degree, cardiogenic shock, pulmonary edema, acute bronchospasm, uncompensated cardiac failure, pregnancy, lactation
Caution: Renal dysfunction, diabetes mellitus

Drug-Lab-Food Interactions

Drug: *Increased* absorption with atropine and other anticholinergics, *decreased* effects with NSAIDs, *increased* risk of hypoglycemia with insulin and sulfonylureas, *increased* hypotension with prazosin and terazosin, *increased* lidocaine and verapamil levels with toxicity

Pharmacokinetics

Absorption: 50% absorbed in GI tract
Distribution: PB: 6%-16%
Metabolism: t½: 6-7 h
Excretion: Urine and feces

Pharmacodynamics

PO: Onset: 1 h
Peak: 2-4 h
Duration: 24 h

Therapeutic Effects/Uses

To treat hypertension, angina pectoris, myocardial infarction, and heart failure
Mode of Action: Selectively blocks beta$_1$-adrenergic receptor sites, decreases sympathetic outflow to the periphery, suppresses renin-angiotensin-aldosterone system

Side Effects

Drowsiness, dizziness, fainting, depression, alopecia, weakness, nausea, vomiting, diarrhea, cool extremities, impotence, decreased libido

Adverse Reactions

Bradycardia, hypotension, heart failure, masking of hypoglycemia
Life-threatening: Bronchospasm, pulmonary edema, dysrhythmias, thrombocytopenia

A, Adult; *COPD,* chronic obstructive pulmonary disease; *GI,* gastrointestinal; *h,* hour; *IV,* intravenously; *min,* minute; *NSAID,* nonsteroidal antiinflammatory drug; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown.

TABLE 18-4 ADRENERGIC BLOCKERS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
phentolamine mesylate (Regitine) Alpha$_1$	Treat catecholamine extravasation: A: Intradermal: 5-10 mg in 10 mL NS infiltrated into affected area within 12 h of extravasation	Antidote for dopamine, dobutamine, phenylephrine, epinephrine, and norepinephrine infiltration to prevent dermal necrosis. Redness and tissue warmth are signs of effective treatment. Pregnancy category: C; PB: UK; t½: 20 min
doxazosin mesylate (Cardura) Alpha$_1$	A: PO: 1 mg/d initially *max:* 16 mg/d for hypertension; *max:* 8 mg/d for BPH	To treat mild to moderate hypertension and BPH. Check for orthostatic hypotension. Dizziness, headache, syncope may occur. Pregnancy category: C; PB: 98%; t½: 22 h
prazosin HCl (Minipress) Alpha$_1$	A: PO: 1 mg h.s. initially 2-3 times/d; *max:* 20 mg/d C: 5 mcg/kg q6h; *max:* 15 mg/d	To manage mild to moderate hypertension. May be used in combination with other antihypertensive drugs. Pregnancy category: C; PB: 97%; t½: 2-4 h
terazosin HCl (Hytrin) Alpha$_1$	A: PO: initially 1 mg h.s., maint: 1-5 mg/d in 2 divided doses; *max:* 20 mg/d	To treat hypertension. May be used in combination with a diuretic or with other antihypertensive drugs. Also used to treat BPH. May cause dizziness, headache, edema, orthostatic hypotension. Pregnancy category: C; PB: 90%-94%; t½: 12 h
carvedilol (Coreg) Alpha$_1$, beta$_1$, and beta$_2$	A: PO: 6.25 mg b.i.d.; *max:* 50 mg/d	To treat hypertension and heart failure. Can be used alone or with a thiazide diuretic. Pregnancy category: C; PB: 98%; t½: 7-10 h

TABLE 18-4 ADRENERGIC BLOCKERS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
labetalol (Normodyne, Trandate) Alpha$_1$, beta$_1$, and beta$_2$	A: PO: 100 mg b.i.d.; dose may be increased q2-3d; *max:* 2400 mg/d; IV: 20 mg; repeat 20-80 mg at 10-min interval; *max:* 300 mg/d	To treat mild to severe hypertension. Pregnancy category: C; PB: 50%; t½: 2.5-8 h
penbutolol (Levatol) Beta$_1$ and beta$_2$	A: PO: 20 mg/d; *max:* 80 mg/d	To treat mild to moderate hypertension in patients with angina, prior MI, or heart failure. Patients with asthma should avoid taking the drug. Pregnancy category: C; PB: 80%-98%; t½: 5 h
propranolol HCl (Inderal) Beta$_1$ and beta$_2$	A: PO: Initially: 40 mg b.i.d.; increase q3-7d up to 160-480 mg/d in 2-3 divided doses; *max:* 640 mg/d	To manage hypertension, angina pectoris, and dysrhythmias. To prevent myocardial infarction and migraines. Pregnancy category: C; PB: 93%; t½: 2-6 h
nadolol (Corgard) Beta$_1$ and beta$_2$	A: PO: 40-80 mg/d; *max:* 320 mg/d for hypertension and 240 mg/d for angina	To manage hypertension and angina pectoris. Contraindicated in bronchial asthma and severe COPD because it blocks beta$_2$ receptors. Pregnancy category: C; PB: 30%; t½: 10-24 h
pindolol (Visken) Beta$_1$ and beta$_2$	A: PO: 5 mg b.i.d; maint: 10-30 mg in divided doses; *max:* 60 mg/d in divided doses	To manage hypertension. Contraindicated in asthma, COPD, and second- and third-degree heart block. Pregnancy category: B; PB: 40%; t½: 3-4 h
sotalol (Betapace) Beta$_1$ and beta$_2$	A: PO: 80 mg b.i.d.; may increase gradually. Average: 240-320 mg/d	To treat life-threatening ventricular arrhythmias. Correct hypokalemia and hypomagnesemia before initiating therapy. Pregnancy category: B; PB: 0%; t½: 12 h
timolol maleate (Blocadren) Beta$_1$ and beta$_2$	A: PO: Initially 10 mg b.i.d.; maint: 20-40 mg/d in 2 divided doses; *max:* 60 mg/d	To manage mild to moderate hypertension and dysrhythmias, and to prevent reinfarction after MI. For ophthalmic use to treat IOP. Unlabeled use: prophylaxis for migraine headache and stable angina. Use with caution in patients with asthma or COPD. Pregnancy category: C; PB: <10%; t½: 3-4 h
Selective Beta-Adrenergic Blockers		
metoprolol tartrate (Lopressor) Beta$_1$	Hypertension: A: PO: 50-100 mg/d in 1-2 divided doses; may increase weekly; *max:* 450 mg/d in divided doses Myocardial infarction: A: IV: 5 mg q2min in 3 doses, then PO 50-100 mg b.i.d.	To manage hypertension, angina pectoris, and postmyocardial infarction. Bradycardia, dizziness, and gastrointestinal distress may occur. Pregnancy category: C; PB: 12%; t½: 3-4 h
atenolol (Tenormin)Beta$_1$	See Prototype Drug Chart 18-3.	
acebutolol HCl (Sectral) Beta$_1$	A: PO: Initially: 200-400 mg/d; maint: 200-800 mg/d in 1 to 2 divided doses; *max:* 1200 mg/d Older adults: *max:* 800 mg/d	To treat mild to moderate hypertension, angina pectoris, and dysrhythmias. Check apical pulse; do not give if <60 beats/min. Pregnancy category: B; PB: 26%; t½: 3-4 h
betaxolol (Betoptic) Beta$_1$	Hypertension: A: PO: 5-10 mg/d; *max:* 20 mg/d	To treat hypertension and chronic open angle glaucoma. Ophthalmic preparation is used to decrease IOP. Pregnancy category: C; PB: 50%; t½: 15 h
bisoprolol fumarate (Zebeta) Beta$_1$	A: PO: Initially: 2.5-5 mg/d; *max:* 20 mg/d	To treat hypertension. Unlabeled use: angina pectoris. Long-acting beta blocker. May decrease heart rate and blood pressure. Pregnancy category: C; PB: 30%-36%; t½: 10-12 h
esmolol HCl (Brevibloc) Beta$_1$	A: IV: Loading dose: 500 mcg/kg/min for 1 min; then 50 mcg/kg/min for 4 min; *max:* 500 mcg/kg/min/loading dose; 200 mcg/kg/min for IV maintenance infusion	To treat supraventricular tachydysrhythmias. Unlabeled use: hypertension. Contraindications: heart block, bradycardia, cardiogenic shock, uncompensated heart failure. Pregnancy category: C; PB: 55%; t½: 9 min

A, Adult; *b.i.d.,* two times a day; *BPH,* benign prostatic hypertrophy; *C,* child; *COPD,* chronic obstructive pulmonary disease; *d,* day; *h,* hour; *IM,* intramuscular; *IOP,* intraocular pressure; *IV,* intravenous; *PB,* protein-binding; *PO,* by mouth; *PRN,* as necessary; *t½,* half-life; *UK,* unknown; >, greater than; <, less than.

antihypertensive agent. Effects of this drug closely resemble those of alpha- and beta-adrenergic blockers. Reserpine also reduces the serotonin and catecholamine transmitters. Depletion of these neurotransmitters may lead to severe mental depression. Reserpine is discussed in more detail in Chapter 44.

Nursing Process
Patient-Centered Collaborative Care

Adrenergic Neuron Blockers

Assessment
- Obtain baseline vital signs and electrocardiogram for future comparison. Bradycardia and decrease in blood pressure are common cardiac effects of adrenergic neuron blockers.
- Determine the drugs that the patient currently takes. Report if any are diuretics, NSAIDs, digoxin, MAOIs, or CNS depressants.
- Obtain patient's health history. Depression, peptic ulcer, and heart failure may result from taking an adrenergic neuron blocker, and these drugs could potentiate preexisting conditions.

Nursing Diagnoses
- Decreased cardiac output related to hypotension and bradycardia
- Risk for falls related to dizziness
- Fatigue related to medication adverse effects
- Sexual dysfunction related to adverse effects of erectile and ejaculatory dysfunction
- Noncompliance related to undesired adverse effects of erectile dysfunction

Planning
- Patient will adhere to the drug regimen.
- Patient's vital signs will be within the desired range.

Nursing Interventions
- Monitor patient's vital signs. Report marked changes such as marked decrease in blood pressure and heart rate.
- Report any complaints of excessive dizziness, lightheadedness, early morning insomnia, mental depression, or chest pain.
- Assist patient with ambulation to avoid falls from orthostatic hypotension, which is more common with high doses.
- Note any complaint of stuffy nose, because vasodilation may result and nasal congestion can occur.

Patient Teaching
General
- Encourage patient to adhere to the drug regimen.
- Advise patient that therapeutic effects of reserpine may not occur for 2 to 3 weeks after initiation of therapy.

Self-Administration
- Teach patient and family how to take pulse and blood pressure.
- Encourage patient to take reserpine at the same time every day and not to discontinue without permission of health care provider.

Side Effects
- Encourage patient to avoid orthostatic (postural) hypotension by slowly rising from supine or sitting positions to standing.
- Inform patient and family of possible mood changes when taking reserpine due to catecholamine depletion. Mood changes can include depression, detachment, inability to concentrate, nightmares, and suicidal tendencies.
- Warn patient that reserpine may cause impotence or decreased libido, which is usually dose related.
- Advise patient not to drive or engage in operation of dangerous equipment until the drug response is known.

Cultural Considerations
- Obtain interpreter when necessary. Do not rely on family members, who may not fully disclose because of honor or shame.
- Discuss ethnicity of interpreter, as well as the language desired when translation is needed. Provide an interpreter with the same ethnic background and gender if possible, especially when sensitive topics are being addressed.

Evaluation
- Evaluate effectiveness of the adrenergic neuron blocker. Vital signs must be stable within the desired range.

CRITICAL THINKING CASE STUDY

An older adult patient has asthma. An adrenergic agonist is selected for treatment.

1. What are the drug advantages and disadvantages associated with the use of an adrenergic agonist, such as ephedrine, metaproterenol, or albuterol, for this patient? Explain your answer.
2. Is age a factor in drug selection? Explain your answer.

An older adult patient has hypertension and asthma. An adrenergic blocker is selected for treatment.

1. What are the drug advantages and disadvantages associated with the use of doxazosin, prazosin, propranolol, metoprolol, and atenolol for this patient? Explain your answer.
2. What needs to be included when teaching this patient about the use of an adrenergic blocker?

NCLEX STUDY QUESTIONS

1. The nurse will monitor the patient taking albuterol (Proventil) for which conditions? (Select all that apply.)
   a. Palpitations
   b. Hypertension
   c. Hypoglycemia
   d. Bronchospasm
   e. Uterine contractions
2. Nadolol (Corgard) is prescribed for a patient. The nurse realizes that this drug is a beta-adrenergic blocker and that this drug classification is contraindicated for patients with which condition?
   a. Hypothyroidism
   b. Angina pectoris
   c. Bronchial asthma
   d. Liver dysfunction
3. The nurse realizes that beta$_1$ receptor stimulation is differentiated from beta$_2$ stimulation in that stimulation of beta$_1$ receptors leads to which condition?
   a. Increased bronchodilation
   b. Decreased uterine contractility
   c. Increased myocardial contractility
   d. Decreased blood flow to skeletal muscles
4. A patient is given epinephrine (Adrenalin), an adrenergic agonist (sympathomimetic). The nurse should monitor the patient for which condition?
   a. Decreased pulse
   b. Pupil constriction
   c. Bronchial constriction
   d. Increased blood pressure
5. A patient who is taking epinephrine is also taking several other medications. The nurse should realize that there is a possible drug interaction with which drugs? (Select all that apply.)
   a. albuterol (Proventil)
   b. metoprolol (Lopressor)
   c. propranolol (Inderal)
   d. digoxin (Lanoxin)
   e. methyldopa (Aldomet)
6. A patient is prescribed metoprolol (Lopressor) to treat hypertension. It is important for the nurse to monitor the patient for which condition? (Select all that apply.)
   a. Bradycardia
   b. Hypotension
   c. Ankle edema
   d. Decreased respirations
   e. Increased respirations
7. The nurse is administering atenolol (Tenormin) to a patient. Which concurrent drugs does the nurse expect to most likely cause an interaction? (Select all that apply.)
   a. ginseng supplement
   b. An NSAID, such as aspirin
   c. atropine, an anticholinergic
   d. haloperidol (Haldol)
   e. methyldopa (Aldomet)

Answers: 1, a, b; 2, c; 3, c; 4, d; 5, b, c, d; 6, a, b; 7, b, c.

OBJECTIVES

- Compare the responses of cholinergic agonists and anticholinergic drugs.
- Differentiate between direct-acting and indirect-acting cholinergic agonists.
- Contrast the major side effects of cholinergic agonists and anticholinergics.
- Differentiate the uses of cholinergic agonists and anticholinergics.
- Apply the nursing process, including patient teaching associated with cholinergic agonists and anticholinergics.
- Apply the nursing process for the patient taking neostigmine, a reversible cholinesterase inhibitor.

The two groups of drugs that affect the parasympathetic nervous system are the (1) cholinergic agonists (parasympathomimetics) and the (2) *anticholinergics* (parasympatholytics). The Unit V opener offers a discussion and comparison of the parasympathetic nervous system (parasympathomimetics and parasympatholytics) and the sympathetic nervous system.

CHOLINERGIC AGONISTS

Drugs that stimulate the parasympathetic nervous system are called **cholinergic agonists,** or **parasympathomimetics,** because they mimic the parasympathetic neurotransmitter acetylcholine. Cholinergic agonists are also called *cholinomimetics or cholinergic stimulants.* **Acetylcholine (ACh)** is the

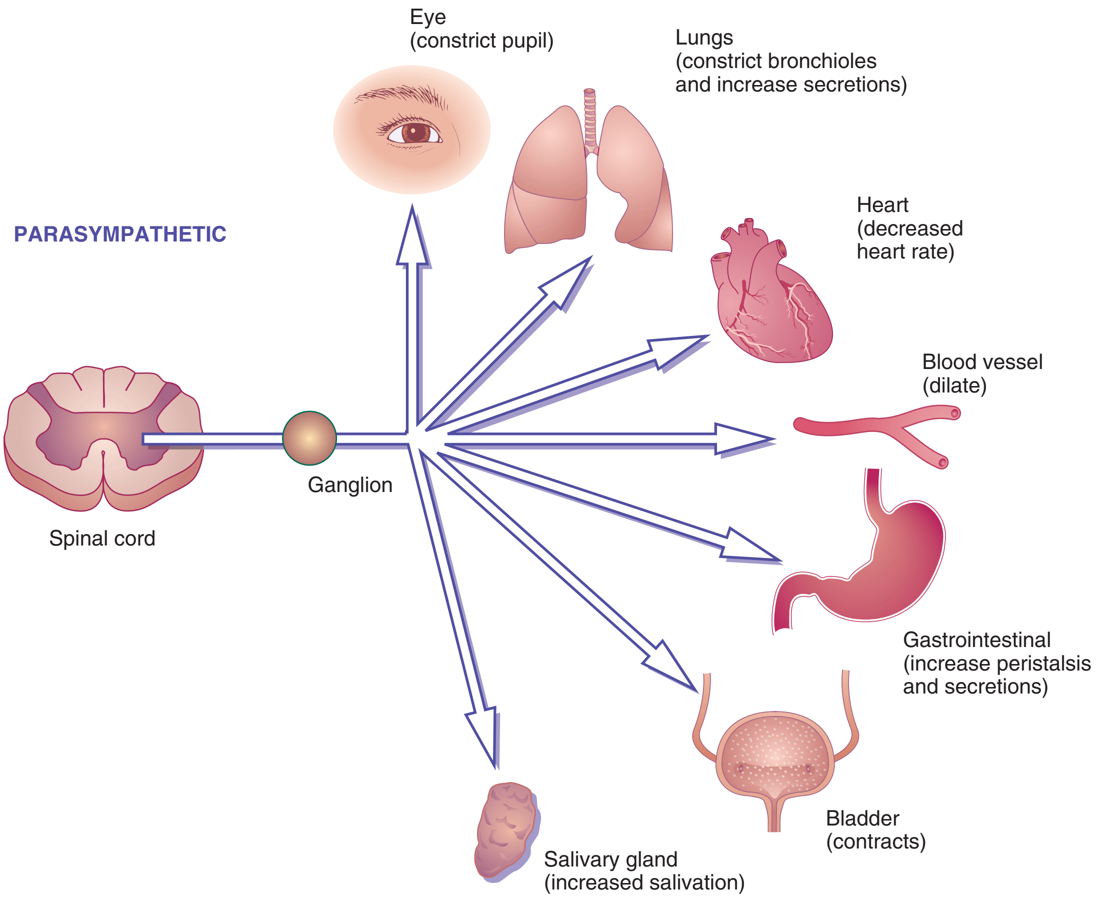

FIGURE 19–1 Parasympathetic responses. Stimulation of the parasympathetic nervous system or use of parasympathomimetic drugs will cause the pupils to constrict, bronchioles to constrict and bronchial secretions to increase, heart rate to decrease, blood vessels to dilate, peristalsis and gastric secretions to increase, the bladder muscle to contract, and salivary glands to increase salivation.

neurotransmitter located at the ganglions and the parasympathetic terminal nerve endings. It innervates cholinergic receptors in organs, tissues, and glands. The two types of cholinergic receptors are (1) **muscarinic receptors,** which stimulate smooth muscle and slow the heart rate; and (2) **nicotinic receptors** (neuromuscular), which affect the skeletal muscles. Many cholinergic agonists are nonselective because they can affect both the muscarinic and nicotinic receptors. However, there are selective cholinergic agonists for the muscarinic receptors that do *not* affect the nicotinic receptors. Figure 19-1 illustrates the effects of parasympathetic or cholinergic stimulation.

There are **direct-acting cholinergic agonists** and indirect-acting cholinergic agonists. *Direct-acting cholinergic agonists* act on receptors to activate a tissue response (Figure 19-2, *A*). *Indirect-acting cholinergic agonists* inhibit the action of the enzyme **cholinesterase (ChE)** (acetylcholinesterase) by forming a chemical complex, thus permitting acetylcholine to persist and attach to the receptor (Figure 19-2, *B*). Drugs that inhibit cholinesterase are called *cholinesterase inhibitors, acetylcholinesterase (AChE) inhibitors,* or **anticholinesterases.** Cholinesterase may destroy acetylcholine before it reaches the receptor or after it has attached to the site. By inhibiting or destroying the enzyme cholinesterase, more acetylcholine is available to stimulate the receptor and remain in contact with it longer.

Cholinesterase inhibitors (anticholinesterases) can be separated into reversible inhibitors and irreversible inhibitors. The reversible inhibitors bind the enzyme cholinesterase for several minutes to hours, and the irreversible inhibitors bind the enzyme permanently. The resulting effects vary with how long the cholinesterase is bound.

The major responses of cholinergic agonists are to stimulate bladder and gastrointestinal (GI) tone, constrict the pupils of the eyes **(miosis),** and increase neuromuscular transmission. Other effects of cholinergic agonists include decreased heart rate and blood pressure and increased salivary, GI, and bronchial glandular secretions. Table 19-1 lists the functions of direct- and indirect-acting cholinergic agonists.

Direct-Acting Cholinergic Agonists

Many drugs classified as **direct-acting cholinergic agonists** are primarily selective to the muscarinic receptors but are

TABLE 19-1 EFFECTS OF CHOLINERGIC AGONISTS

BODY TISSUE	RESPONSE
Cardiovascular*	Decreases heart rate, lowers blood pressure because of vasodilation, and slows conduction of atrioventricular node.
Gastrointestinal†	Increases tone and motility of smooth muscle of stomach and intestine. Increases peristalsis and relaxes sphincter muscles.
Genitourinary	Contracts muscles of the urinary bladder, increases tone of ureters, and relaxes bladder's sphincter muscles. Stimulates urination.
Ocular†	Increases pupillary constriction, or miosis (pupil becomes smaller) and increases accommodation (flattening or thickening of eye lens for distant or near vision).
Glandular*	Increases salivation, perspiration, and tears.
Bronchial (lung)*	Stimulates bronchial smooth muscle contraction and increases bronchial secretions.
Striated muscle†	Increases neuromuscular transmission and maintains muscle strength and tone.

*Tissue responses to large doses of cholinergic agonists.
†Major tissue responses to normal doses of cholinergic agonists.

nonspecific because the muscarinic receptors are located in the smooth muscle of the GI and genitourinary tracts, glands, and heart. Bethanechol chloride (Urecholine), a direct-acting cholinergic agonist, acts on the muscarinic (cholinergic) receptor and is used primarily to increase micturition (urination) in the treatment of urinary retention and neurogenic bladder. Metoclopramide HCl (Reglan) is a direct-acting cholinergic agonist that is usually prescribed to treat gastroesophageal reflux disease (GERD). Metoclopramide accelerates gastric emptying time. Prototype Drug Chart 19-1 details the pharmacologic behavior of bethanechol, which is a classic cholinergic agonist.

Pharmacokinetics Bethanechol chloride (Urecholine) is poorly absorbed from the GI tract. The percentage of protein-binding and the half-life are unknown. The drug is most likely excreted in the urine.

Pharmacodynamics The principal use of bethanechol is to promote micturition by stimulating the muscarinic cholinergic receptors in the detrusor muscle to contract the bladder and produce urine output. The patient voids approximately 30 minutes to 1.5 hours after taking an oral dose of bethanechol because of the increased tone of the detrusor muscle. Bethanechol also increases peristalsis in the GI tract. The drug should be taken on an empty stomach. It should not be administered by injection.

Side Effects and Adverse Reactions

Mild to severe side effects of most muscarinic agonists such as bethanechol include hypotension, bradycardia, blurred vision, excessive salivation, increased gastric acid secretion, abdominal cramps, diarrhea, bronchoconstriction, and, in some cases, cardiac dysrhythmias. This group of agents should be prescribed cautiously for patients with low blood pressure and heart rates. Muscarinic agonists are contraindicated for patients with intestinal or urinary tract obstruction, severe bradycardia, and for those with active asthma.

Direct-Acting Cholinergics: Eye

Pilocarpine is a direct-acting cholinergic agonist that constricts the pupils of the eyes, thus opening the canal of Schlemm to promote drainage of aqueous humor (fluid). This drug is used to treat glaucoma by relieving fluid (intraocular) pressure in the eye and to promote miosis in eye surgery and examinations. An oral form of pilocarpine is used to relieve xerostomia (dry mouth). Pilocarpine also acts on the nicotinic receptor, as does carbachol. Both agents are discussed in more detail in Chapter 49.

Indirect-Acting Cholinergic Agonists

The **indirect-acting cholinergic agonists** do not act on receptors; instead they inhibit or inactivate the enzyme cholinesterase, permitting acetylcholine to accumulate at the receptor sites (see Figure 19-2, *B*). This action gives them

PROTOTYPE DRUG CHART 19-1

Bethanechol Chloride

Drug Class
Cholinergic: parasympathomimetic
Trade Names: Urecholine
Pregnancy Category: C

Dosage
A: PO: 10-50 mg t.i.d./q.i.d.; *max:* 200 mg/d

Contraindications
Contraindicated: Intestinal or urinary tract obstruction, severe bradycardia, hypotension, COPD, asthma, peptic ulcer, parkinsonism.

Drug-Lab-Food Interactions
Drug: Decreases bethanechol effect with antidysrhythmics (e.g., procainamide); ganglionic blocking agents (e.g., mecamylamine) cause significant hypotension and false test results (amylase, lipase); atropine counteracts bethanechol action
Lab: Increases AST, bilirubin, amylase, lipase

Pharmacokinetics
Absorption: PO: Poorly absorbed
Distribution: PB: UK
Metabolism: $t\frac{1}{2}$: UK
Excretion: In urine

Pharmacodynamics
PO: Onset: 0.5-1.5 h
Peak: 1-2 h
Duration: 4-6 h

Therapeutic Effects/Uses
To treat urinary retention
Mode of Action: Stimulates the cholinergic (muscarinic) receptors; promotes contraction of the bladder; increases GI secretions and peristalsis, pupillary constriction, and bronchoconstriction

Side Effects
Nausea, vomiting, diarrhea, abdominal cramps, salivation, sweating, flushing, frequent urination, blurred vision, miosis

Adverse Reactions
Orthostatic hypotension, bradycardia, muscle weakness
Life-threatening: Acute asthma attack, heart block, circulatory collapse, cardiac arrest

A, Adult; *AST,* aspartate aminotransferase; *b.i.d.,* two times a day; *COPD,* chronic obstructive pulmonary disease; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *q.i.d.,* four times a day; *subQ,* subcutaneous; $t\frac{1}{2}$, half-life; *t.i.d.,* three times a day; *UK,* unknown.

the name *cholinesterase (ChE) inhibitors*, *acetylcholinesterase (AChE) inhibitors*, or *anticholinesterases*, of which there are two types: reversible and irreversible.

Nursing Process
Patient-Centered Collaborative Care

Cholinergic Agonist, Direct Acting: Bethanechol (Urecholine)

Assessment
- Assess baseline vital signs for future comparison.
- Assess urine output (should be >1500 mL/d).
- Obtain patient history of health problems such as peptic ulcer, urinary obstruction, or asthma. Cholinergic agonists can aggravate symptoms of these conditions.

Nursing Diagnoses
- Impaired urinary elimination related to urinary retention
- Anxiety related to wheezing
- Risk for impaired skin integrity related to rash
- Ineffective breathing pattern related to excess mucous secretions in lungs

Planning
- Patient will have increased bladder tone after taking cholinergic agonists.

Nursing Interventions
- Monitor patient's vital signs. Heart rate and blood pressure decrease when large doses of cholinergics are taken. Orthostatic hypotension is a side effect of a cholinergic agonist such as bethanechol.
- Record fluid intake and output. Decreased urinary output should be reported because it may be related to urinary obstruction.
- Give cholinergic agonists 1 hour before or 2 hours after meals. If patient complains of gastric pain, the drug may be given with meals.
- Check serum amylase, lipase, aspartate aminotransferase, and bilirubin levels. These laboratory values may increase slightly when taking cholinergic agonists.
- Observe patient for side effects such as gastric pain or cramping, diarrhea, increased salivary or bronchial secretions, bradycardia, and orthostatic hypotension.

- Auscultate breath sounds for rales (cracking sounds from fluid congestion in lungs) or rhonchi (rough sounds resulting from mucous secretions in lungs). Cholinergic agonists can increase bronchial secretions.
- Have IV atropine sulfate (0.6 mg to 1.2 mg) available as an antidote for cholinergic overdose. Early signs of overdosing include flushing, salivation, sweating, nausea, and abdominal cramps.
- Increase bathing frequency and linen change when needed. Diaphoresis (excessive perspiration) may occur.
- Monitor for possible cholinergic crisis (overdose) including symptoms of muscular weakness and increased salivation.

Patient Teaching

- Teach patient to take the cholinergic agonist as prescribed. Compliance with the drug regimen is essential.
- Direct patient to report severe side effects, such as profound dizziness or a decrease in heart rate below 60 beats/min.
- Teach patient to arise from a lying position slowly to avoid dizziness. This is most likely a result of orthostatic hypotension.
- Encourage patient to maintain effective oral hygiene if excess salivation occurs.
- Advise patient to report any difficulty in breathing as a result of respiratory distress.

Cultural Considerations

- Use both hands to show respect when offering a prescription, instructions, or pamphlets to Asians and Pacific Islanders.
- Recognize the importance of including women in decision making and disseminating health information. The extended family structure is important for teaching health strategies and providing support.

Evaluation

- Determine the effectiveness of the cholinergic agonist or anticholinesterase drug.
- Evaluate the stability of patient's vital signs, and note the presence of side effects or adverse reactions.

The function of the enzyme cholinesterase is to break down into choline and acetic acid. A small amount of cholinesterase can break down a large amount of acetylcholine in a short period. A cholinesterase inhibitor drug binds with cholinesterase, allowing acetylcholine to activate the muscarinic and nicotinic cholinergic receptors. This action permits skeletal muscle stimulation, which increases the force of muscular contraction. Because of this action, cholinesterase inhibitors are useful to increase muscle tone for patients with myasthenia gravis (a neuromuscular disorder). By increasing acetylcholine, additional effects occur, such as increase in GI motility, bradycardia, miosis, bronchial constriction, and increased micturition.

The primary use of reversible cholinesterase inhibitors is to treat myasthenia gravis; another use is to treat Alzheimer's disease. The primary clinical indication for irreversible cholinesterase inhibitors is glaucoma.

Reversible Cholinesterase Inhibitors

Reversible cholinesterase inhibitors are used (1) to produce pupillary constriction in the treatment of glaucoma and (2) to increase muscle strength in patients with myasthenia gravis. Drug effects persist for several hours. Drugs used to increase muscular strength in myasthenia gravis include neostigmine (Prostigmin [short-acting]), pyridostigmine bromide (Mestinon [moderate-acting]), ambenonium chloride (Mytelase [long-acting]), and edrophonium chloride (Tensilon [short-acting for diagnostic purposes]). These drugs are discussed in more detail in Chapter 24. A reversible anticholinesterase drug is physostigmine (Antilirium) or ophthalmic form (Isopto Eserine). Physostigmine is used as an antidote for atropine to reverse anticholinergic toxicity. Ophthalmic agents are further discussed in Chapter 49.

Side Effects

Caution for reversible cholinesterase inhibitors is required for patients who have bradycardia, asthma, peptic ulcers, or hyperthyroidism. Cholinesterase inhibitors are contraindicated for patients with intestinal or urinary obstruction.

Irreversible Cholinesterase Inhibitors

Irreversible cholinesterase inhibitors are potent agents because of their long-lasting effect. The enzyme cholinesterase must be regenerated before the drug effect diminishes—a process that may take days or weeks. These drugs are used to produce pupillary constriction.

Table 19-2 lists examples of cholinergic drugs and their standard dosages and common uses.

ANTICHOLINERGICS

Drugs that inhibit the actions of acetylcholine by occupying the acetylcholine receptors are called **anticholinergics** or **parasympatholytics.** Other names used for anticholinergics are **cholinergic blocking agents,** *cholinergic or muscarinic antagonists, antiparasympathetic agents, antimuscarinic agents,* and *antispasmodics.* The major body tissues and organs affected by the anticholinergic group of drugs are the heart, respiratory tract, GI tract, urinary bladder, eyes, and exocrine glands. By blocking the parasympathetic nerves, the sympathetic (adrenergic) nervous system dominates. Anticholinergics and adrenergic agonists produce many of the same responses.

Anticholinergic and cholinergic agonists have opposite effects. The major responses to anticholinergics are a decrease in GI motility, a decrease in salivation, dilation of pupils **(mydriasis),** and an increase in pulse rate. Other effects of

TABLE 19-2 CHOLINERGIC AGONISTS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Direct-Acting Cholinergic Agonists		
bethanechol Cl (Urecholine)	See Prototype Drug Chart 19-1.	
metoclopramide HCl (Reglan)	A: PO: 5-10 mg q8h PRN	For GERD, gastroparesis, and nausea. Central dopamine receptor antagonist. Increases gastric emptying time. Pregnancy category: B; PB: 30%; t½: 2.5-6 h
carbachol (Miostat)	Ophthalmic: 0.75%-3%, 1-2 gtt, 3 daily	To reduce IOP, miosis. See Chapter 49.
pilocarpine HCl (Pilocar)	Ophthalmic: 0.5%-4%, 1 gt	To reduce IOP, miosis. See Chapter 49.
Cholinesterase Inhibitor		
donepezil HCl (Aricept); rivastigmine (Exelon)	See Chapter 23, Table 23-6.	
Indirect-Acting Cholinergics or Cholinesterase Inhibitors for the Eye		
demecarium bromide (Humorsol)	0.125%-0.25%, 1 gt q12-48h	To reduce IOP in glaucoma; long-acting miotic. See Chapter 49.
echothiophate iodide (Phospholine Iodide)	0.03%-0.25%, 1 gt daily or b.i.d.	To reduce IOP; long-acting miotic. See Chapter 49.
isoflurophate (Floropryl)	0.25%, ointment q8-72h	To treat glaucoma. Apply to the conjunctival sac. See Chapter 49.
Reversible Cholinesterase Inhibitors: Myasthenia Gravis		
ambenonium Cl (Mytelase)	A: PO: 2.5-5 mg t.i.d./q.i.d.; dose may be increased; maint: 50-75 mg t.i.d./q.i.d.	To increase muscle strength in myasthenia gravis; long-acting. May be used with glucocorticoids. Pregnancy category: C; PB: UK; t½: UK
edrophonium Cl (Tensilon)	A: IV: 2 mg; then 8 mg if no response IM: 10 mg; may repeat with 2 mg in 30 min C: <34 kg: IV: 1 mg; repeat in 30-45 sec if no response; *max:* 5 mg C: >34 kg: IV: 2 mg; repeat with 1 mg if no response; *max:* 10 mg	To diagnose myasthenia gravis; very short-acting. Pregnancy category: C; PB: UK; t½: 1.2-2 h
neostigmine methylsulfate (Prostigmin)	A: 15 mg t.i.d.; gradually increase to maintenance dose of 150 mg; *max:* 375 mg/d A: IM/IV: 0.5-2.5 mg q1-3h; *max:* 10 mg/d C: IM/IV: 0.01-0.04 mg/kg q2-4h	To increase muscle strength in myasthenia gravis; short-acting. Used also to prevent or treat postoperative urinary retention. Pregnancy category: C; PB: 15%-25%; t½: 1-1.5 h
physostigmine salicylate (Antilirium); (Isopto Eserine Salicylate-ophthalmic form)	A: IV/IM: 0.5-2 mg/dose, repeat q10-30min PRN; C: IV: 0.02 mg/kg/dose, repeat q5-10 min PRN; *max:* 2 mg total A: 0.25% to 0.5%, 1-2 gtt daily or q.i.d.; max: 8 gtt/d	To reverse anticholinergic toxicity and to reduce IOP, miosis; short-acting. Pregnancy category: C; PB: UK; t½: 15-40 min
pyridostigmine bromide (Mestinon)	A: PO: 60-120 mg t.i.d./q.i.d.; maint: 600 mg/d in 3-4 divided doses; SR: 180-540 mg daily or b.i.d. IM/IV: 2 mg q2-3h C: PO: 7 mg/kg/d in 5-6 divided doses	To increase muscle strength in myasthenia gravis. Prevents destruction of the neurotransmitter acetylcholine. Pregnancy category: C; PB: 10%; t½: 3-4 h
Antidote for Irreversible and Reversible Cholinesterase Inhibitors		
pralidoxime Cl (Protopam)	A: IV: 1-2 g in 100 mL of saline solution infused over 15-30 min; follow with 250 mg q5min PRN	To treat overdose of a cholinesterase inhibitor for myasthenia gravis and to treat overdose of organophosphate pesticides that cause muscle paralysis. Pregnancy category: C; PB: UK; t½: 1-2.7 h

A, Adult; *a.c.,* before meals; *b.i.d.,* two times a day; *C,* child; *d,* day; *GERD,* gastroesophageal reflux disease; *GI,* gastrointestinal; *gt,* drop; *gtt,* drops; *h,* hour; *IM,* intramuscular; *IOP,* intraocular pressure; *IV,* intravenous; *maint,* maintenance; *PB,* protein-binding; *p.c.,* after meals; *PO,* by mouth; *PRN,* as needed; *q.i.d.,* four times a day; *sec,* second; *SR,* sustained-release; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *>,* greater than; *<,* less than.

anticholinergics include decreased bladder contraction, which can result in urinary retention, and decreased rigidity and tremors related to neuromuscular excitement. An anticholinergic can act as an antidote to the toxicity caused by cholinesterase inhibitors and organophosphate ingestion. The various effects of anticholinergics are described in Table 19-3.

Muscarinic receptors are a type of *cholinergic receptor* involved in tissue and organ responses to anticholinergics, because anticholinergics inhibit the actions of acetylcholine by occupying these receptor sites. Figure 19-3 illustrates this action of anticholinergic drugs. Anticholinergic drugs may also block the effect of direct-acting parasympathomimetics such as bethanechol and pilocarpine and of indirect-acting parasympathomimetics such as physostigmine and neostigmine.

TABLE 19-3 EFFECTS OF ANTICHOLINERGIC DRUGS

BODY TISSUES	RESPONSES
Cardiovascular	Increases heart rate with large doses. Small doses can decrease heart rate.
Gastrointestinal (GI)	Relaxes smooth muscle tone of GI tract, decreasing GI motility and peristalsis. Decreases gastric and intestinal secretions.
Urinary tract	Relaxes bladder detrusor muscle and increases constriction of internal sphincter. Urinary retention can result.
Ocular	Dilates pupils (mydriasis) and paralyzes ciliary muscle (cycloplegia), causing a decrease in accommodation.
Glandular	Decreases salivation, perspiration, and bronchial secretions.
Bronchial	Dilates the bronchi, and decreases bronchial secretions.
Central nervous system	Decreases tremors and rigidity of muscles. Drowsiness, disorientation, and hallucinations can result from large doses.

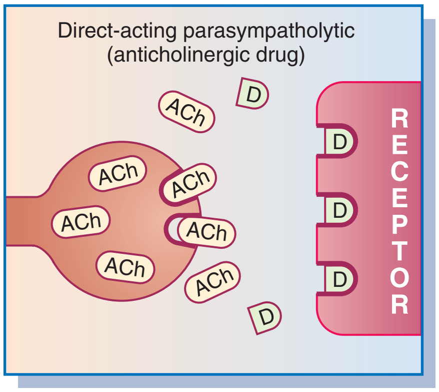

FIGURE 19–3 Anticholinergic response. The anticholinergic drug occupies the receptor sites, blocking acetylcholine. *ACh,* Acetylcholine; *D,* anticholinergic drug.

Atropine

Atropine sulfate, first derived from the belladonna plant *(Atropa belladonna)* and purified in 1831, is a classic anticholinergic, or muscarinic antagonist drug. Scopolamine was the second belladonna alkaloid produced. Atropine and scopolamine act on muscarinic receptors, but they have little effect on nicotinic receptors. Atropine is useful primarily (1) as a preoperative medication to decrease salivary secretions and (2) as an agent to increase heart rate when bradycardia is present. Atropine or auto-injector (Atropen) can also be used as an antidote for muscarinic agonist poisoning caused by an overdose of a cholinesterase inhibitor or a muscarinic drug such as bethanechol. However, if a patient takes atropine or an atropine-like drug (e.g., antihistamine), side effects can occur. Prototype Drug Chart 19-2 details the pharmacologic behavior of atropine.

Synthetic anticholinergic drugs are also used as antispasmodics to treat peptic ulcers and intestinal spasticity. One example is propantheline bromide (Pro-Banthine), which has been available for several decades. It decreases gastric secretions and GI spasms. Since the introduction of the histamine (H_2) blockers, anticholinergic agents such as propantheline are rarely used to decrease gastric secretions.

Pharmacokinetics Atropine sulfate is well absorbed orally and parenterally. It crosses the blood-brain barrier and exerts its effect on the central nervous system (CNS). The protein binding is unknown. It crosses the placenta. Atropine has a short half-life, so there is little cumulative effect. Most of the absorbed atropine is excreted in the urine (75% to 95%).

Pharmacodynamics Atropine sulfate blocks acetylcholine by occupying the muscarinic receptor. It increases the heart rate by blocking vagus stimulation and promotes dilation of the pupils by paralyzing the iris sphincter. The two most frequent uses of atropine are to decrease salivation and respiratory secretions preoperatively and to treat sinus bradycardia by increasing the heart rate. Atropine also is used ophthalmically for mydriasis and cycloplegia before eye exams and to treat inflammation of the iris (iritis) and uveal tract.

Its onset of action orally is between 0.5 to 1 hour and peaks at 1 hour. For the IM route, the onset of action is 10 to 30 minutes and peaks at 30 minutes. The duration for oral and IM routes is 4 hours; via the IV route, the onset of action is immediate and peak action is at 2 to 4 minutes.

Side Effects and Adverse Reactions

The common side effects of atropine and atropine-like drugs include dry mouth, decreased perspiration, blurred vision, tachycardia, constipation, and urinary retention. Other side effects and adverse reactions are nausea, headache, dry skin, abdominal distention, hypotension or hypertension, impotence, photophobia (intolerance of bright light), and coma.

Antiparkinson-Anticholinergic Drugs

At one time atropine was given to patients with Parkinson's disease to decrease salivation and drooling. It was also found to have some effect on the motor manifestation of this disease by decreasing tremors and rigidity. Additional studies indicate that anticholinergic (antimuscarinic) agents affect the CNS as well as the parasympathetic nervous system. These anticholinergic drugs affect the CNS by suppressing the

PROTOTYPE DRUG CHART 19-2

Atropine

Drug Class

Anticholinergic: parasympatholytic
Trade Name: Atropine
Pregnancy Category: C

Dosage

To treat bradycardia:
A: IV: 0.5-1 mg, repeat q5min PRN up to 2 mg
C: IV: 0.01-0.03 mg/kg/dose; *max:* 0.4 mg/dose
Preoperatively:
A: PO: 2 mg 30-60 min before anesthesia
C >20 kg: IV/IM: 0.2-1 mg before anesthesia

Contraindications

Narrow-angle glaucoma, obstructive GI disorders, paralytic ileus, ulcerative colitis, tachycardia, benign prostatic hypertrophy, myasthenia gravis, myocardial ischemia, hypersensitivity
Caution: Renal or hepatic disorders, COPD, heart failure

Drug-Lab-Food Interactions

Drug: Increases anticholinergic effect with phenothiazines, antihistamines, tricyclic antidepressants, amantadine, quinidine; high-dose anticholinergics may decrease effects of carbidopa/levodopa by delaying GI absorption; anticholinergics may enhance therapeutic effects at therapeutic doses.

Pharmacokinetics

Absorption: PO/IM: Well absorbed
Distribution: PB: UK; crosses the placenta
Metabolism: t½: 2-3 h
Excretion: 75% excreted in urine

Pharmacodynamics

PO: Onset: 0.5-1 h
Peak: 1 h
Duration: 4 h
IM: Onset: 10-30 min
Peak: 0.5 h
Duration: 4 h
IV: Onset: Immediate
Peak: 5 min
Duration: UK
Instill: Onset: 20-30 min
Peak: 30-40 min
Duration: days

Therapeutic Effects/Uses

Preoperative medication to reduce salivation, to increase heart rate for bradycardia, and to dilate pupils for ocular diagnostic exams
Mode of Action: Inhibits acetylcholine by occupying the receptors; increases heart rate by blocking vagus stimulation; promotes pupil dilation by blocking iris sphincter muscle

Side Effects

Dry mouth, nausea, headache, constipation, dry skin, flushing, mydriasis, blurred vision, anxiety, photophobia, palpitations, urinary retention

Adverse Reactions

Tachycardia, hypotension
Life-threatening: Ventricular fibrillation, Stevens-Johnson syndrome, coma

A, Adult; *C,* child; *COPD,* chronic obstructive pulmonary disease; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *instill,* instillation; *IV,* intravenous; *MAOI,* monoamine oxidase inhibitor; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *t½,* half-life; *UK,* unknown; >, greater than.

tremors and muscular rigidity of parkinsonism, but they have little effect on mobility and muscle weakness. As a result of these findings, several anticholinergic drugs were developed for the treatment of Parkinson's disease (e.g., trihexyphenidyl hydrochloride [Artane], biperiden [Akineton], and benztropine [Cogentin]). These drugs can be used alone in early stages of parkinsonism. They may be used in combination with levodopa/carbidopa to control parkinsonism or used alone to treat pseudoparkinsonism, which results from the side effects of the phenothiazines in antipsychotic drugs. Drugs used to treat parkinsonism are described in more detail in Chapter 23. Prototype Drug Chart 19-3 lists the drug data related to benztropine (Cogentin), which is used for parkinsonism.

Pharmacokinetics Benztropine is well absorbed from the GI tract. Its protein-binding percentage and half-life are unknown. It is excreted in the urine.

Pharmacodynamics Benztropine decreases involuntary movement and diminishes the signs and symptoms of tremors and muscle rigidity that occur with Parkinson's disease and pseudoparkinsonism. It is available as an oral tablet and as parenteral intramuscular and intravenous injections. Alcohol and other CNS depressants potentiate sedation. Anticholinergics, phenothiazines, and tricyclic antidepressants may increase the anticholinergic effects of benztropine. The side effects are similar to other anticholinergic drugs.

Nursing Process

Patient-Centered Collaborative Care

Anticholinergic Drugs: Atropine

Assessment

- Obtain baseline vital signs for future comparison. Tachycardia is a side effect that occurs with large doses of anticholinergics such as atropine sulfate.

PROTOTYPE DRUG CHART 19-3

Benztropine

Drug Class
Antiparkinson: anticholinergic agent
Trade Names: Cogentin
Pregnancy Category: C

Dosage
Parkinsonism: A: PO: 0.5-6 mg/d h.s.; *max:* 8 mg/d
Extrapyramidal symptoms except tardive dyskinesia (drug induced)
A: PO: 1-4 mg q.d./b.i.d.

Contraindications
Closed-angle glaucoma, tardive dyskinesia, psychosis, dementia, myasthenia gravis
Caution: Tachycardia, cardiac disease, autonomic neuropathy, benign prostatic hypertrophy, children younger than 3 years of age

Drug-Lab-Food Interactions
Drug: Increases anticholinergic effect with phenothiazines, tricyclic antidepressants, and other anticholinergics

Pharmacokinetics
Absorption: PO: Well absorbed
Distribution: PB: UK
Metabolism: t½: UK
Excretion: In urine

Pharmacodynamics
PO: Onset: 1 h
Peak: 2-3 h
Duration: 6-10 h

Therapeutic Effects/Uses
To decrease involuntary symptoms of parkinsonism or drug-induced parkinsonism
Mode of Action: Blocks cholinergic (muscarinic) receptors, thus decreasing acetylcholine to reduce excess cholinergic activity (involuntary movements). Also, blocks dopamine reuptake to prolong dopamine effects and decrease involuntary movement.

Side Effects
Nausea, vomiting, dry mouth, constipation, restlessness, flushing, dizziness, blurred vision, photophobia, pupil dilation, amnesia, confusion, depression, hallucinations, anhidrosis (decreased sweating), weakness, hyperthermia, paresthesia

Adverse Reactions
Tachycardia, palpitations, urinary retention
Life-threatening: Paralytic ileus

A, Adult; *b.i.d.,* two times a day; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *q.d.,* once daily; *t½,* half-life; *UK,* unknown.

- Assess urine output. Urinary retention may occur.
- Check patient's medical history. Atropine and atropine-like drugs are contraindicated if patient has narrow-angle glaucoma, obstructive GI disorder, paralytic ileus, ulcerative colitis, benign prostatic hypertrophy, or myasthenia gravis.
- Obtain patient's drug history. Phenothiazines and antidepressants increase the effect of anticholinergics.

Nursing Diagnoses

- Impaired urinary elimination related to urinary retention
- Impaired oral mucous membranes related to decreased oral secretions
- Risk for injury related to acute confusion
- Risk for constipation related to decreased peristalsis secondary to atropine side effects

Planning

- Patient's secretions will be decreased before surgery.
- Patient will not have side effects that may become a health problem.

Nursing Interventions

- Monitor patient's vital signs. Report if tachycardia occurs.
- Determine fluid intake and output. Encourage patient to void before taking the medication. Report decreased urine output. Anticholinergics can cause urinary retention. Maintain adequate fluid intake.
- Assess bowel sounds. Absence of bowel sounds may indicate paralytic ileus resulting from a decrease in GI motility (peristalsis).
- Examine for constipation caused by decrease in GI motility. Encourage patient to ingest foods that are high in fiber, to drink adequate amounts of fluids, and to exercise if able.
- Use bed alarms for patients who are confused and debilitated. Atropine could cause central nervous system stimulation (excitement, confusion) or drowsiness.
- Provide mouth care. Atropine decreases oral secretions and can cause dryness.
- Administer IV atropine undiluted or prefer diluted in 10 mL of sterile water. Rate of administration is 1 mg or fraction thereof/min.

Patient Teaching

General

- Direct patient to avoid hot environments and excess physical exertion. Elevations in body temperature can result from diminished sweat gland activity.
- Teach patient with narrow-angle glaucoma to avoid atropine-like drugs. Anticholinergics cause mydriasis and increase intraocular pressure. Instruct patient to check labels on over-the-counter (OTC) drugs to determine whether they are contraindicated for glaucoma.
- Instruct patient not to drive a motor vehicle or participate in activities that require alertness. Drowsiness is common.
- Tell patient with mydriasis following an eye examination to use sunglasses in bright light because of photophobia.

Side Effects

- Advise patient of common side effects such as dry mouth, decrease in urination, and constipation that occur as a result of anticholinergic use.
- Direct patient to increase fluid intake and consumption of high-fiber foods to prevent constipation when taking anticholinergics for a prolonged period.
- Instruct patient to urinate before taking the anticholinergic. Urinary retention can be a problem.
- Advise patient to report a marked decrease in urine output.
- Suggest that patient use hard candy, ice chips, or chewing gum. Maintain effective oral hygiene if patient's mouth is dry. Anticholinergics decrease salivation.
- Encourage patient to use eye drops to moisten dry eyes that result from decreased lacrimation (tearing).

Cultural Considerations

- Obtain an interpreter when necessary. Do not rely on family members, who may not fully disclose because of honor, guilt, or lack of understanding of medical terminology.
- Ask open-ended questions, and have patients demonstrate rather than verbalize their understanding of treatments. Because politeness may prevail, do not assume that a positive response means a definite yes.

Evaluation

- Evaluate patient's response to the anticholinergic.
- Determine whether constipation, urinary retention, or increased pulse rate is or remains a problem.

PROTOTYPE DRUG CHART 19-4

Tolterodine Tartrate

Drug Class

Antimuscarinic agent: anticholinergic
Trade Names: Detrol, Detrol LA
Pregnancy Category: C

Dosage

A: PO: 2 mg b.i.d. or 4 mg/day SR

Contraindications

Hypersensitivity, urinary retention, gastric retention, uncontrolled narrow-angle glaucoma, lactation

Caution: Controlled narrow-angle glaucoma, cardiovascular disease, urinary bladder outflow obstruction, pyloric stenosis or other GI obstructive disorders, paralytic ileus, ulcerative colitis, renal or hepatic dysfunction

Drug-Lab-Food Interactions

Drug: Increased effects with amantadine, amoxapine, bupropion, clozapine, cyclobenzaprine, disopyramide, maprotiline, olanzapine, orphenadrine, H_1 blockers, phenothiazines, and tricyclic antidepressants; decreased effects with azole antifungals (e.g., ketoconazole) or macrolide antibiotics (e.g., erythromycin), cyclosporine, and fluoxetine

Food: Grapefruit juice may increase drug levels

Pharmacokinetics

Absorption: GI absorption decreased with food
Distribution: PB: 96%
Metabolism: t½: 2-4 h
Excretion: Urine and feces

Pharmacodynamics

PO: Onset: UK
Peak: 1-2 h
Duration: UK

Therapeutic Effects/Uses

To decrease urinary frequency, urgency, and incontinence
Mode of Action: Blocks cholinergic (muscarinic) receptors selectively in urinary bladder

Side Effects

Dry mouth, eyes, and skin; headache, dizziness, vertigo, nervousness, nausea, vomiting, diarrhea, abdominal pain, constipation, dyspepsia, flatulence, dysuria, weight gain, arthralgia, urinary retention

Adverse Reactions

Bronchitis, visual abnormalities, chest pain, hypertension

A, Adult; *b.i.d.,* two times a day; *GI,* gastrointestinal; *H1,* histamine 1; *h,* hour; *PB,* protein binding; *PO,* by mouth; *SR,* sustained-release; *t½,* half-life; *UK,* unknown; *URI,* upper respiratory tract infection; *UTI,* urinary tract infection.

TABLE 19-4 ANTICHOLINERGICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Anticholinergics: Gastrointestinal or Cholinergic Blockers		
atropine sulfate	See Prototype Drug Chart 19-2.	
dicyclomine HCl (Bentyl)	A: PO: 20-40 mg q.i.d.; *max:* 160 mg/d IM: 10-20 mg q6h; *max:* 80 mg/d C >2 y: PO: 10 mg t.i.d./q.i.d.; *max:* 40 mg/d	Treatment of IBS. Avoid use in patients with narrow-angle glaucoma, severe ulcerative colitis, and paralytic ileus. Pregnancy category: B; PB: UK; t½: 9-10 h
glycopyrrolate (Robinul)	GI disorders: A: PO: 1-2 mg b.i.d./t.i.d.; *max:* 6 mg/d IM/IV: 0.1-0.2 mg t.i.d./q.i.d. Preoperative: A: IM: 4 mcg/kg 30 min-1 h before surgery	Presurgery to reduce secretions and for peptic ulcer. Contraindicated in patients with narrow-angle glaucoma, obstructive GI tract, and ulcerative colitis. Pregnancy category: B; PB: UK; t½: 0.5-2 h
hyoscyamine SO_4 (Cystospaz, Anaspaz)	A: PO/SL: 0.125-0.25 mg q4h PRN SR: 0.375-0.75 mg/q12h subQ/IM/IV: 5 mcg/kg 30-60 min preop C: 2-10 y: 0.0625-0.125 mg q4h PRN	Treatment of peptic ulcer and IBS. Controls gastric secretion and spastic bladder. Contraindicated in patients with narrow-angle glaucoma and severe ulcerative colitis. Pregnancy category: C; PB: 50%-60%; t½: 3.5 h
methscopolamine bromide (Pamine)	A: PO: 2.5-5 mg a.c. and h.s.; *max:* 12.5 mg/d	Has been used in treatment of peptic ulcer, IBS. Now used to relieve allergic rhinitis, sinusitis, and common cold. Avoid use in patients with prostatic hypertrophy and ileus. Pregnancy category: C; PB: UK; t½: UK
propantheline bromide (Pro-Banthine)	A: PO: 15 mg a.c. t.i.d.; 30 mg h.s. Older adults: 7.5 mg a.c. t.i.d.	Antispasmodic for peptic ulcer. Contraindicated in glaucoma, myasthenia gravis, and prostatic hypertrophy. Pregnancy category: C; PB: UK; t½: 9 h
scopolamine (Transderm Scōp)	Preoperative: subQ/IM/IV: 0.3-0.6 mg C: subQ: 0.1-0.3 mg; Motion sickness: A: PO: 250-800 mcg 1 h before needed; transdermal patch: 1.5 mg patch behind ear q72h	For preanesthetic drug, IBS, motion sickness, and delirium. Contraindicated in patients with narrow-angle glaucoma, obstructive GI disease, severe ulcerative colitis, and paralytic ileus. Pregnancy category: C; PB: 30%; t½: 8 h
Cholinergic Antagonists: Eye		
cyclopentolate HCl (Cyclogyl)	0.5%-2% sol, 1-2 gtt	For mydriasis and cycloplegia for eye examination. See Chapter 49.
homatropine (Isopto Homatropine)	2%-5% sol, 1-2 gtt	For mydriasis and cycloplegia (paralysis of ciliary muscle resulting in loss of accommodation) for eye examination. See Chapter 49.
tropicamide (Mydriacyl Ophthalmic)	0.5%-1% sol, 1-2 gtt	For mydriasis and cycloplegia for eye examination. See Chapter 49.
Anticholinergic-Antiparkinson Drugs		
benztropine mesylate (Cogentin)	See Prototype Drug Chart 19-3.	
biperiden lactate (Akineton)	Parkinsonism: A: PO: 2 mg t.i.d./q.i.d.; *max:* 16 mg/d	Treatment of parkinsonism and drug-induced extrapyramidal syndrome. Pregnancy category: C; PB: UK; t½: 6-10 h; See Chapter 23.
trihexyphenidyl HCl (Artane)	Parkinsonism: A: PO: 1 mg initially, increase to 6-10 mg/d, usually t.i.d with meals and h.s. A: PO: Extended-release: 5-10 mg after breakfast Drug-induced extrapyramidal syndrome: A: PO: 1 mg/d, increase to 5-15 mg/d in divided doses	Treatment of parkinsonism and drug-induced extrapyramidal syndrome. Pregnancy category: C; PB: UK; t½: UK; see Chapter 23.
Anticholinergic–Antimuscarinic Drugs		
tolterodine tartrate (Detrol, Detrol LA)	See Prototype Drug Chart 19-4.	
Others		
ipratropium bromide (Atrovent)	A: Inhal: 2 inhal q.i.d.; *max:* 12 inhal/d	Anticholinergic bronchodilator to treat chronic obstructive pulmonary disease by blocking action of acetylcholine at bronchial smooth muscle sites, promoting bronchodilation. Pregnancy category: B; PB: UK; t½: 2 h. See Chapter 41.

Anticholinergics for Treating Motion Sickness

The effects of anticholinergics on the CNS benefit patients who are prone to motion sickness. An example of such an anticholinergic, classified as an antihistamine for motion sickness, is scopolamine. It is available topically as a skin patch (Transderm Scōp) that is placed behind the ear. Prevention of motion sickness is also provided via wrist bands and ginger, including ginger gum or candy. Transdermal scopolamine is delivered over 3 days and is frequently prescribed for activities such as flying, cruising on the water, and bus or automobile trips. Other drugs classified as antihistamines for motion sickness are dimenhydrinate (Dramamine), cyclizine (Marzine), and meclizine hydrochloride (Antivert). Most of these drugs can be purchased OTC, with the exception of Transderm Scōp.

Examples of anticholinergic drugs and their dosages and common uses are found in Table 19-4. Dosages may vary according to age, sex, and weight. Because anticholinergic drugs can increase intraocular pressure, they should not be administered to patients diagnosed with glaucoma (Prototype Drug Chart 19-4).

Side Effects and Adverse Reactions

Side effects of antihistamines used as anticholinergics include dry mouth, visual disturbances (especially blurred vision resulting from pupillary dilation), constipation secondary to decreased GI peristalsis, urinary retention related to decreased bladder tone, tachycardia (when taken in large doses), hypotension, skin rash, muscle weakness, and flushing.

CRITICAL THINKING CASE STUDY

JS, a 56-year-old man, is scheduled for surgery to remove gallstones. He has been in good health, and his only other clinical problem is glaucoma. Preoperative medications, meperidine 75 mg and atropine sulfate 0.4 mg, were given intramuscularly 1 hour before surgery.

1. What are the advantages of giving atropine sulfate before surgery?
2. What are some contraindications of atropine sulfate?
3. If this patient received an atropine-like drug for several months, what assessments should be made related to its effects?
4. How does atropine sulfate differ from bethanechol chloride?

   This patient receives ophthalmic pilocarpine drops to control glaucoma.
5. How does pilocarpine differ from physostigmine? Explain your answer.
6. What patient teaching should the nurse include related to the use of pilocarpine?

NCLEX STUDY QUESTIONS

1. A patient is receiving bethanechol (Urecholine). The nurse realizes that the action of this drug is to treat which condition?
   a. Glaucoma
   b. Urinary retention
   c. Delayed gastric emptying
   d. Gastroesophageal reflux disease
2. The nurse teaches the patient receiving atropine (Atreza) to expect which side effect?
   a. Diarrhea
   b. Bradycardia
   c. Blurred vision
   d. Frequent urination
3. When benztropine (Cogentin) is ordered for a patient, the nurse acknowledges that this drug is an effective treatment for which condition?
   a. Parkinsonism
   b. Paralytic ileus
   c. Motion sickness
   d. Urinary retention
4. Dicyclomine (Bentyl) is an anticholinergic, which the nurse realizes is given to treat which condition?
   a. Mydriasis
   b. Constipation
   c. Urinary retention
   d. Irritable bowel syndrome

5. The nurse realizes that cholinergic agonists mimic which parasympathetic neurotransmitter?
   a. dopamine
   b. acetylcholine
   c. cholinesterase
   d. monoamine oxidase
6. The nurse is administering bethanechol (Urecholine), a cholinergic agonist, and should know that the expected cholinergic effects include which of the following?
   a. Increased heart rate
   b. Decreased peristalsis
   c. Decreased salivation
   d. Increased pupil constriction
7. When a patient has a cholinergic overdose from excessive dosing of bethanechol (Urecholine), the nurse anticipates administration of which drug as the antidote?
   a. atropine
   b. tolterodine
   c. benztropine
   d. metoclopramide

Answers: 1, b; 2, c; 3, a; 4, d; 5, b; 6, d; 7, a.

UNIT VI

Neurologic and Neuromuscular Agents

The nervous system is composed of all nerve tissues: brain, spinal cord, nerves, and ganglia. The purpose of the nervous system is to receive stimuli and transmit information to nerve centers for an appropriate response. There are two types of nervous system: the central nervous system and the peripheral nervous system.

The central nervous system (CNS), composed of the brain and spinal cord, regulates body functions (Figure VI-1). The CNS interprets information sent by impulses from the peripheral nervous system (PNS) and returns the instruction through the PNS for appropriate cellular actions. Stimulation of the CNS may either increase nerve cell (neuron) activity or block nerve cell activity.

The PNS consists of two divisions: the somatic nervous system (SNS) and the autonomic nervous system (ANS). The SNS is voluntary and acts on skeletal muscles to produce locomotion and respiration. The ANS, also called the visceral system, is involuntary and controls and regulates the functioning of the heart, respiratory system, gastrointestinal system, and glands. The ANS, a large nervous system that functions without our conscious control, has two subdivisions: the sympathetic and the parasympathetic nervous systems.

The sympathetic nervous system of the ANS is called the adrenergic system because its neurotransmitter is norepinephrine. The parasympathetic nervous system is called the cholinergic system because its neurotransmitter is acetylcholine. Because organs are innervated by both the sympathetic and the parasympathetic systems, they can produce opposite responses. The sympathetic response is excitability, and the parasympathetic response is inhibition.

The sympathetic and the parasympathetic nerve pathways originate from different locations in the spinal cord. These nervous systems send information by two types of nerve fibers, the preganglionic and the postganglionic, and by the ganglion between these fibers (Figure VI-2). The preganglionic nerve fiber carries messages from the CNS to the ganglion, and the postganglionic fiber transmits impulses from the ganglion to body tissues and organs.

The sympathetic nervous system is also called the thoracolumbar division of the ANS, because the preganglionic fibers originate from the thoracic (T1 to T12) and the upper lumbar (L1 and L2) segments of the spinal cord. The sympathetic preganglionic fibers are short from the spinal cord to the ganglion, and the sympathetic postganglionic fibers are long from the ganglion to the body cells. Figure VI-3 illustrates the sympathetic preganglionic fibers from the spinal cord.

The parasympathetic nervous system is called the craniosacral division of the ANS, because the preganglionic fibers

originate with cranial nerves III, VII, IX, and X from the brainstem and sacral segments S2, S3, and S4 of the spinal cord. The parasympathetic preganglionic fibers are long from the spinal cord to the ganglion, and the parasympathetic postganglionic fibers are short from the ganglion to the body cells. Figure VI-4 illustrates the parasympathetic preganglionic fibers from the spinal cord.

Drugs that stimulate and depress the CNS are discussed in Chapter 20, Central Nervous System Stimulants, and Chapter 21, Central Nervous System Depressants. Drugs used to control convulsions (Chapter 22, Anticonvulsants) are considered CNS depressants. Drugs used to treat neuromuscular disorders, such as parkinsonism, myasthenia gravis, multiple sclerosis, and Alzheimer's disease, have varying effects on the nervous system and muscles (Chapter 23, Drugs for Neurologic Disorders: Parkinsonism and Alzheimer's Disease; and Chapter 24, Drugs for Neuromuscular Disorders: Myasthenia Gravis, Multiple Sclerosis, and Muscle Spasms).

- Key Points
- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Explain the effects of stimulants on the central nervous system (CNS).
- Compare attention deficit/hyperactivity disorder and narcolepsy.
- Differentiate the action of drugs used for attention deficit/hyperactivity disorder and narcolepsy.
- Contrast the common side effects of amphetamines, anorexiants, analeptics, doxapram, and caffeine.
- Compare the pharmacology of drugs used in the treatment of migraine headaches.
- Apply the nursing process for the patient taking CNS stimulants.
- Apply the nursing process for the patient taking doxapram (Dopram).

dependence, p. 284
migraine headaches, p. 285
narcolepsy, p. 285
neurotransmitters, p. 285
tolerance, p. 284

Numerous drugs can stimulate the **central nervous system (CNS),** which involves the brain and spinal cord that regulates body functions. Medically approved use of CNS stimulants is limited to the treatment of attention deficit/hyperactivity disorder (ADHD) in children, narcolepsy, and the reversal of respiratory distress. The major group of CNS stimulants includes amphetamines and caffeine, which stimulate the cerebral cortex of the brain; analeptics and caffeine, which act on the brainstem and medulla to stimulate respiration; and anorexiants such as diethylpropion, which are thought to suppress appetite by stimulating the satiety center in the hypothalamic and limbic areas of the brain. Amphetamines and related anorexiants are greatly abused. Long-term use of amphetamines can produce psychological **dependence** or **tolerance**, a condition in which larger and larger doses of a drug are needed to reproduce the initial response. These medications are recommended for short-term use only (up to 12 weeks). Gradually increasing a drug dose and then abruptly stopping the drug may result in depression and withdrawal symptoms.

Drugs used to treat migraine and cluster headaches include analgesics, ergot alkaloids, and selective serotonin$_1$ receptor agonists (triptans). **Migraine headaches** generally cause severe throbbing pain. They are often preceded by an aura (visual, smells, tingling, vertigo warning). The cause is not definitive but is thought to be due to changes in the brainstem, which activates the trigeminal nerve. Low serotonin levels may also be involved by triggering the trigeminal system to release neuropeptides, which cause pain. Triggering factors for migraines include certain foods (beer, red wine, aged cheese, chocolate, caffeine, monosodium glutamate), skipping meals, intense physical exertion, female hormonal changes, bright lights, stress, weather changes, and certain medications (oral contraceptives, vasodilators). The cause of **cluster headaches** is unknown, but they are generally considered to be caused by the hypothalamus activating the trigeminal nerve. These headaches recur 1 to 3 times per day in a period lasting from approximately 2 weeks to 3 months. Cluster headaches do not typically have triggers, but once a cluster headache begins, alcohol, nicotine, and nitroglycerin immediately lead to a severe headache.

PATHOPHYSIOLOGY

Attention deficit/hyperactivity disorder (ADHD) might be caused by a dysregulation of the transmitters serotonin, norepinephrine, and dopamine. ADHD occurs primarily in children, usually before the age of 7 years, and may continue through the teenage years. In some cases, it may not be identified until early adulthood. The incidence of ADHD is three to seven times more common in boys than in girls. Characteristic behaviors of the various types of ADHD include inattentiveness, inability to concentrate, restlessness (fidgety), hyperactivity (excessive and purposeless activity), inability to complete tasks, and impulsivity.

The child with ADHD may display poor coordination, and there may be abnormal electroencephalographic (EEG) findings. Intelligence is usually not affected, but learning disabilities are often present. This disorder has also been called *minimal brain dysfunction, hyperactivity in children, hyperkinesis,* and *hyperkinetic syndrome with learning disorder.* Some professionals state that ADHD is often incorrectly diagnosed, resulting in many children receiving unnecessary treatment for months or years.

Narcolepsy is characterized by falling asleep during normal waking activities such as driving a car or talking with someone. Sleep paralysis, the condition of muscle paralysis that is normal during sleep, usually accompanies narcolepsy and affects the voluntary muscles. The narcoleptic is unable to move and may collapse.

AMPHETAMINES

Amphetamines stimulate the release of **neurotransmitters**—norepinephrine and dopamine—from the brain and sympathetic nervous system (peripheral nerve terminals). Amphetamines ordinarily cause euphoria and alertness, but they can also cause sleeplessness, restlessness, tremors, and irritability. Cardiovascular problems such as increased heart rate, palpitations, cardiac dysrhythmias, and increased blood pressure can result from continuous use of amphetamines.

The half-life of amphetamines varies from 4 to 30 hours. Amphetamines are prescribed for narcolepsy and in some cases for ADHD, when amphetamine-like drugs are ineffective. Amphetamine (Adderall) has been effective for controlling ADHD. Dextroamphetamine (Dexedrine) and methamphetamine (Desoxyn) may also be prescribed for some ADHD patients.

Side Effects and Adverse Reactions

Amphetamines can cause adverse effects in the central nervous system and the cardiovascular, gastrointestinal (GI), and endocrine systems. Side effects and adverse reactions include restlessness, insomnia, tachycardia, hypertension, heart palpitations, dry mouth, anorexia, weight loss, diarrhea, constipation, and impotence.

Amphetamine-Like Drugs for ADHD and Narcolepsy

Methylphenidate (Ritalin) and dexmethylphenidate (Focalin), classed as amphetamine-like drugs, are given to increase a child's attention span and cognitive performance (e.g., memory, reading) and to decrease impulsiveness, hyperactivity, and restlessness. Methylphenidate is also used to treat narcolepsy. There may be potential abuse of methylphenidate; thus it is classified as a controlled-substance schedule (CSS) II drug. Prototype Drug Chart 20-1 illustrates the pharmacokinetics, pharmacodynamics, and therapeutic effects of methylphenidate in the treatment of ADHD and narcolepsy. Amphetamine and amphetamine-like drugs should not be taken in the evening or before bedtime, because insomnia may result.

Modafinil (Provigil) is another drug prescribed for narcolepsy. It increases the amount of time patients with narcolepsy feel awake. Its mechanism of action is not fully known.

Methylphenidate is the most frequently prescribed drug used to treat ADHD. Table 20-1 lists the amphetamines and amphetamine-like drugs and their dosages, uses, and considerations.

Pharmacokinetics Methylphenidate is well absorbed from the GI mucosa. Methylphenidate is usually administered to children twice a day before breakfast and lunch. Because food affects its absorption rate, this drug should be given 30 to 45 minutes before meals. Methylphenidate should be given 6 hours or more before sleep, because it may cause insomnia. Transdermal patches may be worn for 9 hours. This drug is excreted in the urine; 40% of methylphenidate is excreted unchanged.

Pharmacodynamics Methylphenidate helps to correct ADHD by decreasing hyperactivity and improving attention span. This drug may also be prescribed for treating narcolepsy. Amphetamine-like drugs are considered more effective in treating ADHD than amphetamines, except for Adderall. Amphetamines are generally avoided because they have a higher potential for abuse, habituation, and tolerance. Sympathomimetics (e.g., pseudoephedrine) and psychostimulants (e.g., caffeine) taken concurrently with methylphenidate increase stimulatory effects of irritability, nervousness, tremors, and insomnia. Concurrent MAO inhibitors may cause hypertensive crisis. Methylphenidate potentiates the action of CNS stimulants, such as caffeine, and inhibits the metabolism

PROTOTYPE DRUG CHART 20-1

Methylphenidate

Drug Class

Amphetamine-like drug: CNS stimulant

Trade Names: Ritalin, Ritalin SR, Concerta, Daytrana transdermal patch, Quillivant XR

CSS II

Pregnancy Category: C

Dosage

Attention deficit/hyperactivity disorder (ADHD):

C >6 y: PO: 5-10 mg before breakfast and lunch; if necessary, increase dosage weekly by 5-10 mg; *max:* 60 mg/d

A: PO: 20-30 mg/d in divided doses before breakfast and lunch; *max:* 60 mg/d

A: PO: Sustained-release: 18-36 mg once daily; *max:* 72 mg/d

C: PO: Sustained-release: 18 mg/d; *max:* 2 mg/kg/d

Narcolepsy:

A: PO: 10-60 mg/d, in 2-3 divided doses 30 min before meals

Contraindications

Hyperthyroidism, anxiety, history of seizures, coronary artery disease, hypertension, Tourette's syndrome, glaucoma, psychosis, mental depression

Caution: Not to be used in children <6 y, depression, substance abuse, pregnancy

Drug-Lab-Food Interactions

Drug: May increase stimulatory effects of sympathomimetics and psychostimulants; may reduce effect of antihypertensives

Increases effects of oral anticoagulants, barbiturates, anticonvulsants, tricyclic antidepressants; increases hypertensive crisis with MAOIs

Food: Caffeine may increase effects

Pharmacokinetics

Absorption: Well absorbed from GI tract

Distribution: PB: 10%-33%

Metabolism: $t\frac{1}{2}$: 1.3-7.7 h

Excretion: 40% excreted unchanged in urine

Pharmacodynamics

PO: Onset: 0.5-1 h

Peak: 2 h

Sustained-release: 5 h; transdermal: 8 h

Duration: 3-6 h; Sustained-release: 8 h

Sustained-release: 4-8 h

Therapeutic Effects/Uses

To correct hyperactivity caused by ADHD, increase attention span, and control narcolepsy

Mode of Action: Research suggests modulation of serotonergic pathways by affecting changes in dopamine transport

Side Effects

Anorexia, vomiting, diarrhea, insomnia, dizziness, nervousness, restlessness, irritability, tremors, euphoria, blurred vision, headache, increased hyperactivity, abdominal pain, anemia, upper respiratory infection

Adverse Reactions

Tachycardia, hypertension, growth suppression, palpitations, seizures, transient weight loss in children; life-threatening: Exfoliative dermatitis, stroke, thrombocytopenia, hepatotoxicity

A, Adult; *ADHD,* attention deficit/hyperactivity disorder; *C,* child; *CD,* controlled dose; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *GI,* gastrointestinal; *h,* hour; *MAOI,* monoamine oxidase inhibitor; *min,* minute; *PB,* protein-binding; *PO,* by mouth; $t\frac{1}{2}$, half life; *UK,* unknown; *y,* year.

of some barbiturates, such as phenobarbital, leading to increased blood levels and potential toxicity.

Nursing Process

Patient-Centered Collaborative Care

Central Nervous System Stimulant: Methylphenidate HCl (Ritalin)

Assessment

- Determine whether patient has a history of heart disease, hypertension, hyperthyroidism, parkinsonism, or glaucoma; in such cases, the drug is usually contraindicated.
- Assess vital signs to be used for future comparisons. Closely monitor patients with cardiac disease, because the drug may reverse effects of antihypertensives.
- Assess patient's mental status (e.g., mood, affect, aggressiveness).
- Evaluate height, weight, and growth of children.
- Assess complete blood count (CBC), differential white blood cells (WBCs), and platelets before and during therapy.

Nursing Diagnoses

- Risk-prone health behavior (e.g., impulsiveness, short attention span, distractibility) that interferes with peer relationships, learning, and discipline related to hyperactivity adverse effect
- Interrupted family processes related to dysfunctional behavior
- Risk for delayed development related to treatment regimen
- Deficient knowledge related to inexperience with Ritalin drug regimen

TABLE 20-1 AMPHETAMINES AND AMPHETAMINE-LIKE DRUGS

GENERIC (BRAND NAME)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Amphetamines		
amphetamine sulfate (Adderall, Adderall XR) CSS II	Narcolepsy: A: PO: 5-60 mg/d in divided doses; *max:* 60 mg/d C: 6-12 y: PO: 5 mg q.d. or b.i.d., increase 5 mg/d weekly until desired response ADHD: C: >12 y: 5 mg b.i.d., increase 10 mg/d weekly until desired response C: 6-12 y: PO: 2.5 mg/d, increase 5 mg/d weekly until desired response; *max:* 40 mg/d	For narcolepsy, ADHD. Dosage should be minimal to control symptoms in ADHD. CNS and cardiac toxicity may occur. Pregnancy category: C; PB: UK; t½: 10 h
dextroamphetamine sulfate (Dexedrine) CSS II	ADHD: C: 3-5 y: PO: 2.5 mg/d or b.i.d. C: 6-12 y: PO: 5 mg/d or b.i.d., *max:* 40 mg/d	Uses similar to amphetamines. Has been used for weight loss and narcolepsy. May cause psychosis, aggression, and cardiac events. May cause sudden death in patients with structural cardiac abnormalities. Pregnancy category: C; PB: UK; t½: 10-12 h
lisdexamfetamine dimesylate (Vyvanse) CSS II	ADHD: A/C: >12 y: PO: 30 mg/d in morning, may increase 10-20 mg/d weekly, *max:* 70 mg/d	For ADHD. May cause anorexia, insomnia, headache, and irritability. May cause psychosis, aggression, and cardiac events. May cause sudden death in patients with structural cardiac abnormalities. Pregnancy category: C; PB: UK; t½: 10-12 h
Amphetamine-Like Drugs		
methylphenidate HCl (Ritalin) CSS II	See Prototype Drug Chart 20-1.	
modafinil (Provigil) CSS IV	A: PO: 200 mg/d in the morning Older adults: PO: 100 mg/d in the morning	For narcolepsy. Does not disrupt nighttime sleep. Common side effects include headache, nausea, diarrhea, and nervousness. Pregnancy category: C; PB: 60%; t½: 15 h
dexmethylphenidate (Focalin)	Immediate-release A and C: >6 y: PO: 2.5 mg b.i.d.; increase 2.5-5 mg/d at weekly intervals; *max:* 20 mg/d Extended-release: A: PO: 10 mg/d, may increase 10 mg/wk; *max:* 40 mg/d C: >6: PO: 5 mg/d, may increase 5 mg/wk; *max:* 30 mg/d	For ADHD. May cause psychosis, aggression, and cardiac events. May cause sudden death in patients with structural cardiac abnormalities. Pregnancy category: C; PB: UK; t½: 2.2 h
armodafinil (Nuvigil)	A and C: >16 y: PO: 150-250 mg q.d. in morning	For narcolepsy. Pregnancy category: C; PB: 60%; t½: 15 h

A, Adult; *ADHD,* attention deficit/hyperactivity disorder; *C,* child; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *h,* hour; *PB,* protein binding; *PO,* by mouth; *t½,* half life; *UK,* unknown; *y,* year; *>,* greater than.

Planning

- Patient's hyperactivity will be decreased.
- Patient will increase attention span.
- Patient's blood pressure and heart rate will be within normal limits.
- Patient will behave in a calm manner.

Nursing Interventions

- Monitor vital signs. Report irregularities.
- Evaluate height, weight, and growth of children.
- Observe patient for withdrawal symptoms (e.g., nausea, vomiting, weakness, headache).
- Monitor patient for side effects (e.g., insomnia, restlessness, nervousness, tremors, irritability, tachycardia, elevated blood pressure). Report findings.

Patient Teaching

General

- Teach patient to take drug before meals.
- Advise patient to avoid alcohol consumption.
- Encourage use of sugarless gum to relieve dry mouth.
- Teach patient to monitor weight twice a week and report weight loss.
- Advise patient to avoid driving and using hazardous equipment when experiencing tremors, nervousness, or increased heart rate.
- Teach patient not to abruptly discontinue the drug; dose must be tapered off to avoid withdrawal symptoms. Consult health care provider before modifying dose.
- Encourage patient to read labels on over-the-counter (OTC) products, because many contain caffeine. A high plasma caffeine level could be fatal.

- Teach nursing mothers to avoid taking all CNS stimulants (e.g., caffeine). These drugs are excreted in breast milk and can cause hyperactivity or restlessness in infants.
- Direct family to seek counseling for children with attention deficit/hyperactivity disorder. Drug therapy alone is not an appropriate therapy program. Notify school nurse of drug therapy regimen.
- Explain to patient and family that long-term use may lead to drug abuse.

Diet

- Advise patient to avoid foods that contain caffeine.
- Encourage parents to provide children with a nutritious breakfast because the drug may have anorexic effects.

Side Effects

- Teach patient about drug side effects and the need to report tachycardia and palpitations. Monitor children for onset of Tourette's syndrome.

Cultural Considerations

- Decrease language barriers by decoding the jargon of the health care environment for those who have language difficulties or are not in the health care field.

Evaluation

- Evaluate effectiveness of drug therapy, level of hyperactivity, and presence of adverse effects.
- Monitor weight, sleep patterns, and mental status.
- Evaluate patient's knowledge of Ritalin therapy.

ANOREXIANTS, LIPASE INHIBITORS, ANALEPTICS, AND RESPIRATORY STIMULANTS

Anorexiants

Amphetamines were once freely prescribed as **anorexiants** (appetite suppressants) for short-term use (4 to 12 weeks), but because of tolerance, psychological dependence, and abuse, they are no longer recommended for use as appetite suppressants. The U.S. Food and Drug Administration (FDA) has ordered the removal of phenylpropanolamine from OTC weight-loss drugs and cold remedies. There is increased risk of hemorrhagic stroke in young women who take drugs containing phenylpropanolamine and a 16-times greater risk in women who take the drugs as appetite suppressants. (This drug has not been associated with an increased risk of stroke in men.) It has been suggested that phenylpropanolamine might also cause renal failure, psychosis, hypertension, and cardiac dysrhythmias. Topical use of the drug has not been associated with systemic effects. Most of the anorexiants used to suppress appetite (Table 20-2) do not have the serious side effects associated with amphetamines. For weight-loss attempts, emphasis should be placed on nutritious diet, exercise, and behavior modification. Reliance on appetite suppressants should be discouraged. Individuals who take anorexiants should be under the care of a health care provider.

Side Effects and Adverse Reactions

Children younger than 12 years should not be given anorexiants, and self-medication with anorexiants should be discouraged. Long-term use of these drugs frequently results in such severe side effects as nervousness, restlessness, irritability, insomnia, heart palpitations, and hypertension.

Lipase Inhibitors

Lipase inhibitors have replaced anorexiants as the drug of choice for weight loss. They decrease GI absorption of dietary fats. The fats are excreted in feces, leading to weight loss. Side effects from lipase inhibitors include oily spotting, fecal urgency and incontinence, steatorrhea, flatus with discharge, headache, nausea, vomiting, and abdominal cramping. Hypoglycemia may occur in diabetic patients.

Analeptics

Analeptics, which are CNS stimulants, mostly affect the brainstem and spinal cord but also affect the cerebral cortex. The primary use of an analeptic is to stimulate respiration. One subgroup of analeptics is the xanthines (methylxanthines), of which caffeine and theophylline are the main drugs. Depending on the dose, caffeine stimulates the CNS, and large doses stimulate respiration. Newborns with respiratory distress might be given caffeine to increase respiration. Theophylline is used mostly to relax the bronchioles; however, it has also been used to increase respiration in newborns. Refer to Chapter 41 for further discussion of theophylline. Table 20-2 lists the analeptics and their dosages, uses, and considerations.

Side Effects and Adverse Reactions

Side effects from caffeine are similar to those from anorexiants: nervousness, restlessness, tremors, twitching, palpitations, and insomnia. Other side effects include diuresis (increased urination), GI irritation (e.g., nausea, diarrhea), and, rarely, tinnitus (ringing in the ear). More than 300 mg of caffeine affects the CNS and heart (i.e., dysrhythmias, convulsions). High doses of caffeine in coffee, chocolate, and cold-relief medications can cause psychological dependence. The half-life of caffeine is approximately 5 hours; however, the half-life is prolonged in patients with liver disease and in patients who are taking oral contraceptives or are pregnant. Caffeine is contraindicated during pregnancy, because its effect on the fetus is unknown.

TABLE 20-2 ANOREXIANTS AND ANALEPTICS

DRUG	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Anorexiants		
benzphetamine HCl (Didrex) CSS III	A: PO: 25-50 mg daily to t.i.d; *max:* 150 mg/d	Short-term (8-12 wk) treatment for weight loss. Similar to amphetamines. Potential for abuse. Avoid during pregnancy. Pregnancy category: X; PB: UK; $t_{1/2}$: 6-10 h
diethylpropion HCl (Tenuate) CSS IV	A: PO: 25 mg t.i.d. 30-60 min a.c. Sustained-release: 75 mg/d; *max:* 75 mg/d	For appetite suppression by stimulating the appetite control center in the hypothalamus. For short-term use. Pregnancy category: B; PB: UK; $t_{1/2}$: 4-8 h
phentermine HCl (Suprenza) CSS IV	A/Adol: >16 y: PO: 15-37.5 mg/d in the morning	For short-term appetite suppression. Pregnancy category: X; PB: UK; $t_{1/2}$: 19-24 h
phentermine-topiramate (Qsymia)	Extended-release: A: PO: 3.75/23 mg phentermine-topiramate q.d. for 14 d in the morning, then 7.5/46 mg/d; *max:* 15/92 mg	For short-term weight management when patient has at least one comorbid condition (hypertension, dyslipidemia, type 2 diabetes). May increase suicidal risk. Evaluate weight loss in 12 weeks. Pregnancy category: X; PB: 15%-41%; $t_{1/2}$: 20-65 h
phendimetrazine (Bontril)	A: PO: 17.5-35 mg b.i.d. or t.i.d. 1 h a.c. Extended-release: A: PO: 105 mg/d 30-60 min a.c.	For short-term appetite suppression. Pregnancy category: X; PB: UK; $t_{1/2}$: 2-10 h
Serotonin 2C Receptor Agonist		
lorcaserin (Belviq)	A: PO: 10 mg q12h	For short-term weight management when patient has at least one comorbid condition (hypertension, dyslipidemia, type 2 diabetes). May increase suicidal risk. Discontinue if 5% weight loss not achieved in 12 weeks. Pregnancy category: X; PB: 70%; $t_{1/2}$: 11 h
Analeptics		
Methylxanthines		
caffeine citrate (Cafcit, NoDoz)	Neonatal apnea: Infant: PO/IV: 20-25 mg/kg loading dose, then after 24 hr, 5-10 mg/kg/d	Used as a CNS and respiratory stimulant. Used for newborns with apnea to stimulate respiration; increases heart rate and blood pressure. Given by NGT or IV. Pregnancy category: C; PB: 36%; $t_{1/2}$: A: 3-7 h
OTC drugs: caffeine (NoDoz, Vivarin), coffee	A: 100-200 mg q3-4h PRN	Restores mental alertness. Brewed coffee contains 60-250 mg caffeine per cup. Black tea brewed 4 min has 40-100 mg caffeine.
theophylline	Infants: PO/IV: 0.5 mg/kg	Used for newborns with apnea to stimulate respiration. Given by NGT or PO. Pregnancy category: C; PB: 40%; $t_{1/2}$: A: 6.5-10.5 h, neonate: 6.5-10.5 h
Respiratory Stimulants		
doxapram HCl (Dopram)	A: IV: 0.5-1 mg/kg, may repeat to total of 2 mg/kg; infusion: 5 mg/min, then reduce to 1-3 mg/min; *max:* 4 mg/kg	Used for respiratory depression. Can increase blood pressure. Pregnancy category: B; PB: UK; $t_{1/2}$: A: 2.5-4 h, neonate: 7-10 h

Adol, Adolescent; *A,* adult; *a.c.,* before meals; *C,* child; *CSS,* Controlled Substances Schedule; *d,* day; *FDA,* U.S. Food and Drug Administration; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *min,* minute; *NGT,* nasogastric tube; *OTC,* over the counter; *PB,* protein binding; *PO,* by mouth; *subQ,* subcutaneous; $t_{1/2}$, half-life; *t.i.d.,* three times a day; *UK,* unknown.

Respiratory Stimulants

Doxapram (Dopram), a CNS and respiratory stimulant, is used to treat respiratory depression caused by drug overdose, preanesthetic and postanesthetic respiratory depression, and chronic obstructive pulmonary disease (COPD). It should be used with caution for the treatment of neonatal apnea. It is administered intravenously, and its onset of action is within 20 to 40 seconds with a peak action within 2 minutes. Side effects are infrequent; however, with an overdose, hypertension, tachycardia, tremors, spasticity, and hyperactive reflexes may occur. Mechanical ventilation is more effective than doxapram for treating patients who experience respiratory depression as a result of using certain drugs.

CRITICAL THINKING CASE STUDY

MP, a 67-year-old man, wants to lose 30 pounds. He wants to take an OTC diet pill but does not want to be on a calorie-restricted diet.

1. Would you recommend a diet pill? Why or why not?
2. What do you need to assess concerning this patient's physical status before suggesting a diet pill or an exercise program?
3. What behavior modifications might you suggest related to attempted weight loss?
4. In what ways could diet modification and exercise help this patient? Explain your answer.
5. Would you suggest a commercial weight-loss program? Why or why not?

NCLEX STUDY QUESTIONS

1. When a 12-year-old child is prescribed methylphenidate, which is most important for the nurse to monitor?
   a. Temperature
   b. Respirations
   c. Intake and output
   d. Height and weight
2. Several children are admitted for diagnosis with possible attention deficit/hyperactivity disorder. Which is most important for the nurse to observe?
   a. A girl who is lethargic
   b. A girl who lacks impulsivity
   c. A boy with smooth coordination
   d. A boy with an inability to complete tasks
3. The nurse monitoring a patient for methylphenidate withdrawal should observe the patient for which condition?
   a. Tremors
   b. Insomnia
   c. Weakness
   d. Tachycardia
4. The nurse is teaching a patient to self-administer medications. The nurse knows that which drug is used to treat narcolepsy?
   a. modafinil
   b. atomoxetine
   c. lisdexamfetamine
   d. methylphenidate
5. A newborn patient is in respiratory distress. The nurse anticipates preparation for which medication to be given?
   a. modafinil
   b. armodafinil
   c. theophylline
   d. amphetamine

Answers: 1, d; 2, d; 3, c; 4, a; 5, c.

CHAPTER 21

Central Nervous System Depressants

OBJECTIVES

- Differentiate the types and stages of sleep.
- Explain several nonpharmacologic ways to induce sleep.
- Differentiate among these adverse effects: hangover, dependence, tolerance, withdrawal symptoms, and rapid eye movement (REM) rebound.
- Discuss the uses of benzodiazepines.
- Apply the nursing process for the patient taking benzodiazepines for hypnotic use.
- Differentiate nursing interventions related to barbiturates, benzodiazepines, nonbenzodiazepines, and melatonin agonist hypnotics.
- Compare the stages of anesthesia.
- Explain the uses for topical anesthetics.
- Differentiate general and local anesthetics and their major side effects.

Drugs that are central nervous system (CNS) depressants cause varying degrees of depression (reduction in functional activity) within the CNS. The degree of depression depends primarily on the drug and the amount of drug taken. The broad classification of CNS depressants includes sedative-hypnotics, general anesthetics, analgesics, opioid and nonopioid analgesics, anticonvulsants, antipsychotics, and antidepressants. The last five groups of depressant drugs are presented in separate chapters. Sedative-hypnotics and general anesthetics are discussed in this chapter.

TYPES AND STAGES OF SLEEP

Sleep disorders such as **insomnia** (inability to fall or remain asleep) occur in 10% to 30% of Americans. Insomnia occurs more frequently in women and increases with age.

People spend approximately one third of their lives, or as much as 25 years, sleeping. Normal sleep is composed of two definite phases: **rapid eye movement (REM) sleep** and **nonrapid eye movement (NREM) sleep.** Both REM and NREM occur cyclically during sleep at about 90- minute intervals (Figure 21-1). The four succeedingly deeper stages of NREM sleep end with an episode of REM sleep, and the cycle begins again. If sleep is interrupted, the cycle begins again with stage 1 of NREM sleep. Individuals perform better during their waking hours if they experience all types and stages of sleep.

It is during the REM sleep phase that individuals experience most of their recallable dreams. Children have few REM sleep periods and have longer periods of stage 3 and 4 NREM sleep. Older adults experience a decrease in stages 3 and 4 NREM sleep and have frequent waking periods.

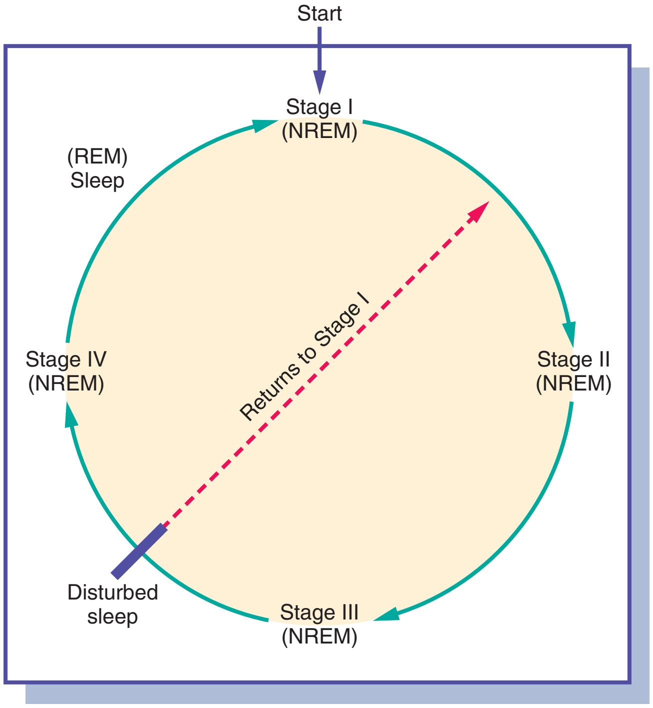

FIGURE 21–1 Types and stages of sleep. *NREM,* Nonrapid eye movement (four stages); *REM,* rapid eye movement (dreaming).

It is difficult to rouse a person during REM sleep. The period of REM sleep episodes becomes longer during the sleep process. Frequently if a person is roused from REM sleep, a vivid, bizarre dream may be recalled. If these dreams are unpleasant, they may be called *nightmares.* Sleep-walking or nightmares that occur in children take place during NREM sleep.

NONPHARMACOLOGIC METHODS

Before using sedative-hypnotics or over-the-counter (OTC) sleep aids, various nonpharmacologic methods should be used to promote sleep. Once the nurse discovers why the patient cannot sleep, the following ways to promote sleep may be suggested:

1. Arise at a specific hour in the morning.
2. Take few or no daytime naps.
3. Avoid drinks that contain caffeine and alcohol 6 hours before bedtime. Also avoid smoking nicotine 6 hours before bedtime.
4. Avoid heavy meals or strenuous exercise before bedtime.
5. Take a warm bath, listen to quiet music, or perform other soothing activities before bed.
6. Decrease exposure to loud noises.
7. Avoid drinking copious amounts of fluids before sleep.
8. Drink warm milk before bedtime.

SEDATIVE-HYPNOTICS

Sedative-hypnotics are commonly ordered for treatment of sleep disorders. The mildest form of CNS depression is **sedation,** which diminishes physical and mental responses at lower dosages of certain CNS depressants but does not affect consciousness. Sedatives are used mostly during the daytime. Increasing the drug dose can produce a **hypnotic effect**—not hypnosis but a form of "natural" sleep. Sedative-hypnotic drugs are sometimes the same drug; however, certain drugs are used more often for their hypnotic effect. With very high doses of sedative-hypnotic drugs, anesthesia may be achieved.

Sedatives were first prescribed to reduce tension and anxiety. Barbiturates were initially used for their antianxiety effect until the early 1960s, when benzodiazepines were introduced. Because of the many side effects of barbiturates and their potential for physical and mental dependency, they are now less frequently prescribed.

More than $35 million is spent each year on OTC sleep aids such as Nytol, Sominex, Sleep-Eze, and Tylenol PM. The primary ingredient in OTC sleep aids is an antihistamine such as diphenhydramine (not barbiturates or benzodiazepines).

There are short-acting hypnotics and intermediate-acting hypnotics. Short-acting hypnotics are useful in achieving sleep, because they allow the patient to awaken early in the

TABLE 21-1 COMMON SIDE EFFECTS AND ADVERSE REACTIONS OF SEDATIVE-HYPNOTICS

SIDE EFFECTS AND ADVERSE REACTIONS	EXPLANATION OF THE EFFECTS
Hangover	A hangover is residual drowsiness resulting in impaired reaction time. The intermediate- and long-acting hypnotics are frequently the cause of drug hangover. The liver biotransforms these drugs into active metabolites that persist in the body, causing drowsiness.
REM rebound	REM rebound, which results in vivid dreams and nightmares, frequently occurs after taking a hypnotic for a prolonged period then abruptly stopping. However, it may occur after taking only one hypnotic dose.
Dependence	Dependence is the result of chronic hypnotic use. Physical and psychological dependence can result. Physical dependence results in the appearance of specific withdrawal symptoms when a drug is discontinued after prolonged use. The severity of withdrawal symptoms depends on the drug and dosage. Symptoms may include muscular twitching and tremors, dizziness, orthostatic hypotension, delusions, hallucinations, delirium, and seizures. Withdrawal symptoms start within 24 hours and can last for several days.
Tolerance	Tolerance results when there is a need to increase the dosage over time to obtain the desired effect. It is mostly caused by an increase in drug metabolism by liver enzymes. The barbiturate drug category can cause tolerance after prolonged use. Tolerance is reversible when the drug is discontinued.
Excessive depression	Long-term use of a hypnotic may result in CNS depression, which is characterized by lethargy, sleepiness, lack of concentration, confusion, and psychological depression.
Respiratory depression	High doses of sedative-hypnotics can suppress the respiratory center in the medulla.
Hypersensitivity	Skin rashes and urticaria can result when taking barbiturates. Such reactions are rare.

REM, Rapid eye movement.

morning without experiencing lingering side effects. Intermediate-acting hypnotics are useful for sustaining sleep; however, after using one the patient may experience residual drowsiness, or **hangover**, in the morning. This may be undesirable if the patient is active and requires mental alertness. The ideal hypnotic promotes natural sleep without disrupting normal patterns of sleep and produces no hangover or undesirable effect. Table 21-1 lists the common side effects and adverse reactions associated with sedative-hypnotic use and abuse.

Hypnotic drug therapy should usually be short-term to prevent drug **dependence** and drug **tolerance.** Interrupting hypnotic therapy can decrease drug tolerance, but abruptly discontinuing a high dose of hypnotic taken over a long period can cause **withdrawal symptoms.** In such cases, the dose should be tapered to avoid withdrawal symptoms. As a general rule, the lowest dose should be taken to obtain sleep. Patients with severe respiratory disorders should avoid hypnotics, which could cause an increase in respiratory depression. Usually hypnotics are contraindicated during pregnancy. Ramelteon (Rozerem) is the only major sedative-hypnotic approved for long-term use. This drug may be used for treating chronic insomnia.

The category of sedative-hypnotics includes barbiturates, benzodiazepines, and nonbenzodiazepines, among others. Each category is discussed separately. Prototype drug charts are included for benzodiazepines and nonbenzodiazepines.

Barbiturates

Barbiturates were introduced as a sedative in the early 1900s. They are classified as long-acting, intermediate-acting, short-acting, and ultrashort-acting.

- The *long-acting* group includes phenobarbital and mephobarbital and is used to control seizures in epilepsy.
- The *intermediate-acting* barbiturates, such as butabarbital (Butisol), are useful as sleep sustainers for maintaining long periods of sleep. Because these drugs take approximately 1 hour for the onset of sleep, they are not prescribed for those who have trouble getting to sleep. Vital signs should be closely monitored in persons who take intermediate-acting barbiturates.
- The *short-acting* barbiturates secobarbital (Seconal) and pentobarbital (Nembutal) are used primarily for sedation preoperatively. Vital signs should be closely monitored in persons who take short-acting barbiturates.

Barbiturates should be restricted to short-term use (2 weeks or less) because of their numerous side effects, including tolerance to the drug. In the United States, barbiturates are classified in the schedule of the Controlled Substances Act as class II for short-acting, class III for intermediate-acting, and class IV for long-acting. In Canada, barbiturates are classified as schedule G. Barbiturates are listed in Table 21-2.

Pharmacokinetics Pentobarbital (Nembutal) has been available for nearly half a century and was the hypnotic of choice until the introduction of benzodiazepines in the 1960s. It has a slow absorption rate and is moderately protein-bound. The long half-life is mainly because of the formation of active metabolites resulting from liver metabolism.

Pharmacodynamics Pentobarbital and secobarbital are used primarily for short-term treatment of insomnia. Other uses include control of seizures, preoperative anxiety, and sedation induction. They have a rapid onset with a short duration of action and are considered short-acting barbiturates. The onset of action of pentobarbital is slower when administered intramuscularly (IM) than when administered orally (PO).

TABLE 21-2 SEDATIVE-HYPNOTICS: BARBITURATES AND OTHERS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Barbiturates: Short-Acting		
pentobarbital sodium (Nembutal Sodium) CSS II	Insomnia: A: PO: 100-200 mg h.s.; IM: 150-200 mg C: PO/IM: 2-6 mg/kg h.s.; *max:* 100 mg/d Preoperative: A: PO/IM: 100-200 mg in 2 divided doses Older adults: PO/IM: 100 mg in 2 divided doses C: PO/IM: 2-6 mg/kg	For sedation, sleep, or preanesthesia. May cause sleep-related behaviors and suicidal ideation. Pregnancy category: D; PB: 35%-45%; t½: 4-50 h
secobarbital sodium (Seconal Sodium) CSS II	Preoperative sedation: A: PO: 100-300 mg 1-2 h before surgery C: PO: 2-6 mg/kg 1-2 h before surgery	For preoperative sedation; may lead to sleep-related behaviors and suicidal ideation. Pregnancy category: D; PB: UK; t½: 15-40 h
Barbiturates: Intermediate-Acting		
butabarbital sodium (Butisol Sodium) CSS III	Sedative: A: PO: 15-30 mg t.i.d./q.i.d. C: PO: 2 mg/kg/dose t.i.d. Hypnotic: A: PO: 50-100 mg h.s. Preoperative sedative: A: PO: 50-100 mg, 1-1.5 h before surgery C: 2-6 mg/kg; *max:* 100 mg/d	To relieve anxiety and as short-term (less than 14 days) hypnotic for insomnia. Avoid alcohol with all barbiturates. May cause sleep-related behaviors. May cause abnormal thinking and angioedema. No longer accepted for use in older adults or debilitated adult patients for insomnia. Pregnancy category: D; PB: 50%; t½: 100 h
Barbiturates: Long-Acting		
mephobarbital (Mebaral) CSS IV	Sedative: A: PO: 32-100 mg t.i.d./q.i.d. C: PO: <5 y: 16-32 mg t.i.d./q.i.d. C: PO: >5 y: 32-64 mg t.i.d./q.i.d.	To control convulsive episodes, agitation, anxiety, suicidal ideation, and delirium tremens. Pregnancy category: D; PB: UK; t½: 11-67 h
phenobarbital (Luminal) CSS IV	A: PO: 30-200 mg/d for less than 14 days	Used more for seizure control, preoperative sedation, and anxiety. Need to monitor for respiratory depression. Pregnancy category: D; PB: 20%-45%; t½: 50-140 h

A, Adult; *b.i.d.,* two times a day; *C,* child; *CSS,* Controlled Substances Schedule; *d,* day; *h,* hour; *h.s.,* at bedtime; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *PB,* protein-binding; *p.c.,* after meals; *PO,* by mouth; *PR,* rectally; *PRN,* as needed; *q.i.d.,* four times a day; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week; <, less than; >, greater than.

SAFETY: Preventing Medication Errors

Do not confuse …

- **phenobarbital** (a long-acting barbiturate used to control seizures) with **pentobarbital** (an ultrashort-acting barbiturate used as a general anesthetic).

Many drug interactions are associated with barbiturates. Alcohol, narcotics, and other sedative-hypnotics used in combination with barbiturates may further depress the CNS. Pentobarbital increases hepatic enzyme action, causing an increased metabolism and decreased effect of drugs such as oral anticoagulants, glucocorticoids, tricyclic antidepressants, and quinidine. Pentobarbital may cause hepatotoxicity if taken with large doses of acetaminophen.

Benzodiazepines

Selected benzodiazepines (minor tranquilizer or anxiolytic) were introduced with chlordiazepoxide (Librium) in the 1960s as antianxiety agents. This drug group is ordered as sedative-hypnotics for inducing sleep. Several benzodiazepines marketed as hypnotics include flurazepam (Dalmane), alprazolam (Xanax) (Prototype Drug Chart 21-1), temazepam (Restoril), triazolam (Halcion), estazolam (ProSom), and quazepam (Doral) (Table 21-3). Increased anxiety might be the cause of insomnia for some patients, so lorazepam (Ativan) and diazepam (Valium) can be used to alleviate the anxiety. These drugs are classified as schedule IV according to the Controlled Substances Act. The benzodiazepines increase the action of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA) to the GABA receptors. Neuron excitability is reduced.

Nursing Process
Patient-Centered Collaborative Care

Sedative-Hypnotic: Benzodiazepines

Assessment

- Obtain drug history of current drugs and herbs patient is taking, especially CNS depressants, which would

PROTOTYPE DRUG CHART 21-1

Alprazolam

Drug Class

Sedative-hypnotic: benzodiazepine
Trade name: Xanax
CSS: IV
Pregnancy Category: D

Dosage

A: PO: Initially 0.25-0.5 mg h.s.; *max:* 10 mg/d

Contraindications

Respiratory depression, acute alcohol intoxication, psychotic reactions, recent respiratory depressants, hypersensitivity
Caution: Older adults, sleep apnea, renal or liver dysfunction, depression, suicidal ideation, drug abuse

Drug-Lab-Food Interactions

Drug: Decreases respiration with alcohol, CNS depressants; azole antifungals (ketoconazole), antibiotics (erythromycin), aprepitant, cimetidine, diltiazem, verapamil increase blood levels of alprazolam; rifabutin, rifampin, cortisone, phenytoin decrease blood levels; alprazolam increases digoxin and lithium levels
Food: Grapefruit increases alprazolam levels; green tea decreases alprazolam effects

Pharmacokinetics

Absorption: PO: 90% absorbed from GI tract
Distribution: PB: 80%-90%
Metabolism: $t\frac{1}{2}$: 11-16 h
Excretion: In urine as metabolites

Pharmacodynamics

PO: Onset: UK
Peak: 1-2 h (immediate-release); 9 h (extended-release); 1.5-2 h (disintegrating tablet)
Duration: UK

To Treat Anxiety and Panic Disorders

Mode of Action: CNS depression, binds receptors in limbic system and reticular formation, increases GABA to GABA receptors, shift of chloride ions leads to less excitability and stabilizes neuronal membranes

Side Effects

Lethargy, drowsiness, dizziness, headache, constipation, memory impairment, increased appetite, blurred vision, decreased libido, paradoxical reactions

Adverse Reactions

Depression, impaired coordination

A, Adult; *C,* child; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *GI,* gastrointestinal; *h,* hour; *h.s.,* at bedtime; *MAOIs,* monoamine oxidase inhibitors; *min,* minute; *PB,* protein binding; *PO,* by mouth; *$t\frac{1}{2}$,* half-life; *UK,* unknown.

potentiate respiratory depression and hypotensive effects.

- Assess baseline vital signs for future comparison.
- Determine if there is a history of insomnia or anxiety disorders.
- Assess renal function. Urine output should be 1500 mL/day. Renal impairment could prolong drug action by increasing half-life of the drug.

Nursing Diagnoses

- Sleep deprivation related to adverse effect of insomnia
- Risk for injury related to dizziness and hypotension
- Ineffective breathing pattern related to CNS depression
- Ineffective sexuality pattern related to adverse effect of erectile dysfunction

Planning

- Patient will receive adequate sleep when taking benzodiazepine.

Nursing Interventions

- Monitor vital signs, especially respirations and blood pressure.
- Use bed alarm for older adults and patients receiving a hypnotic for the first time. Confusion may occur, and injury may result.
- Observe patient for adverse reactions, especially an older adult or a debilitated patient.
- Examine patient's skin for rashes. Skin eruptions may occur in patients taking benzodiazepines.

Patient Teaching

General

- Teach patient to use nonpharmacologic ways to induce sleep (taking a warm bath, listening to quiet music, drinking warm fluids, avoiding drinks with caffeine for 6 hours before bedtime).
- Encourage patient to avoid alcohol and antidepressant, antipsychotic, and opioid drugs while taking benzodiazepines. Respiratory depression may occur when these drugs are combined.
- Warn patient that certain herbs (Herbal Alert 21-1) may interact with benzodiazepines. Herbal supplement may need to be discontinued or prescription drug dose may need to be modified.

TABLE 21-3 **SEDATIVE-HYPNOTICS: BENZODIAZEPINES AND NONBENZODIAZEPINES**

Benzodiazepines		
alprazolam (Xanax) CSS IV	See Prototype Drug Chart 21-1.	
estazolam (ProSom) CSS IV	A: PO: 1-2 mg h.s. Older adults: PO: 0.5-1 mg h.s.	For treatment of insomnia. Should not be used longer than 6 wk. Decreases frequency of nocturnal awakening. May cause sleep-driving behaviors. Pregnancy category: X; PB: 93%; t½: 10-24 h
lorazepam (Ativan) CSS IV	Insomnia: A: PO: 2-4 mg h.s. Older adults: PO: 1-2 mg h.s.	Used as a preoperative sedative and to reduce anxiety. Pregnancy category: D; PB: 91%; t½: 12-14 h
temazepam (Restoril) CSS IV	Hypnotic: A: PO: 15-30 mg h.s. Older adults: PO: 7.5 mg h.s.	To treat insomnia. Also has sedative effects. May cause sleep-related behavior. Pregnancy category: X; PB: 98%; t½: 8-15 h
triazolam (Halcion) CSS IV	Hypnotic: A: PO: 0.125-0.25 mg h.s. (*max:* 0.5 mg/d) Older adults: PO: 0.0625-0.125 mg h.s.	For management of insomnia. Should not be used longer than 7-10 d at a time to avoid tolerance. Avoid alcohol and smoking when taking triazolam. May cause sleep-related behavior. Pregnancy Category: X; PB: 90%; t½: 1.5-5.5 h
Benzodiazepine Antagonists		
flumazenil (Romazicon)	A: IV: 0.2 mg over 30 sec; may repeat with 0.3 mg in 30 sec; *max:* 3 mg total dose	Management of benzodiazepine overdose or reversal of sedative effects of benzodiazepine with general anesthesia. Pregnancy category: C; PB: 50%; t½: 54 min
Nonbenzodiazepines		
zolpidem tartrate (Ambien) CSS IV	See Prototype Drug Chart 21-2.	
eszopiclone (Lunesta) CSS IV	Insomnia: A: PO: 2-3 mg h.s. Older adults: PO: 1-2 mg h.s.	To treat insomnia. May cause sleep-related behavior, worsening of preexisting depression, and suicidal ideation. Pregnancy category: C; PB: 52%-59%; t½: 6 h
zaleplon (Sonata) CSS IV	Insomnia: A: PO: 10 mg h.s.; *max:* 20 mg h.s. Older adults: PO: 5 mg h.s.; *max:* 10 mg h.s.	For ultrashort-term treatment of insomnia. May cause sleep-related behavior. Pregnancy category: C; PB: 60%; t½: 1 h
Melatonin Agonist		
ramelteon (Rozerem)	A: PO: 8 mg with 30 minutes of bedtime	For treatment of insomnia by regulating circadian rhythm. May be used long-term for chronic insomnia. Pregnancy category: C; PB: 82%; t½: 1-2.5 h

A, Adult; *CSS,* Controlled Substances Schedule; *d,* day; *h,* hour; *h.s.,* at bedtime; *IV,* intravenous; *max,* maximum; *PB,* protein binding; *PO,* by mouth; *sec,* second; *t½,* half-life; *UK,* unknown; *wk,* week.

- Advise patient not to drive a motor vehicle or operate machinery. Caution is always encouraged.
- Encourage patient to check with health care provider about OTC sleeping aids. Drowsiness may result from taking these drugs; therefore, caution while driving is advised.

Side Effects

- Advise patient to report adverse reactions such as cognitive changes and paradoxical reactions to health care provider. Drug selection or dosage might need to be changed.
- Teach patient that benzodiazepines should be gradually withdrawn, especially if it has been taken for several weeks. Abrupt cessation may result in withdrawal symptoms (e.g., tremors, muscle twitching).

Cultural Considerations

- Use an interpreter as needed, and involve extended family in health teaching and support.
- Provide written instruction (or videos) in patient's preferred language.

Evaluation

- Assess the effectiveness of benzodiazepines.
- Evaluate respiratory status to ensure that respiratory depression has not occurred.

SAFETY: Preventing Medication Errors

Do not confuse …

- **Lorazepam** (a benzodiazepine used to reduce anxiety) with **alprazolam** (a benzodiazepine used to treat anxiety and insomnia).

Benzodiazepines (except for temazepam) can suppress stage 4 of NREM sleep, which may result in vivid dreams or nightmares and can delay REM sleep. Benzodiazepines are effective for sleep disorders for several weeks longer than

HERBAL ALERT 21-1

Sedatives

- Kava kava should not be taken in combination with CNS depressants such as barbiturates and opioids. This herb may increase the sedative effect.
- Valerian, when taken with alcohol and other CNS depressants such as barbiturates, may increase the sedative effects of the prescribed drug.

other sedative-hypnotics; to prevent *REM rebound,* however, they should not be used for longer than 3 to 4 weeks.

Triazolam (Halcion) is a short-acting hypnotic with a half-life of 2 to 5 hours. It does not produce any active metabolites. Complaints of adverse reactions to prolonged use of triazolam (e.g., loss of memory) led to its removal from the market in Great Britain, but a British advisory group is recommending that the legislative body reinstate triazolam. Its use is under review by the U.S. Food and Drug Administration (FDA). Currently, it is seldom prescribed.

Small doses of benzodiazepines are recommended for patients with renal or hepatic dysfunction. For benzodiazepine overdose, the benzodiazepine antagonist flumazenil (Romazicon) may be prescribed. Benzodiazepines prescribed as antianxiety drugs are discussed in Chapter 27.

Pharmacokinetics Benzodiazepines are well absorbed through the gastrointestinal (GI) mucosa. They are rapidly metabolized in the liver to active metabolites. Alprazolam has an intermediate half-life of 11 to 16 hours. Benzodiazepines are highly protein bound, and more free drug is available when taken with other highly protein-bound drugs, which increases the risk for adverse effects.

Pharmacodynamics Benzodiazepines are used to treat insomnia by inducing and sustaining sleep. They have a rapid onset of action and intermediate- to long-acting effects. The normal recommended dose of a benzodiazepine may be too much for the older adult, so half the dose is recommended initially to prevent overdosing.

Alcohol or opioids taken with a benzodiazepine may cause an additive depressive CNS response. Most benzodiazepines may have an adverse effect of sleep-related behaviors (eating, driving, or telephoning during sleep).

Nonbenzodiazepines

Zolpidem (Ambien) is a nonbenzodiazepine that differs in chemical structure from benzodiazepines. It is used for short-term treatment (less than 10 days) of insomnia. Its duration of action is 6 to 8 hours with a short half-life of 2 to 4.5 hours. Zolpidem is metabolized in the liver to three inactive metabolites and is excreted in bile, urine, and feces. When zolpidem is prescribed for older adults, the dose should be decreased. Table 21-3 lists the benzodiazepines and nonbenzodiazepines used as sedative-hypnotics and their dosages, uses, and considerations. Zolpidem is described in Prototype Drug Chart 21-2.

Melatonin Agonists

Ramelteon (Rozerem) is in the newest category of sedative/hypnotics, called melatonin agonists. Ramelteon is the first FDA-approved hypnotic that is not classified as a controlled substance. This drug acts by selectively targeting melatonin receptors to regulate circadian rhythm in the treatment of insomnia. Ramelteon has not been shown to decrease REM sleep. This new drug has a half life of 1 to 3 hours. Adverse effects of ramelteon include drowsiness, dizziness, fatigue, headache, nausea, and suicidal ideation. Ramelteon is also used as an antianxiety drug.

Sedatives and Hypnotics for Older Adults

Identifying the cause of insomnia in an older adult should be the first diagnostic consideration, and nonpharmacologic methods should be used before sleep medications are prescribed. Because of physiologic changes in older adults, the use of hypnotics can cause a variety of side effects.

Barbiturates increase CNS depression and confusion in older adults and should not be taken for sleep. The short- to intermediate-acting benzodiazepines such as estazolam (ProSom), temazepam (Restoril), and triazolam (Halcion) are considered safer than barbiturates. Long-acting hypnotic benzodiazepines such as flurazepam, quazepam (Doral), and diazepam (Valium) should be avoided. In many cases, older adults should be instructed to take the prescribed benzodiazepine no more than four times a week to avoid side effects and drug dependency. They can choose selected nights to take the hypnotic.

The main sleep problem experienced by older adults is frequent nighttime awakening. Reports have shown that older women experience more troublesome sleep patterns than men. Sleep disturbance may be caused by discomfort or pain. Occasionally a nonsteroidal antiinflammatory drug (NSAID) such as ibuprofen may alleviate the discomfort that prevents sleep.

Nursing Process

Patient-Centered Collaborative Care

Sedative-Hypnotic: Nonbenzodiazepines

Assessment

- Assess baseline vital signs and laboratory tests (e.g., AST, ALT, bilirubin) for future comparisons.
- Obtain drug history. Taking CNS depressants with nonbenzodiazepine hypnotics can depress respirations.
- Ascertain patient's problem with sleep disturbance.

Nursing Diagnoses

- Sleep deprivation related to anxiety
- Fatigue related to insomnia
- Risk for injury related to adverse effect sleep-related behaviors

Planning

- Patient will remain asleep for 6 to 8 hours.

PROTOTYPE DRUG CHART 21-2

Zolpidem Tartrate

Drug Class

Sedative-hypnotic: nonbenzodiazepine

Trade names: Ambien, Ambien CR (extended release), Edluar (sublingual), Intermezzo (sublingual)

CSS: IV

Pregnancy Category: C

Dosage

A: PO: 5-10 mg h.s.; *max:* 10 mg/d

Older adults: PO: 5 mg h.s.; *max:* 5-10 mg/d

Contraindications

Hypersensitivity to benzodiazepine, respiratory depression, lactation

Caution: Renal or liver dysfunction; mental depression, suicidal ideation; pregnancy; children, older adults, and debilitated individuals

Drug-Lab-Food Interactions

Drug: Decreases CNS function with alcohol, CNS depressants, anticonvulsants, and phenothiazines; increased levels with azole antifungals; decreased levels with rifampin

Food: Decreases absorption

Pharmacokinetics

Absorption: PO: well absorbed

Distribution: PB: 92%

Metabolism: t½: 2-4.5 h

Excretion: In bile, urine, and feces

Pharmacodynamics

PO: Onset: 7-27 min

Peak: 0.5-2.3 h

Duration: 6-8 h

Therapeutic Effects/Uses

To treat insomnia

Mode of Action: CNS depression, neurotransmitter inhibition

Side Effects

Drowsiness, lethargy, headache, hot flashes, hangover (residual sedation), irritability, dizziness, ataxia, visual disturbances, anxiety, mental depression, nausea and vomiting, erectile dysfunction

Adverse Reactions

Tolerance, psychological or physical dependence; sleep-related behaviors, hypotension, angioedema, dysrhythmias, suicidal ideation

A, Adult; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *h,* hour; *h.s.,* at bedtime; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life.

Nursing Interventions

- Monitor vital signs. Check for signs of respiratory depression (slow, irregular breathing patterns).
- Use bed alarm for older adults or patients receiving nonbenzodiazepines for the first time. Confusion may occur, and injury may result.
- Observe patient for side effects of nonbenzodiazepines (e.g., hangover [residual sedation], lightheadedness, dizziness, confusion).

Patient Teaching

General

- Teach patient to use nonpharmacologic ways to induce sleep (taking a warm bath, listening to music, drinking warm fluids such as milk, avoiding drinks with caffeine after dinner).
- Encourage patient to avoid alcohol, antidepressant, antipsychotic, and narcotic drugs while taking nonbenzodiazepines. Severe respiratory depression may occur when these drugs are combined.
- Advise patient to take nonbenzodiazepine before bedtime. Alprazolam takes effect within 15 to 30 minutes.
- Suggest that patient urinate before taking nonbenzodiazepine to prevent sleep disruption.
- Encourage patient to check with health care provider about OTC sleeping aids.
- Drowsiness may result from taking these drugs, so caution while driving is advised.

Side Effects

- Advise patient to report adverse reactions such as hangover to health care provider. Drug selection or dosage may need to be changed if hangover occurs.

Cultural Considerations

- Ask patient about methods family members have used to promote sleep.
- Suggest nonpharmacologic alternatives that may be effective in inducing sleep.

Evaluation

- Evaluate effectiveness of sedative-hypnotic in promoting sleep.
- Determine whether side effects such as hangover occur after several days of taking sedative-hypnotic. Another hypnotic may be prescribed if side effects persist.

ANESTHETICS

Anesthetics are classified as *general* and *local*. General anesthetics depress the CNS, alleviate pain, and cause a loss of consciousness. The first anesthetic, nitrous oxide ("laughing gas"), was used for surgery in the early 1800s. It is still an effective anesthetic and is frequently used in dental procedures and surgery.

Pathophysiology

Several theories exist regarding how inhalation anesthetics cause CNS depression and a loss of consciousness. The differing theories suggest the following about inhalation anesthetics:

1. The lipid structure of cell membranes is altered, resulting in impaired physiologic functions.
2. The inhibitory neurotransmitter gamma-aminobutyric acid (GABA) is activated to the GABA receptor that pushes chloride ions into the neurons. This greatly decreases the fire action potentials of the neurons.
3. The ascending reticular activating system is altered, and the neurons cease to transmit information (stimuli) to the brain.

Balanced Anesthesia

Balanced anesthesia is a combination of drugs that are frequently used in general anesthesia. Balanced anesthesia may include the following:

1. Intravenous anesthetics (e.g., propofol [Diprivan]) to induce and maintain anesthesia
2. Benzodiazepines (e.g., midazolam [Versed]) to reduce anxiety and provide sedation
3. Opioids (e.g., morphine, fentanyl) for analgesia
4. Neuromuscular blocking agents (e.g., pancuronium [Pavulon]) for muscle relaxation
5. Inhalation anesthetics (e.g., enflurane [Ethrane]) for induction and maintenance of general anesthesia. Also, inhalation anesthetics are helpful in producing amnesia and unconsciousness when needed.

Balanced anesthesia minimizes cardiovascular problems, decreases the amount of general anesthetic needed, reduces possible postanesthesia nausea and vomiting, minimizes the disturbance of organ function, and decreases pain. Because the patient does not receive large doses of general anesthetics, fewer adverse reactions occur. Recovery is enhanced by allowing quicker mobility.

Stages of General Anesthesia

General anesthesia proceeds through four stages (Table 21-4). The surgical procedure is usually performed during the third stage. If an anesthetic agent is given immediately before inhalation anesthesia, the third stage can occur without the early stages of anesthesia being observed. However, if the drug is given slowly, all stages of anesthesia are usually observed.

TABLE 21-4 STAGES OF ANESTHESIA

STAGE	NAME	DESCRIPTION
1	Analgesia	Begins with consciousness and ends with loss of consciousness. Speech is difficult; sensations of smell and pain are lost. Dreams and auditory and visual hallucinations may occur. This stage may be called the *induction stage.*
2	Excitement or delirium	Produces a loss of consciousness caused by depression of the cerebral cortex. Confusion, excitement, or delirium occur. Short induction time.
3	Surgical	Surgical procedure is performed during this stage. There are four phases. The surgery is usually performed in phase 2 and upper phase 3. As anesthesia deepens, respirations become more shallow and respiratory rate is increased.
4	Medullary paralysis	Toxic stage of anesthesia. Respirations are lost, and circulatory collapse occurs. Ventilatory assistance is necessary.

Assessment before Surgery

The patient's response to anesthesia may differ according to variables related to the health status of the individual. These variables include age (young and older adult), a current health disorder (e.g., renal, liver), pregnancy, history of heavy smoking, and frequent use of alcohol and drugs. These problems must be identified *before* surgery because the type and amount of anesthetic required might need adjustment.

Inhalation Anesthetics

During the third stage of anesthesia, inhalation anesthetics (i.e., gas or volatile liquids administered as gas) are used to deliver general anesthesia. Certain gases, notably nitrous oxide, are absorbed quickly, have a rapid action, and are eliminated rapidly. Cyclopropane was a popular inhalation anesthetic from 1930 to 1960, but because of its highly flammable state as ether, it is no longer used. In the late 1950s, halothane (Fluothane) was introduced as a nonflammable alternative. Other inhalation drugs used as anesthetics include methoxyflurane, enflurane (Ethrane), isoflurane (Forane), desflurane (Suprane), and sevoflurane (Ultane).

Inhalation anesthetics typically provide smooth induction. Upon discontinuing administration of halothane, isoflurane, and enflurane, recovery of consciousness usually occurs in approximately 1 hour. Recovery from desflurane and sevoflurane is within minutes. Inhalation anesthetics are usually combined with a barbiturate (e.g., midazolam), a strong analgesic (e.g., morphine), and a muscle relaxant (e.g., pancuronium) for surgical procedures.

Adverse effects from inhalation anesthetics include respiratory depression, hypotension, dysrhythmias, and hepatic dysfunction. In patients at risk, these drugs may trigger malignant hyperthermia. The newer drugs primarily cause less nausea and vomiting than the older anesthetics.

Intravenous Anesthetics

IV anesthetics may be used for general anesthesia or for the induction stage of anesthesia. For outpatient surgery of short duration, an intravenous anesthetic might be the preferred form of anesthesia. Previously thiopental sodium (Pentothal), an ultrashort-acting barbiturate, was the general anesthetic used for short-term surgery. Midazolam is more commonly used today for the rapid induction stage of anesthesia and in dental procedures. Presently droperidol (Innovar), etomidate (Amidate), and ketamine hydrochloride (Ketalar) are also used intravenously as general anesthetics. IV anesthetics have rapid onsets and short durations of action. Table 21-5 describes the inhalation and intravenous anesthetics used for general anesthesia.

Midazolam (Versed) and propofol (Diprivan) are commonly administered for the induction and maintenance of anesthesia or conscious sedation for minor surgery or procedures like mechanical ventilation or intubation. Patients are sedated and relaxed but responsive to commands.

Adverse effects from IV anesthetics include respiratory and cardiovascular depression. Propofol supports microbial

TABLE 21-5 INHALATION AND INTRAVENOUS ANESTHETICS

DRUG	INDUCTION TIME	CONSIDERATIONS
Inhalation: Volatile Liquids		
halothane (Fluothane)	Rapid	Highly potent anesthetic. Rapid recovery. Could decrease blood pressure. Has a bronchodilator effect. Contraindicated in obstetrics.
methoxyflurane (Penthrane)	Slow	Used during labor. Drug dose is usually less than other anesthetics and does not suppress uterine contraction. Could cause hypotension. Contraindicated in renal disorders.
enflurane (Ethrane)	Rapid	Can depress respiratory function; ventilatory support may be necessary. Not to be used during labor because it could suppress uterine contractions. Avoid in patients with seizure disorders.
isoflurane (Forane)	Rapid	Frequently used in inhalation therapy. Has a smooth and rapid induction of anesthesia and rapid recovery. Could cause hypotension and respiratory depression. Not to be used during labor because it suppresses uterine contractions. Has minimal cardiovascular effect.
desflurane (Suprane)	Rapid	Volatile liquid anesthetic. Rapid recovery after anesthetic administration has ceased. Could cause hypotension and respiratory depression.
sevoflurane (Ultane)	Rapid	For induction and maintenance during surgery. May be given alone or combined with nitrous oxide.
Inhalation: Gas		
nitrous oxide (laughing gas)	Very rapid	Rapid recovery. Has minimal cardiovascular effect. Should be given with oxygen. Low potency.
Intravenous (Ultrashort-Acting Barbiturates)		
methohexital sodium (Brevital sodium)	Rapid	Has short duration. Frequently used for induction and with other drugs as part of balanced anesthesia. An inhalation anesthesia usually follows.
thiamylal sodium (Surital)	Rapid	Used for induction of anesthesia and as anesthesia for electroshock therapy.
Benzodiazepines		
diazepam (Valium)	Moderate to rapid	For induction of anesthesia. No analgesic effect.
midazolam (Versed)	Rapid	For induction of anesthesia and for endoscopic procedures. IV drug can cause conscious sedation. Avoid if cardiopulmonary disorder is present.
Others		
droperidol and fentanyl (Innovar)	Moderate to rapid	A neuroleptic analgesic when combined with fentanyl (potent opiate narcotic). Frequently used with a general anesthetic. Can also be used as a preanesthetic drug. Also used for diagnostic procedures. May cause hypotension and respiratory depression.
etomidate (Amidate)	Rapid	Used for short-term surgery, for induction of anesthesia, or with a general anesthetic to maintain the anesthetic state.
ketamine hydrochloride (Ketalar)	Rapid	Used for short-term surgery or induction of anesthesia. Increases salivation, blood pressure, and heart rate. May be used for diagnostic procedures. Avoid with history of psychiatric disorders.
propofol (Diprivan)	Rapid	For induction of anesthesia; may be used with general anesthesia. Short duration of action. May cause hypotension and respiratory depression. Pain can occur at injection site, so may be mixed with a local anesthetic (lidocaine) to decrease pain.
fospropofol (Lusedra)	Rapid	For induction and maintenance of anesthesia. May cause hypotension and respiratory depression.

growth and may increase the risk for bacterial infection. Discarding opened vials within 6 hours is a necessary precaution in the prevention of sepsis.

Topical Anesthetics

Use of topical anesthetic agents is limited to mucous membranes, broken or unbroken skin surfaces, and burns. Topical anesthetics come in different forms: solution, liquid spray, ointment, cream, gel, and powder. Topical anesthetics decrease the sensitivity of nerve endings in the affected area.

Local Anesthetics

Local anesthetics block pain at the site where the drug is administered, allowing consciousness to be maintained. Local anesthetics are useful in dental procedures, suturing skin lacerations, short-term (minor) surgery at a localized area, blocking nerve impulses (nerve block) below the insertion of a spinal anesthetic, and diagnostic procedures such as lumbar puncture and thoracentesis.

Most local anesthetics are divided into two groups, the esters and the amides, according to their basic structures. The amides have a very low incidence of allergic reaction.

The first local anesthetic used was cocaine hydrochloride in the late 1800s. Procaine hydrochloride (Novocain), a synthetic of cocaine, was discovered in the early 1900s. Lidocaine hydrochloride (Xylocaine) was developed in the mid-1950s to replace procaine, except in dental procedures. Lidocaine has a rapid onset and a long duration of action, is more stable in solution, and causes fewer hypersensitivity reactions than procaine. Since the introduction of lidocaine, many local anesthetics have been marketed. Table 21-6 describes the various types of local anesthetics according to short-, moderate-, and long-acting effects.

Orthopedic joint surgeries, mastectomy, cesarean section, hysterectomy, hernia repair, and cholecystectomy frequently use the postoperative pain control provided by an anesthetic pump. For example, the patient who has a bilateral hernia repair has a catheter inserted into deep fascia of the lower abdominal area. A continuous flow of bupivacaine (Marcaine), a local anesthetic, is delivered via a Y-connector to both sides at a flow rate of approximately 2 mL/h. By controlling pain with this delivery method, the patient is allowed increased mobility, reduced opioid use (which reduces associated drowsiness and nausea), and reduced hospital stay.

Spinal Anesthesia

Spinal anesthesia requires that a local anesthetic be injected in the subarachnoid space at the third or fourth lumbar space. If the local anesthetic is given too high in the spinal column, the respiratory muscles could be affected, and respiratory distress or failure could result. Headaches might result following spinal anesthesia (a "spinal"), possibly because of a decrease in cerebrospinal fluid pressure caused by a leak of fluid at the needle insertion point. Encouraging the patient to remain flat following surgery with spinal anesthesia and to take increased fluids usually decreases the likelihood of leaking spinal fluid. Hypotension also can result following spinal anesthesia due to predisposing factors including sensory block location, history of hypertension, and chronic alcohol intake.

Various sites of the spinal column can be used for a **nerve block** with a local anesthetic (Figure 21-2). A **spinal block** is the penetration of the anesthetic into the subarachnoid membrane, the second layer of the spinal cord. An **epidural block** is the placement of the local anesthetic in the outer covering of the spinal cord, or the dura mater. A **caudal block**

TABLE 21-6 LOCAL ANESTHETICS

ANESTHETICS	TYPE	USES AND CONSIDERATIONS
Short-Acting (½ to 1 Hour)		
chloroprocaine (Nesacaine)	Ester	For infiltration, caudal, and epidural anesthesia. Onset of action is 6 to 12 minutes.
procaine HCl (Novocain)	Ester	For nerve block, infiltration, epidural, and spinal anesthesia. Useful in dentistry. Caution in use for patients allergic to ester-type anesthetics
Moderate-Acting (1 to 3 Hours)		
lidocaine (Xylocaine)	Amide	For nerve block, infiltration, epidural, and spinal anesthesia. Allergic reaction is rare. Used to treat cardiac dysrhythmias (see Chapter 42).
mepivacaine HCl (Carbocaine HCl, Isocaine, Polocaine)	Amide	For nerve block, infiltration, caudal, and epidural anesthesia. May be used in dentistry.
prilocaine HCl (Citanest)	Amide	For peripheral nerve block, infiltration, caudal, and epidural anesthesia. May be used in dentistry.
Long-Acting (3 to 10 Hours)		
bupivacaine (Marcaine, Sensorcaine)	Amide	For peripheral nerve block, infiltration, caudal, and epidural anesthesia.
dibucaine HCl (Nupercainal)	Amide	For topical use (creams and ointment) to affected areas.
etidocaine (Duranest)	Amide	For peripheral nerve block, infiltration, caudal, and epidural anesthesia.
tetracaine HCl (Pontocaine)	Ester	For spinal anesthesia (high and low saddle block). Also for topical use to affected areas such as the eye to anesthetize the cornea, the nose and throat for bronchoscopy, and the skin for relief of pain and pruritus (itching).

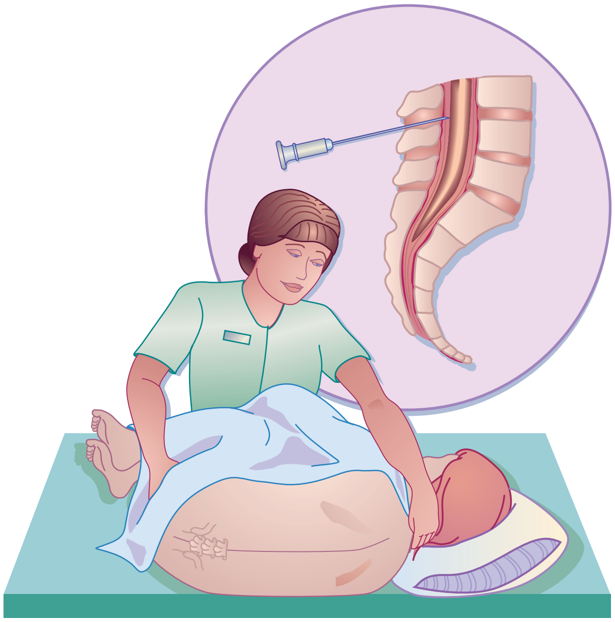

FIGURE 21–2 Positioning a patient for a spinal anesthetic.

is placed near the sacrum. A **saddle block** is given at the lower end of the spinal column to block the perineal area. Blood pressure should be monitored during administration of these types of anesthesia, because a decrease in blood pressure resulting from the drug and procedure might occur. A saddle block is frequently used for women in labor during childbirth. Further discussion of labor and delivery drugs may be found in Chapter 54.

Nursing Process

Patient-Centered Collaborative Care

Anesthetics

Assessment

- Assess baseline vital signs.
- Obtain a drug and health history, noting drugs that affect the cardiopulmonary systems.

Nursing Diagnoses

- Acute pain related to injury
- Ineffective breathing pattern related to central nervous system depression

Planning

- Patient will participate in preoperative preparation and understand postoperative care.
- Patient's vital signs will remain stable following surgery.

Nursing Interventions

- Monitor patient's postoperative state of sensorium. Report if patient remains excessively nonresponsive or confused.
- Observe preoperative and postoperative urine output. Report deficit of hourly or 8-hour urine output.
- Monitor vital signs following general and local anesthesia; hypotension and respiratory depression may result.
- Administer an analgesic or a narcotic-analgesic with caution until patient fully recovers from anesthetic. To prevent adverse reactions, dosage might need to be adjusted if patient is under the influence of anesthetic.

Patient Teaching

- Explain to patient the preoperative preparation and postoperative nursing assessment and interventions.

Cultural Considerations

- Allow adequate time for information processing for the patient whose first language is not English to avoid an inaccurate response or no response. Allow time for patients and their families to respond to questions, especially when there is a language barrier.
- Speak clearly and slowly, giving time for translation. Obtain an interpreter if necessary.

Evaluation

- Evaluate patient's response to the anesthetics. Continue to monitor patient for adverse reactions.

Nurses play an important role in patient assessment before and after general and local anesthesia is administered. Preparing the patient for surgery by explaining the preparations and completing the preoperative orders, including premedications, is necessary to enhance the safety and effectiveness of anesthesia and surgery.

KEY WEBSITES

Information on lorazepam: *www.drugs.com/lorazepam.html*

Information of eszopiclone: *www.Lunesta.com*

CRITICAL THINKING CASE STUDY

JZ, a 72-year-old woman, has difficulty staying asleep. She asks the nurse whether she should take Nytol or Sominex before bedtime.

1. Before JZ takes any sleep aid or hypnotic, what nursing assessments should be made?
2. Describe a nursing plan that may help alleviate JZ's sleep disturbance.
3. Would JZ be a candidate for taking a benzodiazepine? Explain your answer.
4. What follow-up plan should the nurse have related to JZ's sleep problem?

NCLEX STUDY QUESTIONS

1. It is important for the nurse teaching the patient regarding secobarbital (Seconal) to include which information about the drug?
   a. It is a short-acting drug that may cause one to awaken early in the morning.
   b. It is an intermediate-acting drug that frequently causes REM rebound.
   c. It is an intermediate-acting drug that frequently causes a hangover effect.
   d. It is a long-acting drug that is frequently associated with dependence.
2. A patient taking lorazepam (Ativan) asks the nurse how this drug works. The nurse should respond by stating that it is a benzodiazepine that acts by which mechanism?
   a. Depressing the central nervous system (CNS), leading to a loss of consciousness
   b. Depressing the CNS, including the motor and sensory activities
   c. Increasing the action of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA) to GABA receptors
   d. Creating an epidural block by placement of the local anesthetic in the outer covering of the spinal cord
3. A patient is taking zolpidem (Ambien) for insomnia. The nurse prepares a care plan that includes monitoring of the patient for side effects/adverse reactions of this drug. Which is a side effect of zolpidem?
   a. Insomnia
   b. Headache
   c. Laryngospasm
   d. Blood dyscrasias
4. A patient received spinal anesthesia. Which is most important for the nurse to monitor?
   a. Loss of consciousness
   b. Hangover effects and dependence
   c. Hypotension and headaches
   d. Excitement or delirium
5. A nurse is teaching a patient about zolpidem. Which is important for the nurse to include in the teaching of this drug?
   a. The maximum dose is 20 mg/d.
   b. It may lead to psychological dependence.
   c. For older adults, the dose is 15 mg at bedtime.
   d. The drug should only be used for 21 days or less.
6. A patient is taking triazolam (Halcion). Which instructions about this drug are important for the nurse to include?
   a. It may be used as a barbiturate for only 4 weeks.
   b. Use as a nonbenzodiazepine to reduce anxiety.
   c. This drug does not lead to vivid dreams or nightmares.
   d. Avoid alcohol and smoking while taking this drug.
7. A patient is to receive conscious sedation for a minor surgical procedure. Which drug administration should the nurse expect? (Select all that apply.)
   a. Propofol (Diprivan) to sustain natural sleep
   b. Lidocaine (Xylocaine) to provide local anesthesia
   c. Midazolam (Versed) to promote sedation and following of commands
   d. Ketamine (Ketalar) for rapid induction and prolonged duration of action
   e. Phenobarbital (Luminal) for short-acting duration of sleep

Answers: 1, a; 2, c; 3, b; 4, c; 5, b; 6, d; 7, a, c.

- Key Points
- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Contrast the two international classifications of seizures with characteristics of each type.
- Differentiate between the types of seizures.
- Summarize the pharmacokinetics, side effects and adverse reactions, therapeutic plasma phenytoin level, contraindications for use, and drug interactions of phenytoin (Dilantin).
- Compare the actions of hydantoins, long-acting barbiturates, succinimides, oxazolidones, benzodiazepines, iminostilbenes, and valproate.
- Apply the nursing process to anticonvulsants including patient teaching.

OUTLINE

International Classification of Seizures
Anticonvulsants
  Pharmacophysiology: Action of Anticonvulsants
  Hydantoins
  Barbiturates

Millions of people in the United States have active epilepsy, a seizure disorder. The **seizure** associated with epilepsy results from abnormal electric discharges from the cerebral neurons and is characterized by a loss or disturbance of consciousness and usually by a **convulsion** (involuntary paroxysmal muscular contractions). The **electroencephalogram (EEG)**, computed tomography (CT), and magnetic resonance imaging (MRI) are useful in diagnosing epilepsy. The EEG records abnormal electric discharges of the cerebral cortex. Of all seizure cases, 75% are considered to be primary, or **idiopathic** (of unknown cause), and the remaining are secondary to brain trauma, brain **anoxia** (absence of oxygen), infection, or cerebrovascular disorders (e.g., cerebrovascular accident, stroke). Epilepsy is a chronic, usually lifelong, disorder. The majority of persons with seizures had their first seizure before 20 years of age.

Seizures that are not associated with epilepsy could result from fever, hypoglycemic reaction, electrolyte imbalance (hyponatremia), metabolic imbalance (acidosis or alkalosis), and alcohol or drug use. When these conditions are corrected, the seizures cease. Recurrent seizures may result from birth and perinatal injuries, head trauma, congenital malformations, neoplasms (tumors), and idiopathic or unknown causes.

INTERNATIONAL CLASSIFICATION OF SEIZURES

There are various types of seizures, such as **grand mal** (tonic-clonic), **petit mal** (absence), and **psychomotor**. The international classification of seizures (Table 22-1) describes two categories of seizure: generalized and partial. A person may also have mixed (more than one type) seizures.

ANTICONVULSANTS

Drugs used for epileptic seizures are called **anticonvulsants** or antiepileptic drugs (AEDs). Anticonvulsant drugs stabilize nerve cell membranes and suppress the abnormal electric impulses in the cerebral cortex. These drugs prevent seizures but do not eliminate the cause or provide a cure. Anticonvulsants are classified as central nervous system (CNS) depressants.

With the use of anticonvulsants, seizures are controlled in approximately 70% of patients. Anticonvulsants are usually taken throughout the person's lifetime. In some cases, the health care provider might discontinue the anticonvulsant if no seizures have occurred in the past 3 to 5 years.

There are many types of anticonvulsants used to treat seizures, including the hydantoins (phenytoin), long-acting barbiturates (phenobarbital, mephobarbital, primidone), succinimides (ethosuximide), benzodiazepines (diazepam, clonazepam), carbamazepine, and valproate (valproic acid). Anticonvulsants are not indicated for all types of seizures. For example, phenytoin is effective in treating grand mal (tonic-clonic) seizures and psychomotor seizures but is not effective in treating petit mal (absence) seizures.

Pharmacophysiology: Action of Anticonvulsants

The anticonvulsant drugs work in one of three ways: (1) by suppressing sodium influx through the drug binding to the sodium channel when it is inactivated, prolonging the channel inactivation and thereby preventing neuron firing; (2) by suppressing the calcium influx, preventing the electric current generated by the calcium ions to the T-type calcium channel; or (3) by increasing the action of gamma-aminobutyric acid (GABA), which inhibits neurotransmitter throughout the brain. The drugs that suppress sodium influx are phenytoin,

TABLE 22-1 INTERNATIONAL CLASSIFICATION OF SEIZURES

CATEGORY	CHARACTERISTICS
Generalized Seizures	Convulsive and nonconvulsive; involve both cerebral hemispheres of the brain
Tonic-clonic seizure	Also called *grand mal seizure;* most common form of seizure. In the tonic phase, skeletal muscles contract or tighten in a spasm lasting 3 to 5 seconds. In the clonic phase, there is a dysrhythmic muscular contraction, or jerkiness, of legs and arms lasting 2 to 4 minutes
Tonic seizure	Sustained muscle contraction
Clonic seizure	Dysrhythmic muscle contraction
Absence seizure	Also called *petit mal seizure;* brief loss of consciousness lasting less than 10 seconds; fewer than three spike waves on the electroencephalogram (EEG) printout; usually occurs in children
Myoclonic seizure	Isolated clonic contraction or jerks lasting 3 to 10 seconds; may be limited to one limb (focal myoclonic) or involve the entire body (massive myoclonic); may be secondary to a neurologic disorder such as encephalitis or Tay-Sachs disease
Atonic seizure	Head drop; loss of posture; sudden loss of muscle tone. If lower limbs are involved, patient could collapse
Infantile spasms	Muscle spasm
Partial Seizures	Involve one hemisphere of the brain. No loss of consciousness in simple partial seizures, but there is a loss of consciousness in complex partial seizures
Simple seizure	Occurs in motor, sensory, autonomic, and psychic forms; no loss of consciousness
Motor	Formerly called the *Jacksonian seizure;* involves spontaneous movement that spreads; can develop into a generalized seizure
Sensory	Visual, auditory, or taste hallucinations
Autonomic response	Paleness, flushing, sweating, or vomiting
Psychological	Personality changes
Complex seizure	Loss of consciousness. Patient does not recall behavior immediately before, during, and immediately after seizure
Psychomotor	Complex symptoms: automatisms (repetitive behavior such as chewing or swallowing motions), behavioral changes, and motor seizures
Cognitive	Confusion or memory impairment
Affective	Bizarre behavior
Compound	May lead to generalized seizures such as tonic-clonic, tonic

fosphenytoin, carbamazepine, oxcarbazepine, valproic acid, topiramate, zonisamide, and lamotrigine. Valproic acid and ethosuximide are examples of drugs that suppress calcium influx. Examples of drug groups that enhance the action of GABA are barbiturates, benzodiazepines, and tiagabine. Gabapentin promotes GABA release.

Hydantoins

The first anticonvulsant used to treat seizures was phenytoin, a hydantoin discovered in 1938 that is still the most commonly used drug for controlling seizures. **Hydantoins** act by inhibiting sodium influx, stabilizing cell membranes, reducing repetitive neuronal firing, and limiting seizures. By increasing the electrical stimulation threshold in cardiac tissue, it also acts as an antidysrhythmic. It has a small effect on general sedation, and it is nonaddicting. However, this drug should not be used during pregnancy because it can have a **teratogenic** effect on the fetus.

SAFETY: Preventing Medication Errors

Do not confuse…

Cerebyx (hydantoin anticonvulsant) with **Celebrex** (nonsteroidal antiinflammatory drug). The names of these drugs look and sound alike but are different in their pharmacology.

Drug dosage for phenytoin and other anticonvulsants is age related. Newborns, persons with liver disease, and older adults require a lower dosage because of a decrease in metabolism resulting in more available drug. Conversely, individuals with an increased metabolic rate, such as children, may require an increased dosage. The drug dosage is adjusted according to the therapeutic plasma or serum level. Phenytoin has a narrow therapeutic range of 10 to 20 mcg/mL. The benefits of an anticonvulsant become apparent when the serum drug level is within the therapeutic range. Typically, if the drug level is below the desired range, the patient is not receiving the required drug dosage to control seizure activity. If the drug level is above the desired range, drug toxicity may result. Monitoring the therapeutic serum drug range is of utmost importance to ensure drug effectiveness. Prototype Drug Chart 22-1 lists the pharmacologic data associated with phenytoin.

Pharmacokinetics Phenytoin is slowly absorbed from the small intestine. It is a highly protein-bound (90% to 95%) drug; a decrease in serum protein or albumin can increase the free phenytoin serum level. With a small to average drug dose, the half-life of phenytoin is approximately 24 hours, but the range can be from 7 to 42 hours. Phenytoin is metabolized to inactive metabolites, and this portion is excreted in the urine.

Pharmacodynamics The pharmacodynamics of orally administered phenytoin include onset of action within 30 minutes to 2 hours, peak serum concentration in 1.5 to 6 hours, steady state of serum concentration in 7 to 10 days, and a duration of action dependent on the half-life of up to 45 hours. Oral phenytoin is most commonly ordered as a sustained-release (SR) capsule. The peak SR concentration time is 4 to 12 hours.

Intravenous (IV) infusion of phenytoin should be administered by direct injection into a large vein via a central line or peripherally inserted central catheter. The drug may be diluted in saline solution; however, dextrose solution should be avoided because of drug precipitation. The manufacturer recommends administration of phenytoin via Y-tube or three-way stopcock rather than continuous IV infusion to avoid precipitation. IV phenytoin 50 mg, or a fraction thereof, should be administered over 1 minute for adults and at a rate of 25 mg/min when the patient is older. Infusion rates of more than 50 mg/min may cause hypotension or cardiac dysrhythmias, especially with older and debilitated patients. Local irritation at the injection site may be noted, and **sloughing** (formation of dead tissue that separates from living tissue) may occur. The IV line should always be flushed with saline before and after each dose to reduce venous irritation. Intramuscular (IM) injection of phenytoin irritates tissues and may cause damage. For this reason and because of its erratic absorption rate, phenytoin is not given by the IM route.

Side Effects and Adverse Reactions

The severe side effects of hydantoins include neurologic and psychiatric effects (i.e., slurred speech, confusion, depression), thrombocytopenia (low platelet count), leukopenia (low white blood cell count), and **gingival hyperplasia** (overgrowth of the gum tissues or reddened gums that bleed easily). Patients on hydantoins for long periods might have an elevated blood sugar (hyperglycemia) that results from the drug inhibiting the release of insulin. Less severe side effects include nausea, vomiting, constipation, drowsiness, headaches, alopecia, hirsutism, and **nystagmus** (constant, involuntary, cyclical movement of the eyeball).

Drug-Drug Interactions

Drug interaction is common with hydantoins, because they are highly protein-bound. Hydantoins compete with other drugs (e.g., anticoagulants, aspirin) for plasma protein-binding sites. The hydantoins displace anticoagulants and aspirin, causing more free-drug availability and increasing their activity. Barbiturates, rifampin, and a chronic ingestion of ethanol increase hydantoin metabolism. Drugs like sulfonamides and cimetidine (Tagamet) can increase the action of hydantoins by inhibiting liver metabolism, which is necessary for drug excretion. Antacids, calcium preparations, sucralfate (Carafate), and antineoplastic drugs also decrease the absorption of hydantoins. Antipsychotics and certain herbs can lower the **seizure threshold** (level at which seizure may be induced) and increase seizure activity (Herbal Alert 22-1). The patient should be closely monitored for seizure occurrence.

Barbiturates

Phenobarbital, a long-acting barbiturate, is still prescribed to treat partial seizures, grand mal seizures, and acute episodes of **status epilepticus** seizures (rapid succession of epileptic

HERBAL ALERT 22-1

Anticonvulsants

- Evening primrose and borage may lower seizure threshold when these herbs are taken with anticonvulsants. The anticonvulsant dose may need modification.
- Ginkgo may decrease phenytoin effectiveness.

PROTOTYPE DRUG CHART 22-1

Phenytoin

Drug Class Anticonvulsant: hydantoin Trade Name: Dilantin Pregnancy Category: D	**Dosage** A: PO: 4-7 mg/kg/d IV: LD: 15-20 mg/kg/d; *max:* 30 mg/kg C: 5 mg/kg/d in 2-3 divided doses; Therapeutic serum range: 10-20 mcg/mL Toxic level: 30-50 mcg/mL
Contraindications Hypersensitivity, heart block, bradycardia, psychiatric disorders, pregnancy Caution: Hyponatremia, hypotension, hypoglycemia, suicidal ideation, myasthenia gravis, systemic lupus erythematosus	**Drug-Lab-Food Interactions** Drug: Increase effects with cimetidine, isoniazid, chloramphenicol; decrease effects with folic acid, calcium, antacids, sucralfate, vinblastine, cisplatin Decrease effects of anticoagulants, oral contraceptives, antihistamines, corticosteroids, theophylline, cyclosporin, quinidine, dopamine, rifampin Food: Decreased effects of folic acid, calcium, and vitamin D as absorption is decreased by phenytoin
Pharmacokinetics Absorption: PO: Slowly absorbed; IM: Erratic rate of absorption Distribution: PB: 90-95% Metabolism: t½: 7-42 h; average: 24 h Excretion: In urine, small amount; in bile and feces, moderate amounts	**Pharmacodynamics** PO: Onset: 0.5-2 h Peak: 1.5-6 h Duration: 6-12 h IV: Onset: Within minutes to 1 h Peak: 2 h moderate amount Duration: >12 h
Therapeutic Effects/Uses To prevent tonic-clonic (grand mal) and complex partial seizures Mode of Action: Reduces motor cortex activity by altering ion transport	
Side Effects Headache, diplopia, confusion, dizziness, sluggish, decreased coordination, ataxia, slurred speech, rash, anorexia, nausea, vomiting, hypotension (after IV administration), pink-red/brown discoloration of urine	**Adverse Reactions** Leukopenia, hepatitis, depression, gingival hyperplasia, nystagmus, hirsutism, osteoporosis Life-threatening: Aplastic anemia, thrombocytopenia, agranulocytosis, Stevens-Johnson syndrome, hypotension, ventricular fibrillation, encephalopathy, suicidal ideation

A, Adult; *C,* child; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *LD,* loading dose; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *t.i.d.,* three times a day; >, greater than; <, less than.

seizures); meningitis; toxic reactions; and eclampsia. Barbiturates reduce seizures by enhancing the activity of GABA, which is an inhibitory neurotransmitter. Possible teratogenic effects and other side effects related to phenytoin are less pronounced with phenobarbital. The therapeutic serum range of phenobarbital is 20 to 40 mcg/mL. Risks associated with the use of phenobarbital include sedation and patient tolerance to the drug. Discontinuance of phenobarbital should be gradual to avoid recurrence of seizures.

Succinimides

The succinimide drug group is used to treat absence or petit mal seizures, and it may be used in combination with other anticonvulsants to treat such seizures. Ethosuximide (Zarontin) is the succinimide of choice. Succinimides act by decreasing calcium influx through the T-type calcium channels. The therapeutic serum range of ethosuximide is 40 to 100 mcg/mL. Adverse affects include blood dyscrasias, renal and liver impairment, and systemic lupus erythematosus.

Benzodiazepines

The three benzodiazepines that have anticonvulsant effects are clonazepam, clorazepate dipotassium, and diazepam. Clonazepam is effective in controlling petit mal (absence) seizures, but tolerance may occur 6 months after drug therapy starts, and consequently clonazepam dosage must be adjusted. Clorazepate dipotassium is frequently administered in adjunctive therapy for treating partial seizures.

Diazepam is primarily prescribed for treating acute status epilepticus and must be administered IV to achieve the desired response. The drug has a short-term effect; thus other anticonvulsants such as phenytoin or phenobarbital need to be given during or immediately after administration of diazepam.

Iminostilbenes

Carbamazepine, an iminostilbene, is effective in treating refractory seizure disorders that have not responded to other anticonvulsant therapies. It is used to control grand mal and partial seizures and a combination of these seizures.

Carbamazepine is also used for psychiatric disorders (e.g., bipolar disease), trigeminal neuralgia (as an analgesic), and alcohol withdrawal. The therapeutic serum range of carbamazepine is 5 to 12 mcg/mL.

An interaction may occur when grapefruit juice is taken with carbamazepine (Tegretol), causing possible toxicity. Therefore drug concentrations must be monitored carefully.

Valproate

Valproic acid has been prescribed for petit mal, grand mal, and mixed types of seizures. The safety and efficacy of this drug has not been established for children younger than 2 years of age. Care should be taken when giving this drug to very young children and to patients with liver disorders, because hepatotoxicity is one of the possible adverse reactions. Liver enzymes should be monitored. The therapeutic serum range for a patient with seizures is 50 to 100 mcg/mL. The FDA has approved divalproex sodium (Depakote) for treatment of manic episodes associated with bipolar disorder.

Table 22-2 lists the various anticonvulsants and their dosages, uses, and considerations. Table 22-3 lists selected anticonvulsants that are frequently prescribed to treat seizure disorders.

Anticonvulsant dosages usually start low and gradually increase over a period of weeks until the serum drug level is within therapeutic range or the seizures cease. Serum anticonvulsant drug levels should be closely monitored to prevent toxicity.

Anticonvulsants and Pregnancy

During pregnancy, seizure episodes increase 25% in women with epilepsy. Hypoxia that may occur during seizures places both the pregnant woman and her fetus at risk.

Many anticonvulsant drugs have teratogenic properties that increase the risk for fetal malformations. Phenytoin and carbamazepine have been linked to fetal anomalies such as cardiac defects and cleft lip and palate. It has been reported that valproic acid is known to cause major congenital malformation in infants in 4% to 8% of pregnant women who take the drug. As expected, the highest incidence of birth defects occurs when the woman takes combinations of anticonvulsant drugs.

Anticonvulsant drugs tend to act as inhibitors of vitamin K, contributing to hemorrhage in infants shortly after birth. Frequently, pregnant women taking anticonvulsants are given an oral vitamin K supplement during the last week or 10 days of the pregnancy, or vitamin K is administered to the infant soon after birth.

Anticonvulsants also increase the loss of folate (folic acid) in pregnant women. Thus, pregnant individuals should take daily folate supplements.

Anticonvulsants and Febrile Seizures

Seizures associated with fever usually occur in children between 3 months and 5 years of age. Epilepsy develops in approximately 2.5% of children who have had one or more febrile seizures. Prophylactic anticonvulsant treatment such as phenobarbital or diazepam may be indicated for high-risk patients. Valproic acid should not be given to children younger than 2 years of age because of its possible hepatotoxic effect.

Nursing Process
Patient-Centered Collaborative Care

Anticonvulsants: Phenytoin

Assessment

- Obtain a health history including current drugs and herbs patient uses. Report and document any probable drug-drug or herb-drug interactions.
- Assess patient's knowledge regarding medication regimen.
- Check urinary output to determine whether adequate (>1500 mL/d).
- Determine laboratory values related to renal and liver function. If both BUN and creatinine levels are elevated, a renal disorder should be suspected. Elevated serum liver enzymes (alkaline phosphatase, alanine aminotransferase, gamma-glutamyl transferase, 59-nucleotidase) indicate a hepatic disorder.

Nursing Diagnoses

- Risk for injury related to decreased coordination
- Impaired oral mucous membranes related to blood dyscrasias
- Imbalanced nutrition: less than body requirements related to anorexia
- Risk for falls related to dizziness secondary to phenytoin side effect

Planning

- Patient will be free of seizures.
- Patient will adhere to anticonvulsant therapy.
- Patient's side effects from phenytoin will be minimal.

Nursing Interventions

- Monitor serum drug levels of anticonvulsant to determine therapeutic range (10 to 20 mcg/mL).
- Encourage patient's compliance to medication regimen.
- Monitor patient's CBC levels for early detection of blood dyscrasias.
- Use seizure precautions (environmental protection from sharp objects, such as table corners) for patients at risk for seizures.
- Determine whether patient is receiving adequate nutrients; phenytoin may cause anorexia, nausea, and vomiting.

TABLE 22-2 ANTICONVULSANTS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Barbiturates		
mephobarbital (Mebaral) CSS IV	A: PO: 200-600 mg/d in 2-4 divided doses; *max:* 600 mg/d for seizures C: 6-12 mg/kg/d in 2-4 divided doses	For grand mal and petit mal (absence) seizures. May be used in combination with other anticonvulsants. Also used to manage delirium tremens. May cause drowsiness, dizziness, suicidal ideation. Pregnancy category: D; PB: UK; t½: 11-67 h
phenobarbital (generic) CSS IV	Status epilepticus: A/C: IV: 15-18 mg/kg; *max:* 30 mg/kg Maintenance: A/C: PO: 1-3 mg/kg/d in 2 divided doses; Therapeutic serum range: 20-40 mcg/mL	Long-acting barbiturate. Used for grand mal (tonic-clonic) seizures, partial seizures, and to control status epilepticus. May be used in combination with phenytoin. High doses for adults may lead to coma and respiratory depression. High doses for older adults or children may cause confusion, depression, irritability. Adverse effects include suicidal ideation. Long-term use with high doses could cause physical dependence. Pregnancy category: D; PB: 20%-45%; t½: A: 50-120 h; C: 35-75 h
primidone (Mysoline)	A: PO: 125-250 mg/d; *max:* 2 g/d C: <8 y: PO: 50-125 mg/d; *max:* 25 mg/kg/d Therapeutic serum range: 5-12 mcg/mL	Barbiturate-like drug. Used to manage grand mal and psychomotor seizures. Take with food if drug causes GI distress. Pregnancy category: D; PB: 20%-45%; t½: 10-12 h
Benzodiazepines (Anxiolytics)		
clonazepam (Klonopin) CSS IV	A: PO: 1.5 mg/d; gradually increase dose q3d until seizures controlled; *max:* 20 mg/d C: PO: 0.01-0.03 mg/kg/d; *max:* 0.05 mg/kg/d	For petit mal (absence), myoclonus, and status epilepticus. May be used when petit mal seizures are refractory to succinimides or valproic acid. Pregnancy category: D; PB: 85%; t½: 25-40 h
clorazepate (Tranxene) CSS IV	A: PO: 7.5 mg t.i.d.; *max:* 90 mg/d C: >9 y: PO: 3.75-7.5 mg b.i.d.; *max:* 60 mg/d	May be used for partial seizures and as adjunctive therapy for seizures. Also treats anxiety and acute alcohol withdrawal. Pregnancy category: D; PB: 97%; t½: 48 h
diazepam (Valium) CSS IV	Status epilepticus: A: IV: 5-10 mg; repeat if needed at 10- to 15-min intervals; *max:* 30 mg C: <5 y: IV: 0.2-0.5 mg over 2-5 min; *max:* 5 mg C: >5 y: IV 1 mg/kg q2-5 min slowly; repeat if needed: *max:* 10 mg	For status epilepticus (drug of choice). Administer IV slowly to avoid respiratory depression and hypotension, and repeat q10-15min up to 30 mg PRN; then q2-4h PRN. Also treats anxiety and substance abuse withdrawal. Pregnancy category: D; PB: 98%; t½: 30-60 h
lorazepam (Ativan) CSS IV	Status epilepticus: A: IV: 4 mg over 2-5 min; *max:* 10 mg/d; may repeat in 10-15 min Anxiety: A: PO: 2-3 mg/d in 2-3 divided doses Older adult: PO: 1-2 mg/d in 2-3 divided doses; *max:* 2 mg/d for skilled nursing facility residents	To control status epilepticus. Infusion rate should not exceed 2 mg/min. Also treats anxiety and substance abuse withdrawal. Pregnancy category: D; PB: 91%; t½: 12-14 h
Hydantoins		
fosphenytoin (Cerebyx)	A: IV: LD: 10-20 mg PE/kg Maintenance: 4-6 mg PE/kg/d Status epilepticus: IV: LD: 15-20 mg PE/kg infused at 100-150 mg PE/min	For grand mal seizures, complex partial seizures, and status epilepticus. Decreases sodium and calcium ion influx in the neurons. Converts to phenytoin. Dilute in D_5W or 0.9% NaCl. Pregnancy category: D; PB: 95%-99%; t½: 8-15 min
phenytoin (Dilantin)	See Prototype Drug Chart 22-1.	
Iminostilbene		
carbamazepine (Tegretol)	A: PO: 200 mg b.i.d.; increasing doses as needed C: >6 y: PO: 10 mg/kg/d in divided doses; *max*: 35 mg/kg/d C: 6-12 y: 100 mg b.i.d.; *max:* 1g/d Therapeutic serum range: 5-12 mcg/mL	For tonic-clonic, partial, simple, and complex seizures. Used in treating seizures unresponsive to other anticonvulsants. Now approved to treat bipolar disorder. Pregnancy category: D; PB: 76%; t½: 12-17 h after repeated dosing
oxcarbazepine (Trileptal, Oxtellar XR)	A: PO: 300 mg b.i.d.; increase to 2400 mg/d C: 4-16 y: PO: 8-10 mg/kg Extended release: A: PO: Initially 600 mg qd; may increase 600 mg/d to target range of 1200-2400 mg qd	To control refractory partial seizures as monotherapy. Can be used for generalized tonic-clonic seizures and as adjunctive therapy for partial seizures. Blocks the sodium channel. Less adverse effects than carbamazepine; drug-level monitoring is usually not necessary. Pregnancy category: C; PB: 40%; t½: 2 h
Succinimides		
ethosuximide (Zarontin)	A: PO: 250 mg b.i.d.; increase dose gradually *max:* 1.5 g/d C: 3-6 y: PO: Initially 15 mg/kg/d; may increase to 40 mg/kg/d Therapeutic serum range: 40-100 mcg/mL	For petit mal (absence) and myoclonic seizures. Gastric irritation is common; may take with food. Pregnancy category: C; PB: UK; t½: A: 50-60 h, C: 25-30 h

Continued

TABLE 22-2 ANTICONVULSANTS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Valproate		
valproate, valproic acid, divalproex Na (Depakote)	A/C: PO: 10-15 mg/kg/d in divided doses; Increase 5-10 mg/kg/d weekly until seizures controlled; *max:* 60 mg/kg/d Therapeutic serum range: 50-100 mcg/mL	For psychomotor, myoclonic, absence, and tonic-clonic seizures. Also approved for bipolar disorder and migraine prophylaxis. Avoid during pregnancy. Pregnancy category: D; PB: 90%; t½: 6-16 h
Miscellaneous		
acetazolamide (Diamox)	Commonly used with other anticonvulsants: A: PO: 8-30 mg/kg/d in divided doses; *max:* 1 g/d	For grand mal, petit mal (absence), and focal seizures. Maintain adequate fluid intake to prevent renal impairment. Pregnancy category: C; PB: 90%; t½: 10-15 h
gabapentin (Neurontin)	Adjunctive therapy for partial seizures: A: PO: 300-1200 mg/d in 3 divided doses; max time between doses: 12 h; *max:* 3600 mg/d C: 3-12 y: 10-15 mg/kg/d; *max:* 50 mg/kg/d	Used as adjunctive therapy for partial seizures. Promotes GABA release. To avoid GI upset, give drug with food. High doses are limited to short-term. If drug is discontinued, gradually reduce dose to avoid occurrence of seizures. Pregnancy category: C; PB: 3%; t½: 5-7 h
lamotrigine (Lamictal)	A: PO: Initially: 50 mg/d for 2 wk; then 50 mg b.i.d. for 2 wk; increase by 100 mg/d q1-2wk up to recommended maintenance dose of 250 mg b.i.d.	For partial and tonic-clonic seizures. Also used for treatment of Lennox-Gastaut syndrome in adults and children. Blocks sodium influx. May be given with other anticonvulsants. Discontinue if rash appears as may develop life-threatening Stevens-Johnson syndrome. Pregnancy category: C; PB: 55%; t½: 25-30 h
levetiracetam (Keppra)	A: PO: 500 mg b.i.d.; may increase dose q2wk by 1000 mg/d; *max:* 3000 mg/d in divided doses	For complex partial seizures. For adjunctive and monotherapy. Unlikely to cause drug interactions. Pregnancy category: C; PB: <10%; t½: 6-8 h
tiagabine (Gabitril)	A: PO: 4 mg/d; may increase by 4-8 mg/d; *max:* 56 mg/d C: 12-18 y: PO: 4 mg/d; may increase by 4-8 mg; *max:* 32 mg/d	For partial seizures as adjunctive therapy. Increases GABA levels. Pregnancy category: C; PB: 96%; t½: 7-9 h
topiramate (Topamax)	A: PO: 50 mg/d in 2 divided doses; may increase 50 mg/d by weekly increment; *max:* 1600 mg/d C: 2-16 y: PO: Initially 25 mg/d h.s.; may increase 25 mg/d by weekly increment; *max*: 9 mg/kg/d	For partial seizures and generalized tonic-clonic seizures. Inhibits calcium channels and increases action of GABA. Older adults can take adult dose. Pregnancy category: D; PB: 15%-41%; t½: 21 h
zonisamide (Zonegran)	A/C: >16 y: PO: 100 mg/d for 2 wk; may increase 100 mg/d at 2 wk intervals; *max:* 400 mg/d	For adjunctive treatment of partial seizures. Blocks sodium and calcium channels. Does not affect serum levels of phenytoin or valproic acid. Contraindicated if sensitive to sulfonamides. Pregnancy category: C; PB: 40%; t½: 60 h
magnesium sulfate	Preeclampsia or eclampsia: A: IV: Initially 4 g over 3-4 min, follow with 1-3 g/h via infusion pump; *max:* 40 g/d Hypomagnesemic seizures: A: IV/IM: 1 to 2 g q6h for 4 doses based on blood levels, then 60 mg/kg/d	To control seizures in toxemia of pregnancy caused by eclampsia or preeclampsia. Pregnancy category: A; PB: UK; t½: UK
pregabalin (Lyrica)	Adjunctive therapy for partial seizures: A: PO: Initially 150 mg/d in 2-3 divided doses; *max:* 600 mg/d Fibromyalgia: A: PO: Initially 75 mg b.i.d.; may increase to 150 mg b.i.d. within 1 week; *max:* 450 mg/d	For partial seizures and neuralgia. Binds alpha$_2$-delta receptor sites affecting calcium channels in CNS tissues. Pregnancy category: C; PB: 0%; t½: 6 h
lacosamide (Vimpat)	A: PO: 50 mg b.i.d.; maintenance: 200-400 mg/d	For partial seizures. Side effects include blurred vision, dizziness, fatigue, suicidal ideation. Pregnancy category: C; PB: 15%; t½: 13 h
ezogabine (Potiga)	A: PO: Initially 100 mg t.i.d.; increase up to 200-400 mg t.i.d.; *max:* 1200 mg t.i.d. Older adult: PO: Initially 50 mg t.i.d.; increase up to 250 mg t.i.d.; *max:* 750 mg t.i.d.	For partial seizures. Side effects include blurred vision, nystagmus, dizziness, appetite stimulation, leukopenia, neutropenia, suicidal ideation. Pregnancy category: C; PB: 80%; t½: 7-11 h
perampanel (Fycompa)	A/C: >12 y: PO: Initially 2 mg at bedtime; increase by 2 mg/d on weekly basis to 4-8 mg qHS; *max:* 12 mg/d	For partial seizures. Common side effects include dizziness, drowsiness, headache, fatigue, and irritability. Has black box warning of life-threatening psychiatric and behavioral reactions, such as aggression, hostility, anger, and homicidal ideation. Notify health care provider if any changes in mood, behavior, or personality occur. Pregnancy category: C; PB: 95%-96%; t½: 105 h

A, Adult; *b.i.d.,* twice a day; *C,* child; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *GABA,* gamma aminobutyric acid; *GI,* gastrointestinal; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *LD,* loading dose; *max,* maximum; *min,* minute; *PB,* protein-binding; *PE,* phenytoin equivalents; *PO,* by mouth; *PRN,* as needed; *q.i.d.,* four times a day; *sol,* solution; *SR,* sustained-release; *t½,* half-life; *UK,* unknown; *y,* year; *>,* greater than; *<,* less than.

TABLE 22-3 SELECTED ANTICONVULSANTS FOR SEIZURE DISORDERS

SEIZURE DISORDER	DRUG THERAPY
Tonic-clonic (grand mal)	phenytoin carbamazepine fosphenytoin valproic acid lamotrigine primidone phenobarbital
Partial (complex-secondarily generalized)	phenytoin carbamazepine oxcarbazepine levetiracetam primidone phenobarbital tiagabine topiramate zonisamide
Absence (petit mal)	ethosuximide valproic acid lamotrigine clonazepam
Myoclonic, atonic, atypical absence	valproic acid lamotrigine clonazepam
Status epilepticus	diazepam fosphenytoin lorazepam phenytoin

- Advise female patients who are taking oral contraceptives and anticonvulsants to use an additional contraceptive method.

Patient Teaching

General

- Teach patient to shake suspension form thoroughly before use to adequately mix medication and assure accurate dosage.
- Advise patient not to drive or perform other hazardous activities when initiating anticonvulsant therapy as drowsiness may occur.
- Counsel female patients contemplating pregnancy to consult with health care provider, because phenytoin and valproic acid may have a teratogenic effect.
- Monitor serum phenytoin levels closely during pregnancy, because seizures tend to become more frequent due to increased metabolic rates.
- Warn patient to avoid alcohol and other CNS depressants, because they can cause an added depressive effect on the body.
- Explain to patient that certain herbs can interact with an anticonvulsant drug (see Herbal Alert 22-1) and dose adjustment may be required.
- Encourage patient to obtain medical alert identification card, medical alert bracelet, or tag that indicates health diagnosis and drug regimen.
- Teach patient not to abruptly stop drug therapy, but rather to withdraw the prescribed drug gradually under medical supervision to prevent seizure rebound (recurrence of seizures) and status epilepticus (continuous seizure state).

TABLE 22-4 SELECTED ANTICONVULSANTS: PHARMACOKINETICS, PHARMACODYNAMICS, AND THERAPEUTIC RANGES

PHARMACOKINETICS			PHARMACODYNAMICS				
DRUG	PROTEIN-BINDING (%)	t½	EXCRETION	PO ONSET	PEAK TIME (h)	DURATION OF ACTION (h)	THERAPEUTIC SERUM RANGE
phenytoin (Dilantin)	95	6-45 h (average 22 h)	Kidneys, bile, and GI	30 min to 2 h	1.5-3	6-12	10-20 mcg/mL
phenobarbital	20-45	2-6 d	50%-75% in urine	30-60 min	8-12	6-24	20-40 mcg/mL
ethosuximide (Zarontin)	UK	A: 50-60 h C: 25-30 h	25% in urine unchanged	UK	>4	12-60	50-150 mcg/mL
clonazepam (Klonopin)	85	25-40 h	Kidneys and feces	20-60 min	1-2	6-12	20-80 ng/mL
carbamazepine (Tegretol)	75-90	15-30 h	75% in urine, 25% in feces	Varies	4-7	6-12	5-12 mcg/mL
valproic acid (Depakene)	90	6-16 h	Kidneys	20-30 min	1-4	24	40-100 mcg/mL

A, Adult; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *min,* minute; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *>,* greater than.

- Counsel patient about the need for preventive dental checkups.
- Warn patient to take prescribed anticonvulsant, get laboratory tests as ordered, and keep follow-up visits with health care provider.
- Teach patient not to self-medicate with over-the-counter (OTC) drugs without first consulting health care provider.
- Advise patient with diabetes to monitor serum glucose levels more closely than usual because phenytoin may inhibit insulin release, causing an increase in glucose level.
- Inform patient of the existence of national, state, and local associations that provide resources, current information, and support for persons with epilepsy.

Diet

- Coach patient to take anticonvulsant at the same time every day with food or milk.

Side Effects

- Tell patient that urine may be a harmless pinkish red or reddish brown.
- Advise patient to maintain good oral hygiene and to use a soft toothbrush to prevent gum irritation and bleeding.
- Teach patient to report symptoms of sore throat, bruising, and nosebleeds, which may indicate a blood dyscrasia.
- Encourage patient to inform health care provider of adverse reactions such as gingivitis, nystagmus, slurred speech, rash, and dizziness. Stevens-Johnson syndrome begins with a rash.

Cultural Considerations

- Communicate respect for cultural beliefs concerning refusal or reluctance to take anticonvulsant medications daily for life; use an interpreter and the extended family as needed to help patient understand importance of keeping to a prescribed drug regimen.
- Use a written drug schedule in patient's preferred language to support adherence to prescribed drug regimen.
- Encourage patient's compliance with follow-up by a community nurse.
- When language barriers exist, videos and pictures showing patient's own cultural group may help strengthen compliance with health interventions.

Evaluation

- Evaluate effectiveness of drug in controlling seizures.
- Continue to monitor serum phenytoin levels to determine whether they are within desired range. High serum levels of phenytoin are frequently indicators of phenytoin toxicity.
- Monitor patient for hydantoin overdose. Initial symptoms are nystagmus and ataxia (impaired coordination). Later symptoms are hypotension, unresponsive pupils, and coma. Respiratory and circulatory support, as well as hemodialysis, are usually used in the treatment of phenytoin overdose.

Anticonvulsants and Status Epilepticus

Status epilepticus, a continuous seizure state, is considered a medical emergency. If treatment is not begun immediately, death could result. The choices of pharmacologic agents are diazepam (Valium) administered IV or lorazepam (Ativan) followed by IV administration of phenytoin (Dilantin). For continued seizures, midazolam (Versed) or propofol (Diprivan) and then high-dose barbiturates are used. These drugs should be administered slowly to avoid respiratory depression.

The pharmacologic behavior of specific anticonvulsants is summarized in Table 22-4.

CRITICAL THINKING CASE STUDY

SS, a 26-year-old woman, takes phenytoin 100 mg t.i.d. to control grand mal seizures. SS and her husband are contemplating starting a family.

1. What action should the nurse take in regard to patient family planning?

   SS complains of frequent "upset stomach" and "bleeding gums" when brushing her teeth.

2. To decrease GI distress, what can be suggested?
3. To alleviate bleeding gums, what patient teaching for SS may be included?
4. The nurse checks SS's serum phenytoin level. What are the indications of an abnormal serum level? What appropriate actions should be taken?

NCLEX STUDY QUESTIONS

1. The nurse witnesses a patient's seizure involving generalized contraction of the body followed by jerkiness of the arms and legs. The nurse reports that this is which type of seizure?
   - a. Myoclonic
   - b. Petit mal
   - c. Tonic clonic
   - d. Psychomotor
2. Phenytoin has been prescribed for a patient with seizures. The nurse should include which appropriate nursing intervention in the plan of care?
   - a. Report an abnormal phenytoin level of 18 mcg/mL.
   - b. Monitor CBC levels for early detection of blood dyscrasias.
   - c. Encourage the patient to brush teeth vigorously to prevent plaque buildup.
   - d. Teach the patient to stop the drug immediately when passing pinkish-red or reddish-brown urine.
3. When administering phenytoin, the nurse realizes more teaching is needed if the patient makes which statement?
   - a. "I must shake the oral suspension very well before pouring it in the dose cup."
   - b. "I cannot drink alcoholic beverages when taking phenytoin."
   - c. "I should take phenytoin 1 hour before meals."
   - d. "I will need to get periodic dental checkups."
4. A patient is having absence (petit mal) seizures. Which of the following does the nurse expect to be prescribed for this type of seizures? (Select all that apply.)
   - a. phenytoin (Dilantin)
   - b. phenobarbital (Luminal)
   - c. valproic acid (Depakote)
   - d. clonazepam (Klonopin)
   - e. ethosuximide (Zarontin)
5. A patient is admitted to the emergency department with status epilepticus. Which drug should the nurse most likely prepare to administer to this patient? (Select all that apply.)
   - a. diazepam (Valium)
   - b. midazolam (Versed)
   - c. gabapentin (Neurontin)
   - d. levetiracetam (Keppra)
   - e. topiramate (Topamax)
6. The nurse should monitor the patient receiving phenytoin for which adverse effect?
   - a. Psychosis
   - b. Nosebleeds
   - c. Hypertension
   - d. Gum erosion
7. The nurse is administering valproic acid (Depakote) to a patient. The nurse checks the laboratory values and finds a serum range for valproic acid of 200 mcg/ml. What should the nurse do?
   - a. Increase the daily dose to get the patient's level to a therapeutic range.
   - b. Hold the morning dose but give the other scheduled dosages for the day.
   - c. Ask the patient if he is having any adverse effects from the medication.
   - d. Hold the medication and notify the health care provider.

Answers: 1, c; 2, b; 3, c; 4, c, d, e; 5, a, b; 6, b; 7, d.

OBJECTIVES

- Summarize the pathophysiology of parkinsonism and Alzheimer's disease.
- Contrast the actions of anticholinergics, dopaminergics, dopamine agonists, MAO-B inhibitors, and COMT inhibitors in the treatment of parkinsonism.
- Compare the side effects of various antiparkinsonism drugs.
- Apply the nursing process to anticholinergics, dopaminergics, and acetylcholinesterase inhibitors.
- Differentiate the phases of Alzheimer's disease with corresponding symptoms.
- Compare the side effects/adverse effects of acetylcholinesterase inhibitors that are used to treat Alzheimer's disease.

Alzheimer's disease, p. 314
bradykinesia, p. 314
dopamine agonists, p. 315
dyskinesia, p. 321
dystonic movement, p. 317
parkinsonism, p. 314
pseudoparkinsonism, p. 315

Parkinsonism (Parkinson's disease) is a chronic neurologic disorder that affects the extrapyramidal motor tract (which controls posture, balance, and locomotion). It is considered a syndrome (combination of symptoms) because of its three major features: rigidity, **bradykinesia** (slow movement), and tremors. Rigidity (abnormally increased muscle tone) increases with movement. Postural changes caused by rigidity and bradykinesia include the chest and head thrust forward with the knees and hips flexed, a shuffling gait, and the absence of arm swing. Other characteristic symptoms are masked facies (no facial expression), involuntary tremors of the head and neck, and pill-rolling motions of the hands. The tremors may be more prevalent at rest.

Alzheimer's disease is a chronic, progressive, neurodegenerative condition with marked cognitive dysfunction. Various theories exist as to the cause of Alzheimer's disease: neuritic plaques, degeneration of the cholinergic neurons, and deficiency in acetylcholine.

PARKINSONISM

In 1817, Dr. James Parkinson described six patients as having "shaking palsy." Three symptoms were described by Parkinson: (1) involuntary tremors of the limbs, (2) rigidity of muscles, and (3) slowness of movement. In the United States, there are approximately one million persons with **parkinsonism,** and 50,000 new cases are diagnosed each year. Because parkinsonism generally affects patients 50 years of age and older, many consider the health problem to be part of the aging process caused by loss of neurons. The three cardinal symptoms are rigidity, tremors, and bradykinesia. Normally the symptoms have a gradual onset and are usually mild and unilateral in the beginning.

There are different types of parkinsonism. **Pseudoparkinsonism** frequently occurs as an adverse reaction to antipsychotic drugs, especially the phenothiazines. In addition, parkinsonism symptoms could result from poisons (e.g., carbon monoxide, manganese), arteriosclerosis, and Wilson's disease (hepatolenticular degeneration).

Nonpharmacologic Measures

Symptoms of parkinsonism can be lessened through the use of nonpharmacologic measures such as patient teaching, exercise, nutrition, and group support. Exercise can improve mobility and flexibility; the patient with parkinsonism should enroll in a therapeutic exercise program tailored to this disorder. A balanced diet with fiber and fluids helps prevent constipation and weight loss. Patients with parkinsonism and their family members should be encouraged to attend a support group to help cope with and understand this disorder.

Pathophysiology

Parkinsonism is caused by an imbalance of the neurotransmitters dopamine (DA) and acetylcholine (ACh). It is marked by degeneration of neurons of the extrapyramidal motor tract. The reason for the degeneration of neurons is unknown.

There are two neurotransmitters within neurons of the striatum of the brain: dopamine, an inhibitory neurotransmitter, and acetylcholine, an excitatory neurotransmitter. Dopamine is released from the dopaminergic neurons; acetylcholine is released from the cholinergic neurons. Dopamine normally maintains control of acetylcholine and inhibits its excitatory response. In parkinsonism, there is an unexplained degeneration of the dopaminergic neurons, and an imbalance between dopamine and acetylcholine occurs. With less dopamine production, the excitatory response of acetylcholine exceeds the inhibitory response of dopamine. An excessive amount of acetylcholine stimulates neurons that release GABA. With increased stimulation of GABA, the symptomatic movement disorders of parkinsonism occur.

By the time early symptoms of parkinsonism appear, 80% of the striatal dopamine has already been depleted. The remaining striatal neurons synthesize dopamine from levodopa and release dopamine as needed. Before the next dose of levodopa, symptoms (e.g., slow walking, loss of dexterity) return or worsen, but within 30 to 60 minutes of receiving a dose, the patient's functioning is much improved.

Drugs used to treat parkinsonism reduce the symptoms or replace the dopamine deficit. These drugs fall into five categories: (1) anticholinergics, which block cholinergic receptors; (2) dopamine replacements, which stimulate dopamine receptors; (3) **dopamine agonists,** which stimulate dopamine receptors; (4) MAO-B inhibitors, which inhibit the monoamine oxidase-B (MAO-B) enzyme that interferes with dopamine; and (5) COMT inhibitors, which inhibit the catechol *O*-methyltransferase enzyme that inactivates dopamine. Table 23-1 compares the various parkinsonism drugs.

Anticholinergics

Anticholinergic drugs reduce the rigidity and some of the tremors characteristic of parkinsonism but have minimal effect on bradykinesia. The anticholinergics are parasympatholytics that inhibit the release of acetylcholine. Anticholinergics are still used to treat drug-induced parkinsonism, or pseudoparkinsonism, a side effect of the antipsychotic drug group phenothiazines. Examples of anticholinergics used for parkinsonism include trihexyphenidyl (Artane), benztropine (Cogentin), and biperiden (Akineton).

SAFETY: Preventing Medication Errors

Do not confuse …

- **Artane** with **Altace**

Diphenhydramine (Benadryl), an antihistamine, has similar anticholinergic properties. It is sometimes used to treat mild parkinsonism and for older adults who may not be able to tolerate the dopamine agonist group of drugs.

HERBAL ALERT 23-1

Orphenadrine Citrate

Valerian and kava kava potentiate sedation.

Nursing Process

Patient-Centered Collaborative Care

Antiparkinson: Anticholinergic Agent

Assessment

- Obtain patient's health history. Report if patient has a history of glaucoma, GI dysfunction, urinary retention, angina pectoris, or myasthenia gravis. All anticholinergics are contraindicated if patient has glaucoma.

TABLE 23-1 COMPARISON OF DRUGS USED TO TREAT PARKINSON'S DISEASE

DRUG	PURPOSE
Dopaminergics	
carbidopa-levodopa	Decreases symptoms of parkinsonism. Carbidopa, a decarboxylase inhibitor, permits more levodopa to reach the striatum nerve terminals (where levodopa is converted to dopamine). With the use of carbidopa, less levodopa is needed.
Dopamine Agonists	
amantadine	First used as an antiviral drug for influenza A. Decreases symptoms of parkinsonism. Can be used for early treatment of Parkinson's disease, which could delay the necessity of levodopa. Is effective in treating drug-induced parkinsonism, and has fewer side effects than anticholinergics.
bromocriptine	A D_2-dopamine receptor agonist. Can be used for early treatment of Parkinson's disease. With increasing motor symptoms, can be given with levodopa therapy.
pramipexole (Mirapex), ropinirole HCl (Requip)	D_2- and D_3-dopamine receptor agonists. Can be used in combination with levodopa. Fewer side effects than older dopamine agonists.
MAO-B Inhibitors	
selegiline HCl (Eldepryl)	Inhibits catabolic enzymes of dopamine. Extends action of dopamine. Can be used for early treatment of Parkinson's disease. If given with levodopa, dosage of levodopa is usually decreased.
rasagiline (Azilect)	Inhibits breakdown of dopamine at synapses in the brain. Allows neurons to reabsorb more dopamine for use later.
COMT Inhibitors	
entacapone (Comtan), tolcapone (Tasmar)	Inhibits COMT enzyme, increasing concentration of levodopa. Used in combination with levodopa-carbidopa (Sinemet). With COMT inhibitors, smaller dose of levodopa is needed.
Anticholinergics; Antiparkinson	
	First group of drugs used to treat Parkinson's disease before levodopa and dopamine agonists were introduced. Useful in decreasing tremors related to Parkinson's disease. The major use of these agents currently is to treat drug-induced parkinsonism. Treatment starts with low dosages, and then dose is gradually increased. Older adults are more susceptible to the many side effects of anticholinergics. Patients with memory loss or dementia should not be on anticholinergic therapy.

COMT, Catechol *O*-methyltransferase; *MAO-B,* monoamine oxidase-B.

- Obtain a drug history. Report any probable drug-drug interaction, such as phenothiazines, tricyclic antidepressants, and antihistamines, which increase the effect of trihexyphenidyl.
- Assess baseline vital signs for future comparison. Pulse rate may increase.
- Assess patient's knowledge regarding medication regimen.
- Determine usual urinary output as a baseline for comparison. Urinary retention may occur with continuous use of anticholinergics.

Nursing Diagnoses

- Impaired physical mobility related to muscle rigidity, tremors, and bradykinesia
- Impaired urinary elimination related to urinary retention
- Knowledge deficit related to unfamiliarity with drug regimen

Planning

- Patient will have decreased involuntary symptoms caused by parkinsonism or drug-induced parkinsonism.

Nursing Interventions

- Monitor vital signs, urine output, and bowel sounds. Increased pulse rate, urinary retention, and constipation are side effects of anticholinergics.
- Observe for involuntary movements.

Patient Teaching

General

- Advise patient to avoid alcohol, cigarettes, caffeine, and aspirin to decrease gastric acidity.

Side Effects

- Encourage patient to relieve dry mouth with hard candy, ice chips, or sugarless chewing gum. Anticholinergics decrease salivation.
- Suggest that patient use sunglasses in direct sunlight because of possible photophobia.
- Advise patient to void before taking the drug to minimize urinary retention.
- Counsel patient who takes an anticholinergic for control of symptoms of parkinsonism to have routine eye examinations because patients who have glaucoma should not take anticholinergics.

Diet

- Encourage patient to ingest foods high in fiber and increase fluid intake to prevent constipation.

Cultural Considerations

- Assess personal beliefs of patient or family, and modify communications to meet cultural needs; use an interpreter and community nurse follow-up as needed.

Evaluation

- Evaluate patient's response to trihexyphenidyl or benztropine mesylate to determine whether parkinsonism symptoms are controlled.

Table 23-2 lists the anticholinergics and their dosages, uses, and considerations. Anticholinergics used to treat parkinsonism are also discussed in Chapter 19.

Dopaminergics

Carbidopa and Levodopa

The first dopaminergic drug was levodopa (L-dopa), which was introduced in 1961 but is no longer available in the United States. When introduced, levodopa was effective in diminishing symptoms of Parkinson's disease and increasing mobility, because the blood-brain barrier admits levodopa but not dopamine. The enzyme dopa decarboxylase converts levodopa to dopamine in the brain, but this enzyme is also found in the peripheral nervous system and allows 99% of levodopa to be converted to dopamine *before* it reaches the brain. Therefore only about 1% of levodopa taken is available to be converted to dopamine once it reaches the brain, and large doses are needed to achieve a pharmacologic response. These high doses could cause many side effects, including nausea, vomiting, dyskinesia, orthostatic hypotension, cardiac dysrhythmias, and psychosis.

Because of the side effects of levodopa and the fact that so much levodopa is metabolized before reaching the brain, an alternative drug, carbidopa, was developed to inhibit the enzyme dopa decarboxylase. By inhibiting the enzyme in the peripheral nervous system, more levodopa reaches the brain. The carbidopa is combined with levodopa in a ratio of 1 part carbidopa to 10 parts levodopa. Figure 23-1 illustrates the comparative action of levodopa and carbidopa-levodopa.

The advantages of combining levodopa with carbidopa are as follows:

- More dopamine reaches the basal ganglia.
- Smaller doses of levodopa are required to achieve the desired effect.

The disadvantage of the carbidopa-levodopa combination is that with more available levodopa, more side effects may be noted. Side effects may include nausea, vomiting, **dystonic movement** (involuntary abnormal movement), and psychotic behavior. The peripheral side effects of levodopa are not as prevalent; however, cardiac dysrhythmia, palpitations, and orthostatic hypotension may occur. The carbidopa-levodopa combination is usually not used to treat drug-related pseudoparkinsonism. Prototype Drug Chart 23-1 lists the pharmacologic behavior of carbidopa-levodopa.

Dopamine Agonists

Other dopaminergics called **dopamine agonists** stimulate the dopamine receptors. For example, amantadine hydrochloride (Symmetrel) is an antiviral drug that acts on the dopamine receptors. It may be taken alone or in combination with carbidopa-levodopa or an anticholinergic drug. Initially, amantadine produces improvement in symptoms of

TABLE 23-2 ANTIPARKINSON DRUGS: ANTICHOLINERGICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
benztropine mesylate (Cogentin)	Parkinsonism: A: PO/IM: Initially 0.5-1 mg/d h.s. *maint:* 6 mg/d in 2 divided doses; *max:* 8 mg/d Extrapyramidal syndrome: A: PO: 1-4 mg q.d./b.i.d.	For parkinsonism and drug-induced parkinsonism to reduce dystonia. May be taken with other antiparkinson drugs. Contraindicated in glaucoma, GI obstruction, severe ulcerative colitis, prostatic hypertrophy, myasthenia gravis. Pregnancy category: C; PB: UK; $t_{1/2}$: UK
biperiden HCl (Akineton)	Parkinsonism: A: PO: 2 mg t.i.d./q.i.d.; *max:* 16 mg/d EPS: A: PO/IM: 2 mg q.d./b.i.d.; *max:* 8 mg/d C: IM: 40 mcg/kg, may repeat q30min; *max:* 4 mg/d	For parkinsonism and drug-induced parkinsonism (EPS). With prolonged use, drug tolerance may occur. Similar contraindications as benztropine. Avoid taking drug with alcohol or CNS depressants. Dry mouth, blurred vision, drowsiness, muscle weakness, and constipation may occur. Pregnancy category: C; PB: UK; $t_{1/2}$: UK
trihexyphenidyl HCl (Artane)	Parkinsonism: A: PO: 1 mg initially, increase by 2 mg q3-5d up to 6-10 mg/d; *max:* 15 mg/d EPS: A: PO: 1 mg initially, increase to 5-15 mg/d in divided doses	For treating involuntary movement symptoms of parkinsonism and drug-induced pseudoparkinsonism. Does not treat drug-induced tardive dyskinesia. Pregnancy category: C; PB: UK; $t_{1/2}$: 5-10 h

A, Adult; *b.i.d.,* two times a day; *C,* child; *CNS,* central nervous system; *d,* day; *EPS,* extrapyramidal symptoms; *GI,* gastrointestinal; *GU,* genitourinary; *h,* hour; *h.s.,* at bedtime; *IM,* intramuscular; *IV,* intravenous; *min,* minute; *PB,* protein-binding; *p.c.,* after meals; *PO,* by mouth; *PRN,* as needed; *q.i.d.,* four times a day; $t_{1/2}$, half-life; *t.i.d.,* three times a day; *UK,* unknown.

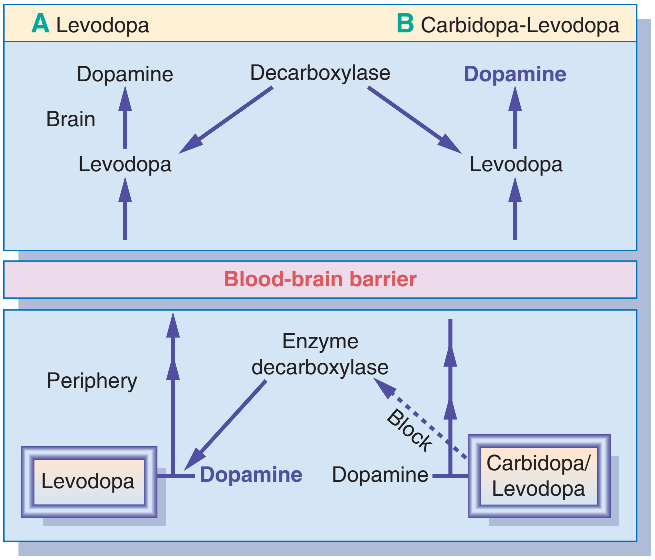

FIGURE 23–1 **A**, When levodopa is used alone, only 1% reaches the brain because 99% converts to dopamine while in the peripheral nervous system. **B**, By combining carbidopa with levodopa, carbidopa can inhibit the enzyme decarboxylase in the periphery, thereby allowing more levodopa to reach the brain.

parkinsonism in approximately two thirds of patients, but this improvement is usually not sustained, because drug tolerance develops. Amantadine can also be used to treat drug-induced parkinsonism.

Bromocriptine mesylate (Parlodel) acts directly on dopamine receptors in the central nervous system (CNS), cardiovascular system, and gastrointestinal (GI) tract. Bromocriptine is more effective than amantadine and the anticholinergics; however, it is not as effective as carbidopa-levodopa in alleviating parkinsonism symptoms. Patients who do not tolerate carbidopa-levodopa are frequently given bromocriptine.

SAFETY: Preventing Medication Errors

Do not confuse …
- **Symmetrel** with **Synthroid**
- **Parlodel** with **pindolol**
- **Mirapex** with **MiraLax**

MAO-B Inhibitors

The enzyme monoamine oxidase-B (MAO-B) causes catabolism (breakdown) of dopamine. Selegiline inhibits MAO-B, thus prolonging the action of levodopa. It may be ordered for

PROTOTYPE DRUG CHART 23-1

Carbidopa-Levodopa

Drug Class Antiparkinson: dopamine replacement Trade Name: Sinemet Pregnancy Category: C	**Dosage** A: PO: Initially 1 tablet containing 10 or 25 carbidopa/100 levodopa t.i.d./q.i.d.; maint: 25/250 mg t.i.d./q.i.d.; *max:* 8 tablets/d Extended-release: 50 mg carbidopa/200 mg levodopa b.i.d.
Contraindications Narrow-angle glaucoma; severe cardiac, renal, hepatic disease; suspicious skin lesions (activates malignant melanoma) Caution: Peptic ulcer, psychiatric disorders, seizure disorder, suicidal ideation	**Drug-Lab-Food Interactions** Drug: Increase hypertensive crisis with MAOIs Decrease levodopa effect with anticholinergics, antipsychotics Lab: May increase BUN, AST, ALT, ALP, LDH
Pharmacokinetics Absorption: PO: Well absorbed Distribution: PB: Carbidopa: 36%; levodopa: UK Metabolism: $t\frac{1}{2}$: 1-2 h Excretion: In urine as metabolites	**Pharmacodynamics** PO: Onset: 15 min; ER: onset: 4-6 h Peak: 1-3 h Duration: 5-2 h
Therapeutic Effects/Uses To treat parkinsonism; to relieve tremors and rigidity Mode of Action: Transmission of levodopa to brain cells for conversion to dopamine; carbidopa blocks the conversion of levodopa to dopamine in the intestine and peripheral tissues	
Side Effects Anorexia, nausea, vomiting, dysphagia, fatigue, dizziness, headache, dry mouth, bitter taste, twitching, blurred vision, insomnia, dark urine	**Adverse Reactions** Involuntary movements, palpitations, orthostatic hypotension, urinary retention, priapism, psychosis, severe depression with suicidal ideation, hallucinations Life-threatening: Agranulocytosis, hemolytic anemia, thrombocytopenia, cardiac dysrhythmias, neuroleptic malignant syndrome

A, Adult; *ALP,* alkaline phosphatase; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *b.i.d.,* two times a day; *BUN,* blood urea nitrogen; *h,* hour; *LDH,* lactic dehydrogenase; *maint,* maintenance; *MAOIs,* monoamine oxidase inhibitors; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t ½,* half-life; *t.i.d.,* three times a day; *UK,* unknown.

newly diagnosed patients with parkinsonism. The use of selegiline could delay carbidopa-levodopa therapy by 1 year. It decreases "on-off" fluctuations. Rasagiline (Azilect) is an MAO-B inhibitor used for the treatment of parkinsonism.

Large doses of selegiline may inhibit MAO-A, an enzyme that promotes metabolism of tyramine in the GI tract. If they are not metabolized by MAO-A, ingestion of foods high in tyramine (aged cheese, red wine, and bananas) can cause a hypertensive crisis. Severe adverse drug interactions can occur between selegiline and various tricyclic antidepressants (TCA) or selective serotonin reuptake inhibitors (SSRIs).

COMT Inhibitors

The enzyme catechol *O*-methyltransferase (COMT) inactivates dopamine. When taken with a levodopa preparation, COMT inhibitors increase the amount of levodopa concentration in the brain. Tolcapone (Tasmar) was the first COMT inhibitor taken with levodopa for advanced parkinsonism. This drug can affect liver cell function; therefore serum liver enzymes should be closely monitored. Entacapone (Comtan) does not affect liver function. In 2003, the FDA approved a combination drug of dopaminergics (carbidopa and levodopa) and a COMT inhibitor (entacapone) called Stalevo. With various dosage strengths available, Stalevo provides greater dosing flexibility and individualization to the patient. This combination of three drugs lessens the "wearing off" effects of levodopa that are sometimes experienced prior to the next dose.

Table 23-3 lists dopaminergics, dopamine agonists, MAO-B inhibitors, and COMT inhibitors with their dosages, uses, and considerations.

TABLE 23-3 ANTIPARKINSON: DOPAMINERGICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Dopaminergics		
carbidopa-levodopa (Sinemet)	See Prototype Drug Chart 23-1.	
Dopamine Agonists		
amantadine HCl (Symmetrel)	Parkinsonism: A: PO: 100 mg b.i.d.; may increase dose; *max:* 400 mg/d	For early-onset parkinsonism, drug-induced parkinsonism, and influenza A respiratory virus. Effective for rigidity and bradykinesia; less effective for decreasing tremors. May be used alone or in combination. Has fewer side effects than anticholinergic drugs. Pregnancy category: C; PB: 60%-70%; t½: 11-15 h
bromocriptine mesylate (Parlodel)	A: PO: Initially 1.25-2.5 mg/d; may gradually increase dose; maint: 30-60 mg/d in 3 divided doses; *max:* 100 mg/d	To treat parkinsonism. Response is better than with amantadine. Can be taken in adjunct with levodopa or carbidopa-levodopa. Hypotension, lightheadedness, and syncope are major side effects. Initially, small doses are given and then gradually increased over several weeks. Pregnancy category: B; PB: 90%-96%; t½: 6-8 h; terminal phase: 50 h
pramipexole dihydrochloride (Mirapex)	A: PO: Initially: 0.125 mg t.i.d.; maint: 1.5 mg t.i.d.; *max:* 4.5 mg/d	To treat parkinsonism. Stimulates dopamine receptors in striatum. May cause dizziness, postural hypotension, hallucinations. Pregnancy category: C; PB: 15%; t½: 8-12 h
ropinirole HCl (Requip)	A: PO: Initially: 0.25 mg t.i.d.; *max:* 24 mg/d	To treat parkinsonism. Stimulates dopamine receptors in striatum. May cause nausea, fatigue, somnolence. Pregnancy category: C; PB: 40%; t½: 6 h
MAO-B Inhibitors		
selegiline HCl (Eldepryl)	A: PO: 5 mg b.i.d.; *max:* 10 mg/d	For early-onset parkinsonism. May delay use of levodopa therapy by 1 y. Can be given with levodopa preparations; dose of levodopa would need to be decreased. May cause suicidal ideation. Pregnancy category: C; PB: 85%; t½: 2-20 h
rasagiline (Azilect)	A: PO: 0.5-1 mg/d	For treatment of Parkinsonism. Pregnancy category: C; PB: 88%-94%; t½: 3 h
COMT Inhibitors		
tolcapone (Tasmar)	A: PO: 100 mg t.i.d.; *max:* 600 mg/d	For treatment of parkinsonism. Potentiates dopamine activity by inhibiting COMT. Used in conjunction with levodopa-carbidopa (Sinemet); prolongs action of levodopa. Monitor liver enzymes frequently as may cause fatal hepatotoxicity. Pregnancy category: C; PB: 99%; t½: 2-3 h
entacapone (Comtan)	A: PO: 200 mg with each dose of levodopa-carbidopa; *max:* 1600 mg/d	Used in combination with levodopa-carbidopa. Prevents peripheral COMT; thus more levodopa reaches the brain. Prolongs half-life of levodopa and decreases "on-off" fluctuations. Levodopa dose should be decreased when taken with a COMT inhibitor. Pregnancy category: C; PB: 98%; t½: 1-2 h

A, Adult; *COMT,* catechol *O*-methyltransferase; *d,* day; *GI,* gastrointestinal; *h,* hour; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *>,* greater than.

Nursing Process
Patient-Centered Collaborative Care

Antiparkinson: Dopaminergic Agent: Carbidopa-Levodopa

Assessment
- Obtain patient's vital signs to use for future comparison.
- Assess patient for signs and symptoms of parkinsonism, including stooped forward posture, shuffling gait, masked facies, and resting tremors.
- Obtain a history from patient of glaucoma, heart disease, peptic ulcers, kidney or liver disease, and psychosis.
- Obtain a drug history. Report if drug-drug interaction is probable. Drugs that should be avoided or closely monitored are levodopa, bromocriptine, and anticholinergics.

Nursing Diagnoses
- Impaired physical mobility related to dizziness
- Risk for activity intolerance related to fatigue
- Risk for falls related to shuffling gait
- Knowledge deficit related to unfamiliar medications

Planning
- Patient's symptoms of parkinsonism will be decreased or absent after 1 to 4 weeks of drug therapy.

Nursing Interventions
- Monitor patient's vital signs and electrocardiogram. Orthostatic hypotension may occur during early use of levodopa and bromocriptine. Instruct patient to rise slowly to avoid faintness.
- Observe for weakness, dizziness, or syncope, which are symptoms of orthostatic hypotension.
- Administer carbidopa-levodopa (Sinemet) with low-protein foods. High-protein diets interfere with drug transport to the CNS.
- Observe for symptoms of parkinsonism.

Patient Teaching

General
- Urge patient not to abruptly discontinue the medication. Rebound parkinsonism (increased symptoms of parkinsonism) can occur.
- Inform patient that urine may be discolored and will darken with exposure to air. Perspiration also may be dark. Explain that both are harmless but clothes may be stained.
- Advise patient to avoid chewing or crushing extended-release tablets.

Side Effects
- Encourage patient to report side effects and symptoms of dyskinesia. Explain to patient that it may take weeks or months before symptoms are controlled.

Diet
- Suggest to patient that taking levodopa with food may decrease GI upset, but food will slow the drug absorption rate.
- Urge patient who takes high doses of selegiline to avoid foods high in tyramine (e.g., aged cheese, red wine, cream, yogurt, chocolate, bananas, raisins) to prevent hypertensive crisis.

Amantadine and Bromocriptine
- Urge patient taking amantadine to report any signs of skin lesions, seizures, or depression. A history of these health problems should have been previously reported to health care provider.
- Advise patient taking bromocriptine to report symptoms of lightheadedness when changing positions (a symptom of orthostatic hypotension).
- Warn patient to avoid alcohol when taking bromocriptine.
- Teach patient to check heart rate and report changes in rate or irregularity.
- Counsel patient not to abruptly stop the drug without first notifying health care provider.

Cultural Considerations
- Recognize that various cultural groups will need guidance in understanding the disease process of parkinsonism. Support patient and family member who may be dismayed about the symptoms of parkinsonism and lack knowledge of the disease process.
- Secure an interpreter for patient who speaks little or no English to support understanding of drug doses and schedules and recognition of severe side effects that need to be reported to health care provider.

Evaluation
- Evaluate effectiveness of drug therapy in controlling symptoms of parkinsonism.
- Determine if there is an absence of side effects.

Determine if patient and family has increased knowledge of drug regimen.

Precautions for Drugs Used to Treat Parkinsonism

Side Effects and Adverse Reactions

The common side effects of anticholinergics include dry mouth and dry secretions, urinary retention, constipation, blurred vision, and an increase in heart rate. Mental effects such as restlessness and confusion may occur in the older adult.

The side effects of carbidopa-levodopa are numerous. GI disturbances are common because dopamine stimulates the chemoreceptor trigger zone (CTZ) in the medulla, which stimulates the vomiting center. Taking the drug with food can decrease nausea and vomiting, but food slows the absorption rate. **Dyskinesia** (impaired voluntary movement) may occur with high levodopa dosages. Cardiovascular side effects include orthostatic hypotension and increased heart rate during early use of levodopa. Cardiac dysrhythmias may occur as carbidopa-levodopa dosages are increased. Nightmares, mental disturbances, and suicidal tendencies may occur.

Amantadine has few side effects, but they can intensify when the drug is combined with other antiparkinson drugs. Orthostatic hypotension, confusion, urinary retention, and constipation are common side effects of amantadine.

Side effects from bromocriptine are more common than from amantadine. These include GI disturbances (nausea), orthostatic hypotension, palpitations, chest pain, lower extremity edema, nightmares, delusions, and confusion. If bromocriptine is taken with carbidopa-levodopa, usually the drug dosages are reduced and side effects and drug intolerance decrease.

Pramipexole (Mirapex) and ropinirole (Requip) can cause nausea, dizziness, somnolence, weakness, and constipation. These drugs intensify the dyskinesia and hallucinations caused by levodopa. In 2006, pramipexole was FDA approved for treatment of restless legs syndrome.

Large doses of selegiline (Eldepryl) may inhibit MAO-A. Hypertensive crisis might occur if foods high in tyramine such as aged cheese, red wine, and bananas are ingested concurrently.

Tolcapone (Tasmar) may cause severe liver damage. Patients with liver dysfunction should not take this drug. Entacapone (Comtan) is not known to affect liver function. With entacapone, the urine can be dark yellow to orange; with tolcapone, the urine can be bright yellow. Both tolcapone and entacapone can intensify the adverse reactions of levodopa (e.g., hallucinations, orthostatic hypotension, constipation, dizziness) because these drugs prolong the effect of levodopa.

Contraindications

Anticholinergics or any drugs that have anticholinergic effects are contraindicated for persons with glaucoma. Persons with severe cardiac, renal, or psychiatric health problems should avoid levodopa drugs because of adverse reactions. Patients with chronic obstructive lung diseases such as emphysema can have dry, thick mucous secretions caused by large doses of anticholinergic drugs.

Drug-Drug Interactions

Antipsychotic drugs block the receptors for dopamine. Carbidopa-levodopa taken with a monoamine oxidase inhibitor (MAOI) antidepressant can cause a hypertensive crisis.

ALZHEIMER'S DISEASE

Alzheimer's disease is an incurable dementia illness characterized by chronic, progressive neurodegenerative conditions with marked cognitive dysfunction. Onset usually occurs between 45 and 65 years of age.

Pathophysiology

Many physiologic changes contribute to Alzheimer's disease. Currently, theories related to the changes that cause Alzheimer's disease include the following:

- Degeneration of the cholinergic neuron and deficiency in acetylcholine
- Neuritic plaques that form mainly outside of the neurons and in the cerebral cortex
- Apolipoprotein E_4 (apo E_4) that promotes formation of neuritic plaques, which binds beta-amyloid in the plaques
- Beta-amyloid protein accumulation in high levels that may contribute to neuronal injury
- Presence of neurofibrillary tangles with twists inside the neurons

Figure 23-2 illustrates the normal neuron and the neuron affected by Alzheimer's disease. The etiology of Alzheimer's disease is unknown. Factors thought to influence the occurrence of Alzheimer's disease are genetic predisposition, virus, infection, or inflammation that attacks brain cells, as well as nutritional, environmental, and immunologic.

Symptoms of Alzheimer's disease include memory loss, confusion, inability to communicate, aggressive behavior, depression, and psychoses (Table 23-4). With memory loss,

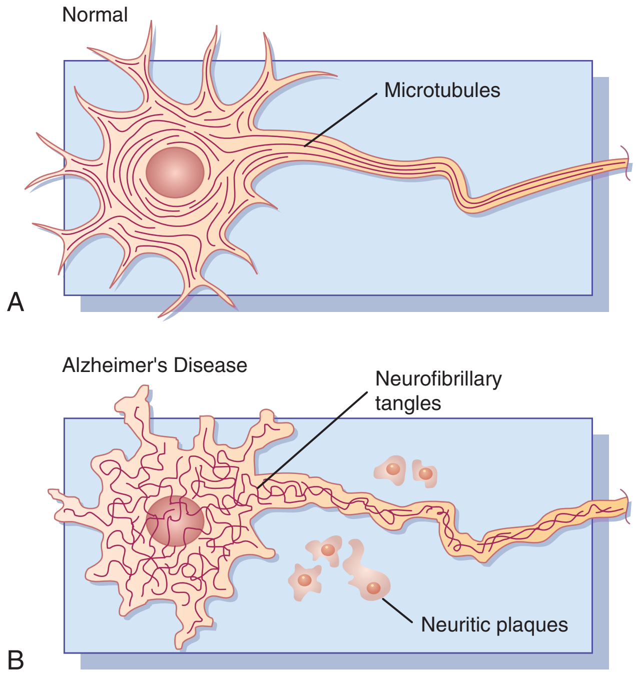

FIGURE 23–2 Histologic changes in Alzheimer's disease. **A**, Healthy neuron. **B**, Neuron affected by Alzheimer's disease showing characteristic neuritic plaques and cellular neurofibrillary tangles.

TABLE 23-4 STAGES OF COGNITIVE DECLINE DUE TO ALZHEIMER'S DISEASE

STAGE	CLINICAL PHASE	SYMPTOMS
1	Normal	No change in cognition
2	Very mild	Forgets object location; some deficit in word-finding
3	Mild (early confusion)	Early cognitive decline in one or more areas, memory loss, decreased ability to function in work situation, name-finding deficit, some decrease in social functioning, recall difficulties, anxiety
4	Moderate	Unable to perform complex tasks such as managing personal finances, planning a dinner party, concentrating, and knowing current events
5	Moderately severe (early dementia)	Usually needs assistance for survival, reminders to bathe, help in selecting clothes and other daily functions; may be disoriented as to time and recent events, although this can fluctuate; may become tearful
6	Severe (dementia)	Needs assistance with dressing, bathing, and toilet functions (e.g., flushing); may forget names of spouse, family, or caregivers and details of their personal lives; generally unaware of their surroundings; incontinence of urine and feces may occur; CNS disturbances such as agitation, delusions, paranoia, obsessive anxiety, and potential for violent behavior may increase
7	Very severe (late dementia)	Unable to speak (speech limited to five words or fewer); may scream or make other sounds; unable to ambulate, sit up, smile, or feed self; unable to hold head erect; ultimately slips into stupor or coma

logical thinking and judgment and time disorientation is also lost. As the disease progresses, memory loss becomes more severe; personality changes occur; and hyperactivity, hostility, paranoia, tendency to wander, and the inability to speak or express oneself result. Custodial care becomes necessary.

Acetylcholinesterase Inhibitors/Cholinesterase Inhibitors

There is no known cure for Alzheimer's disease. FDA-approved medications to treat Alzheimer's disease symptoms include **acetylcholinesterase (AChE) inhibitors.** (AChE is an enzyme responsible for breaking down ACh and is also known as *cholinesterase.*) The AChE inhibitors are tacrine (Cognex); donepezil (Aricept); and rivastigmine (Exelon), drug that permits more acetylcholine in the neuron receptors. Rivastigmine has effective penetration into the CNS; thus, cholinergic transmission is increased. These AChE inhibitors increase cognitive function for patients with mild to moderate Alzheimer's disease. A reversible AChE inhibitor used to treat mild to moderate Alzheimer's disease is galantamine (Razadyne).

Several drugs for treating Alzheimer's disease are under investigation. Some of these are certain nonsteroidal antiinflammatory drugs (piroxicam, indomethacin), calcium channel blockers, MAO-B inhibitors (selegiline), serotonin antagonists, CNS stimulants (methylphenidate [Ritalin]), angiotensin-converting enzyme (ACE) inhibitors, and Vitamin E.

Rivastigmine

Rivastigmine (Exelon), an AChE inhibitor, is prescribed to improve cognitive function for patients with mild to moderate Alzheimer's disease (Prototype Drug Chart 23-2). This drug increases the amount of ACh at the cholinergic synapses. Rivastigmine tends to slow the disease process. Rivastigmine has fewer drug interactions than donepezil. Table 23-5 lists the AChE inhibitors used to treat Alzheimer's disease.

Pharmacokinetics Rivastigmine is absorbed faster through the GI tract without food. It has a relatively short half-life and is given twice a day. The dose is gradually increased. The protein-binding power is average.

Pharmacodynamics Rivastigmine has been successful in improving memory in mild to moderate Alzheimer's disease. The onset of action is 0.5 to 1.0 hour for topical application; peak action is 8 to 16 hours. When given orally, the peak is 1 hour. This drug is contraindicated for patients with liver disease because hepatotoxicity may occur. Cumulative drug effect is likely to occur in older adults and in patients with liver and renal dysfunction.

Nursing Process
Patient-Centered Collaborative Care

Drug Treatment for Alzheimer's Disease: Rivastigmine

Assessment

- Assess patient's mental and physical abilities. Note limitation of cognitive function and self-care.
- Obtain a history of liver or renal disease or dysfunction.
- Assess for memory and judgment losses. Elicit from family members a history of behavioral changes (e.g., memory loss, declining interest in people or home, difficulty in following through with simple activities, and tendency to wander from home).
- Observe for signs of behavioral disturbances such as hyperactivity, hostility, and wandering.
- Examine patient for signs of aphasia or difficulty in speech.
- Note patient's motor function.
- Determine family members' ability to cope with patient's mental and physical changes.

PROTOTYPE DRUG CHART 23-2

Rivastigmine

Drug Class
Acetylcholinesterase inhibitor
Trade Name: Exelon
Pregnancy Category: B

Dosage
A: PO: Initially: 1.5 mg b.i.d.; increase gradually
Maintenance: 3-6 mg b.i.d.; *max:* 12 mg/d

Contraindications
Liver and renal diseases, urinary tract obstruction, orthostatic hypotension, bradycardia
Caution: Asthma, COPD, seizures, peptic ulcer disease

Drug-Lab-Food Interactions
Drug: Increase effect of theophylline, general anesthetics; TCAs decrease effect; increase effect with cimetidine; NSAIDs increase GI effects; tobacco increases clearance of rivastigmine
Lab: Increase ALT, AST

Pharmacokinetics
Absorption: PO: Food decreases absorption rate
Distribution: PB: 40%
Metabolism: $t_{1/2}$: 1 h
Excretion: In urine

Pharmacodynamics
PO: Onset: UK
Peak: 1 h
Duration: UK

Therapeutic Effects/Uses
Improves memory loss
Mode of Action: Elevates acetylcholine concentration

Side Effects
Anorexia, nausea, vomiting, diarrhea, constipation, abdominal pain, gastrointestinal bleeding, dizziness, depression, peripheral edema, dry mouth, dehydration, restless legs syndrome, nystagmus

Adverse Reactions
Seizures, bradycardia, orthostatic hypotension, cataracts, myocardial infarction, heart failure
Life-threatening: Hepatotoxicity, suicidal ideation, Stevens-Johnson syndrome

A, Adult; *ALP,* alkaline phosphatase; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *b.i.d.,* two times a day; *BUN,* blood urea nitrogen; *h,* hour; *LDH,* lactic dehydrogenase; *maint,* maintenance; *MAOIs,* monoamine oxidase inhibitors; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; $t_{1/2}$, half-life; *t.i.d.,* three times a day; *UK,* unknown.

TABLE 23-5 ACETYLCHOLINESTERASE (ACHE) INHIBITORS FOR ALZHEIMER'S DISEASE

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
donepezil (Aricept)	A: PO: 5-10 mg h.s.	Increases acetylcholine by inhibiting AChE to treat mild to moderate phase of Alzheimer's disease. Pregnancy category: C; PB: 96%; $t_{1/2}$: 70 h
rivastigmine (Exelon)	See Prototype Drug Chart 23-2.	
tacrine HCl (Cognex)	A: PO: Initially 10 mg q.i.d.; after 4 wk, increase every other wk; *max:* 160 mg/d in 4 divided doses.	To treat mild to moderate Alzheimer's disease. AChE inhibitor. Has increased incidence of peripheral cholinergic side effects. Pregnancy category: C; PB: UK; $t_{1/2}$: 1.5-4 h
memantine (Namenda)	A: PO: 5 mg/d, may increase dose in 5-mg increments every week to 10 mg/d; *max:* 20 mg/d	To treat mild to severe Alzheimer's disease. Neurotransmitter inhibitor. Pregnancy category: B; PB: 45%; $t_{1/2}$: 60-80 h
galantamine (Razadyne)	A: PO: Initially 4 mg b.i.d., may increase 4 mg every 4 wk if well tolerated; maint: 12 mg b.i.d.; *max:* 24 mg/d	To treat mild to moderate Alzheimer's disease. Reversible AChE inhibitor. Pregnancy category: B; PB: 18%; $t_{1/2}$: 7 h

A, Adult; *AChE,* acetylcholinesterase; *b.i.d.,* twice a day; *d,* day; *GI,* gastrointestinal; *h,* hour; *h.s.,* at bedtime; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; $t_{1/2}$, half-life; *UK,* unknown; *wk,* week.

Nursing Diagnoses

- Feeding self-care deficit related to memory loss
- Bathing self-care deficit related to memory loss
- Toileting self-care deficit related to memory loss
- Chronic confusion related to memory loss
- Interrupted family processes related to decreased cognition
- Compromised family coping related to overwhelming disruption of lifestyle
- Risk for injury related to hyperactivity and dizziness

- Imbalanced nutrition related to anorexia, nausea, and vomiting

Planning

- Patient's memory will be improved.
- Patient will maintain self-care of body functions with assistance.

Nursing Interventions

- Maintain consistency in care.
- Assist patient in ambulation and activity.
- Monitor for side effects related to continuous use of AChE inhibitors.
- Record vital signs periodically. Note signs of bradycardia and hypotension.
- Observe patient's behavioral changes, and record improvement or decline

Patient Teaching

General

- Explain to patient and family the purpose for prescribed drug therapy.
- Clarify time for drug dosing and schedule for increasing drug dosing to family member responsible for patient's medications.
- Teach family member about safety techniques (e.g., removing obstacles from patient's path so that patient can avoid injury when wandering).
- Inform family member of available support groups such as the Alzheimer's Disease and Related Disorders Association.

Side Effects

- Inform patient and family member that patient should rise slowly to avoid dizziness and loss of balance.
- Monitor routine liver function tests, as hepatotoxicity is an adverse effect.

Diet

- Inform family member about foods that may be prepared for patient's consumption and tolerance.

Cultural Considerations

- Recognize that various cultural groups may need guidance in understanding the disease process of Alzheimer's disease.
- Communicate respect for variant cultural beliefs and practices; help family members understand that their family member has a neurologic problem that may be part of the aging process. Explain how symptoms may become more progressive.

Evaluation

- Evaluate effectiveness of drug regimen by determining if patient's mental and physical status shows improvement from drug therapy

CRITICAL THINKING CASE STUDY

TR, a 79-year-old man, was diagnosed with Parkinson's disease 10 years ago. During his early treatment, he took selegiline. The drug dosage was increased to alleviate symptoms.

1. How does selegiline alleviate symptoms of parkinsonism?
2. What dietary changes should be made during the time TR takes selegiline?

Because TR developed numerous side effects and adverse reactions to selegiline, the health care provider changed the drug to carbidopa-levodopa (Sinemet). TR asks the nurse why the drug was changed.

3. What are the similarities and differences between selegiline and Sinemet?
4. What are the advantages of carbidopa-levodopa?

TR's family says they know a person with Parkinson's disease who takes the antiviral drug amantadine (Symmetrel). The family asks whether Symmetrel is the same as Sinemet and, if so, whether TR can take that drug instead of a drug containing carbidopa-levodopa.

5. What is the effect of amantadine on symptoms of parkinsonism?
6. What would be an appropriate response to the family's question concerning the use of Symmetrel for TR?
7. What are the uses for dopamine agonists and COMT inhibitors?
8. Certain anticholinergic drugs may be used to control parkinsonism symptoms. What is the action of these drugs, and what are their side effects? These anticholinergic drugs are usually prescribed for parkinsonism symptoms resulting from what?

NCLEX STUDY QUESTIONS

1. Which of the following assessment findings could the nurse see in a patient with parkinsonism? (Select all that apply.)
   a. An abrupt onset of symptoms
   b. Muscle rigidity
   c. Involuntary tremors
   d. Bradykinesia
   e. Bilateral muscle weakness

2. A patient is receiving carbidopa-levodopa for parkinsonism. What should the nurse know about this drug?
   a. Carbidopa-levodopa may lead to hypertension.
   b. Carbidopa-levodopa may lead to excessive salivation.
   c. Dopaminergic and anticholinergic therapy may lead to drowsiness and sedation.
   d. Dopaminergics and anticholinergics are contraindicated in patients with glaucoma.

3. The nurse has initiated teaching for a family member of a patient with Alzheimer's disease. The nurse realizes more teaching is needed if the family member makes which statement?
   a. As the disease gets worse, the memory loss will get worse.
   b. There are several theories about the cause of the disease.
   c. Personality changes and hostility may occur.
   d. It may take several medications to cure the disease.

4. A patient is taking rivastigmine (Exelon). The nurse should teach the patient and family which information about rivastigmine?
   a. That hepatotoxicity may occur
   b. That the initial dose is 6 mg t.i.d.
   c. That GI distress is a common side effect
   d. That weight gain may be a side effect

5. Which is a nursing intervention for a patient taking carbidopa-levodopa for parkinsonism?
   a. Encourage the patient to adhere to a high-protein diet.
   b. Inform the patient that perspiration may be dark and stain clothing.
   c. Advise the patient that glucose levels should be checked with urine testing.
   d. Warn the patient that it may take 4 to 5 days before symptoms are controlled.

6. What would the nurse teach a patient who is taking anticholinergic therapy for parkinsonism? (Select all that apply.)
   a. Avoid alcohol, cigarettes, and caffeine.
   b. Relieve dry mouth with hard candy or ice chips.
   c. Use sunglasses to reduce photophobia.
   d. Urinate 2 hours after taking the drug.
   e. Receive routine eye examinations.

7. A patient is taking rivastigmine (Exelon) to improve cognitive function. What should the nurse teach the patient/family member to do? (Select all that apply.)
   a. Rise slowly to avoid dizziness.
   b. Remove obstacles from pathways to avoid injury.
   c. Closely follow the drug dosing schedule.
   d. Have frequent checks for hypertension.
   e. Receive regular liver function tests.

Answers: 1, b, c, d; 2, d; 3, d; 4, c; 5, b; 6, a, b, c, e; 7, a, b, c.

CHAPTER

Drugs for Neuromuscular Disorders: Myasthenia Gravis, Multiple Sclerosis, and Muscle Spasms

evolve WEBSITE

http://evolve.elsevier.com/KeeHayes/pharmacology/

- Animations
- Content Updates
- Key Points
- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Contrast the pathophysiology of myasthenia gravis and multiple sclerosis.
- Discuss the drug group used to treat myasthenia gravis.
- Compare the treatment strategies for the three phases of multiple sclerosis.
- Differentiate between the muscle relaxants used for spasticity and those used for muscle spasms.
- Apply the nursing process to drugs used to treat myasthenia gravis and muscle spasms.

multiple sclerosis, p. 326
muscle relaxants, p. 327
muscle spasms, p. 326
myasthenic crisis, p. 327
myasthenia gravis, p. 326

Myasthenia gravis (MG), a lack of nerve impulses and muscle responses at the myoneural (nerves in muscle endings) junction, causes fatigue and muscular weakness of the respiratory system, facial muscles, and extremities. Because of cranial nerve involvement, ptosis (drooping eyelid) and difficulty in chewing and swallowing occur. Respiratory arrest may result from respiratory muscle paralysis. The symptoms of MG are caused by autoimmune destruction of acetylcholine (ACh) receptor sites and a resultant decrease in neuromuscular transmission.

The neuromuscular disorder **multiple sclerosis** (MS) attacks the myelin sheath of nerve fibers, causing lesions known as *plaques.* While there are no definitive diagnostic tests, the sclerotic plaques are usually detected and measured by magnetic resonance imaging (MRI). Pharmacologic treatment is necessary to control the symptoms of this disorder.

Muscle spasms have various causes, including injury or motor neuron disorders that lead to conditions such as cerebral palsy, MS, spinal cord injuries (paraplegia [paralysis of

the legs]), cerebral vascular accident (stroke), or hemiplegia (paralysis of one side of the body). Spasticity of muscles can be reduced with the use of skeletal **muscle relaxants**.

MYASTHENIA GRAVIS

MG is a chronic autoimmune neuromuscular disease that affects approximately 14 in 100,000 persons. It can occur at any age; however, MG occurs more commonly in women younger than 30 years and in men older than 50 years. It is not a genetic disorder, but there can be a familial tendency.

Pathophysiology

MG results from a lack of ACh receptor sites. This autoimmune disorder involves an antibody response against an alpha subunit of the acetylcholine receptor (AChR) site at the neuromuscular junction. Antibodies attack AChR sites, obstructing the binding of ACh and eventually destroying receptor sites. When AChR sites are reduced, ACh molecules are prevented from binding to receptors and stimulating normal neuromuscular transmission. The result is ineffective muscle contraction and muscle weakness. About 90% of patients with MG have anti-acetylcholine antibodies that can be detected through serum testing.

The thymus gland is involved in systemic immunity that is active during infancy and early childhood, but the gland normally shrinks during adulthood. Approximately 60% of MG patients have thymic hyperplasia. It has been suggested in some cases that if the thymus gland is removed during the early onset of MG, clinical symptoms are greatly decreased. Thymectomy has been an option for patients younger than 50 years.

MG is characterized primarily by weakness and fatigue of the skeletal (voluntary) muscles. Other characteristics of MG include dysphagia (difficulty chewing and swallowing), dysarthria (slurred speech), and respiratory muscle weakness. Early symptoms of MG are ptosis (drooping eyelids) and diplopia (double vision).

The group of drugs used to control MG is the AChE inhibitors, also called *cholinesterase inhibitors* and *anticholinesterase;* they inhibit the action of the enzyme. As a result of this action, more acetylcholine is available to activate the cholinergic receptors and promote muscle contraction. The AChE inhibitors are classified as parasympathomimetics.

When muscular weakness of the patient with MG becomes generalized, **myasthenic crisis** may occur. This complication is a severe generalized muscle weakness and may involve the muscles of respiration, such as the diaphragm and intercostal muscles. Triggers of myasthenic crisis include inadequate dosing of AChE inhibitors, infection, emotional stress, menses, pregnancy, surgery, trauma, hypokalemia, temperature extremes, and alcohol intake. Myasthenic crisis can also occur three to four hours after taking certain medications (e.g., aminoglycoside and fluoroquinolone antibiotics, calcium channel blockers, phenytoin [Dilantin], and psychotropics). If muscle weakness remains untreated, death could result from paralysis of the respiratory muscles. Neostigmine (Prostigmin), a fast-acting AChE inhibitor, can relieve myasthenia crisis.

Overdosing with AChE inhibitors may cause another complication of MG called **cholinergic crisis,** which is an acute exacerbation of symptoms. A cholinergic crisis usually occurs within 30 to 60 minutes after taking anticholinergic medications. This complication is due to continuous depolarization of postsynaptic membranes that create neuromuscular blockade. The patient with cholinergic crisis often has severe muscle weakness that can lead to respiratory paralysis and arrest. Accompanying symptoms include **miosis** (abnormal pupil constriction), pallor, sweating, vertigo, excess salivation, nausea, vomiting, abdominal cramping, diarrhea, bradycardia, and **fasciculations** (involuntary muscle twitching).

Acetylcholinesterase Inhibitors/Cholinesterase Inhibitors

The first drug used to manage MG was neostigmine. It is a short-acting **acetylcholinesterase (AChE) inhibitor** with a half-life of 0.5 to 1 hour. The drug is given every 2 to 4 hours and must be given on time to prevent muscle weakness. The AChE inhibitor pyridostigmine bromide (Mestinon) has an intermediate action and is given every 3 to 6 hours. Ambenonium chloride (Mytelase) is a long-acting AChE inhibitor and is usually prescribed when the patient does not respond to neostigmine or pyridostigmine. Prototype Drug Chart 24-1 presents drug data related to pyridostigmine. Table 24-1 lists the AChE inhibitors. Cholinesterase inhibitors are discussed in Chapter 23.

Pharmacokinetics Pyridostigmine is poorly absorbed from the GI tract. Half of the sustained-release capsule is absorbed readily, but the balance is poorly absorbed. The duration of oral pyridostigmine is 3.5 to 4 hours; when given intravenously (IV), it is 2 hours. Because of its short half-life, pyridostigmine must be administered several times a day. The drug is metabolized by the liver and excreted in the urine.

Pharmacodynamics Pyridostigmine increases muscle strength of patients with muscular weakness resulting from MG. The onset of action of oral preparations is 0.5 to 1 hour. The duration of action is longer with the sustained-release drug capsule. One thirtieth of the oral dose of pyridostigmine can be administered IV. Overdosing of pyridostigmine can result in signs and symptoms of cholinergic crisis (i.e., extreme muscle weakness; increased salivation, tears, sweating; miosis); the antidote atropine sulfate should be available. This crisis requires emergency medical intervention because of respiratory muscle weakness.

Patients who do not respond to AChE inhibitors may require prednisone, plasma exchange, intravenous immune globulin (IVIG), or immunosuppressive drugs. Prednisone decreases MG symptoms and promotes remission, but long-term use can cause adverse dermatologic effects.

The immunosuppressive agent azathioprine (Imuran) can be used in conjunction with a lower dose of prednisone. With azathioprine, the white blood cell (WBC) count and liver enzymes should be closely monitored to avoid leukopenia and hepatotoxicity.

Overdosing and underdosing of AChE inhibitors have similar symptoms: muscle weakness, dyspnea (difficulty breathing), and dysphagia (difficulty swallowing). Additional symptoms that may be present with overdosing are increased salivation (drooling), bradycardia, abdominal cramping, and increased tearing and sweating. All doses of AChE inhibitors should be administered *on time,* because late administration of the drug could result in muscle weakness.

Underdosing can result in myasthenia crisis, and overdosing can result in cholinergic crisis. Edrophonium chloride (Tensilon) is an

PROTOTYPE DRUG CHART 24-1

Pyridostigmine

Drug Class Cholinesterase inhibitor Trade Name: Mestinon Pregnancy Category: C	**Dosage** A: PO: 60-120 mg in 5 to 6 doses per day; *max:* 600 mg/d in divided doses SR: 180-540 mg q.d./b.i.d., with at least 6 hours between doses; *max:* 1.5 g/d A: IM/IV: 2 mg q2-3h C: PO: 7 mg/kg/d in 5-6 divided doses C: IV/IM: 0.05-0.15 mg/kg; *max single dose:* 10 mg
Contraindications GI and GU mechanical obstruction, severe renal disease, ileus Caution: Asthma, hypotension, bradycardia, seizure disorder, peptic ulcer, cardiac dysrhythmias, renal dysfunction, hyperthyroidism, pregnancy, breastfeeding	**Drug-Lab-Food Interactions** Drug: Decrease pyridostigmine effect with atropine, corticosteroids, muscle relaxants, antidysrhythmics, aminoglycosides, anesthetics, magnesium, fluoroquinolones; increase toxicity with cholinesterase inhibitors, insecticides, atropine, tetracyclines, polymyxin B
Pharmacokinetics Absorption: PO: Poorly absorbed; SR: 50% absorbed Distribution: PB: UK Metabolism: t½: PO: 3.5-4 h; IV: 2 h Excretion: In urine	**Pharmacodynamics** PO: Onset: 30-45 min Peak: UK Duration: 3-6 h PO SR: Onset: 0.5-1 h Peak: UK Duration: 6-12 h IM: Onset: 15 min Peak: UK Duration: 2-4 h IV: Onset: 2-5 min Peak: UK Duration: 2-3 h
Therapeutic Effects/Uses To control and treat myasthenia gravis. Also used as a nondepolarizing muscle relaxant antagonist, and as an anti–nerve gas agent for U.S. military personnel for use in the immediate threat of the nerve gas Soman Mode of Action: Transmission of neuromuscular impulses by preventing destruction of acetylcholine	
Side Effects Nausea, vomiting, diarrhea, headache, blurred vision, dizziness, abdominal cramps, excess saliva and sweating, rash, miosis	**Adverse Reactions** Hypotension, bradycardia Life-threatening: Dyspnea, bronchospasm, cardiac dysrhythmias, seizures

A, Adult; *ALP,* alkaline phosphatase; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *b.i.d.,* twice a day; *BUN,* blood urea nitrogen; *C,* child; *d,* day; *GI,* gastrointestinal; *GU,* genitourinary; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *LDH,* lactic dehydrogenase; *MAOIs,* monoamine oxidase inhibitors; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *q.d.,* every day; *q.i.d.,* four times a day; *SR,* sustained release; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown.

ultra–short-acting AChE inhibitor that may be used to distinguish between myasthenia crisis and cholinergic crisis. These two different crises have a similar major symptom: severe muscle weakness. After edrophonium is administered, if the symptoms are alleviated because of an increase in ACh, the cause is myasthenia crisis. However, if the muscle weakness becomes more severe, the cause is cholinergic crisis due to drug overdosing.

Edrophonium may also be used to diagnose MG. Its ultra-short duration of 5 to 20 minutes increases muscle strength immediately. If ptosis is immediately corrected after administration of this drug, the diagnosis is most likely MG.

Side Effects and Adverse Reactions

Side effects and adverse reactions of AChE inhibitors include GI disturbances (nausea, vomiting, diarrhea, abdominal cramps) and increased salivation and tearing. Other side effects include miosis (constricted pupil of the eye), blurred vision, bradycardia, and hypotension.

Nursing Process
Patient-Centered Collaborative Care

Drug Treatment for Myasthenia Gravis: Pyridostigmine (Mestinon)

Assessment

- Obtain a drug history of drugs patient currently takes. Report if a drug-drug interaction is likely. Patient should avoid atropine, atropine-like drugs, and muscle relaxants.
- Record baseline vital signs for future comparison.
- Assess patient for signs and symptoms of myasthenia crisis such as muscle weakness with difficulty breathing and swallowing.

TABLE 24-1 ACETYLCHOLINESTERASE (ACHE) INHIBITORS: MYASTHENIA GRAVIS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Ambenonium (Mytelase)	A: PO: 2.5-5.0 mg t.i.d./q.i.d.; dose may be increased; *maint:* 15-100 mg/d	For myasthenia gravis. A long-acting AChE inhibitor. Six times more potent than neostigmine. Frequently used when patient cannot take neostigmine or pyridostigmine because of the bromide component. Can be taken in adjunct with glucocorticoid drug. Pregnancy category: C; PB: UK; t½: UK
Edrophonium (Tensilon)	A: IV 2 mg; then 8 mg if no response A: IM: 10 mg; if cholinergic reaction occurs, retest after 30 min with 2 mg to rule out false-negative. C <34 kg: IV: 1 mg, repeat in 45 sec if no response; *max:* 5 mg C >34 kg: IV: 2 mg, repeat with 1 mg if no response; *max:* 10 mg	For diagnosing myasthenia gravis. Ptosis should be absent in 1-5 min. Ultrashort-acting drug. Pregnancy category: C; PB: UK; t½: 1.2-2 h
neostigmine (Prostigmin)	A: PO: 15 mg t.i.d., may increase to 375 mg/d A: IV/IM/subQ: 0.5-2.5 mg q1-3h; *max:*10 mg/d C: PO: 0.033 mg/kg every 3-4 h C: IV/IM/subQ: 0.01-0.04 mg/kg every 2-4 h	For controlling myasthenia gravis. Must be given on time to prevent myasthenia crisis. Parenteral route is used if chewing, swallowing, and breathing are affected. Overdose can cause cholinergic reaction, nausea, abdominal cramps, excessive salivation, and sweating. Pregnancy category: C; PB: 15%-25%; t½: 42-60 min
pyridostigmine (Mestinon)	See Prototype Drug Chart 24-1.	

A, Adult; *C,* child; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *q.i.d.,* four times a day; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; <, less than; >, greater than.

Nursing Diagnoses

- Ineffective breathing pattern related to weak respiratory muscles
- Risk for activity intolerance related to fatigue
- Anxiety related to possible recurrence of myasthenia crisis and dyspnea
- Knowledge deficit related to unfamiliar medications

Planning

- Patient's symptoms of muscle weakness and difficulty breathing and swallowing caused by MG will be eliminated or reduced in 2 to 3 days.

Nursing Interventions

- Monitor effectiveness of drug therapy (acetylcholinesterase inhibitors). Muscle strength should be increased. Both depth and rate of respirations should be assessed and maintained within normal range.
- Administer pyridostigmine IV undiluted at rate of 0.5 mg/min. *Do not add the drug to IV fluids.*
- Observe patient for signs and symptoms of cholinergic crisis caused by overdosing (muscle weakness, increased salivation, sweating, tearing, miosis).
- Have readily available an antidote for cholinergic crisis (atropine sulfate).

Patient Teaching

General

- Teach patient to take drugs as prescribed to avoid recurrence of symptoms.
- Encourage patient to wear a medical identification bracelet or necklace that indicates health problem and drugs taken.

Side Effects

- Advise patient to report to health care provider recurrence of symptoms of MG. Drug therapy may need to be modified.

Diet

- Inform patient to take drug before meals for best drug absorption. If gastric irritation occurs, take drug with food.

Cultural Considerations

- Use simple and clear instructions. Involve family members in teaching about prescriptive therapies and disease process.
- Communicate respect for the patient's and family's culture and beliefs.
- Accommodate cultural values, and assess whether the patient and family are accustomed to not taking all of medication as ordered or using medicines prescribed for other people. Stress that medications need to be taken as prescribed; medications are ordered specifically for each ailment; unused drugs should be discarded; and use of medications by individuals other than the intended may have serious consequences.

Evaluation

- Evaluate effectiveness of the drug therapy to maintain muscle strength.
- Determine the absence of respiratory distress.
- Evaluate correct use of drug by patient.

MULTIPLE SCLEROSIS

MS is an autoimmune disorder that attacks the myelin sheath of nerve fibers in the brain and spinal cord, causing lesions that are called *plaques.* In the United States, MS affects approximately 300,000 persons (age 20 to 40 years), and most are Caucasian women. It is uncommon in African and Asian populations. Onset of MS is usually slow. It is a condition in which there are remissions and exacerbations of multiple symptoms (sensory and cerebellar), such as diplopia, weakness in the extremities, or spasticity. MS is difficult to diagnose because there is no specific diagnostic test, although the McDonald Criteria, revised in 2010, can be used to aid in the diagnosis. Laboratory tests that may suggest MS include elevated immunoglobulin G (IgG) in the cerebrospinal fluid, increased IgG/albumin ratio, and multiple lesions observable through MRI. Scheduling regular treatment protocols to avoid clinical MS attacks is not recommended, because of the side effects of the drugs (e.g., glucocorticoids) used.

There are treatment strategies for three types or phases of MS: the acute attack, remission-exacerbation, and chronic progressive MS. Table 24-2 describes these three phases. Goals for treatment strategies are to decrease the inflammatory process of nerve fibers and improve conduction of demyelinating axons.

SKELETAL MUSCLE RELAXANTS

Muscle relaxants relieve muscular spasms and pain associated with traumatic injuries and spasticity from chronic debilitating disorders (e.g., MS, stroke [cerebrovascular accident], cerebral palsy, head and spinal cord injuries). Spasticity results from increased muscle tone from hyperexcitable neurons caused by increased stimulation from the cerebral neurons or lack of inhibition in the spinal cord or at the skeletal muscles. The centrally acting muscle relaxants depress neuron activity in the spinal cord or brain or enhance neuronal inhibition on the skeletal muscles.

Centrally Acting Muscle Relaxants

The mechanism of action of centrally acting muscle relaxants is not fully known. Centrally acting muscle relaxants are used in cases of spasticity to suppress hyperactive reflex and for muscle spasms that do not respond to antiinflammatory agents, physical therapy, or other forms of therapy. The centrally acting muscle relaxants are described in Table 24-3. Prototype Drug Chart 24-2 gives the drug data for the centrally acting muscle relaxant cyclobenzaprine (Flexeril).

HERBAL ALERT 24-1

Diazepam

Kava kava and valerian may potentiate central nervous system depression.

TABLE 24-2 TREATMENT STRATEGIES FOR THE THREE PHASES OF MULTIPLE SCLEROSIS

PHASE	CHARACTERISTICS	TREATMENT STRATEGIES
Acute attack	Fatigue; motor weakness; optic neuritis	Glucocorticoids Corticotropin (Acthar Gel) 80-120 units IM qd for 2-3 weeks
Remission-exacerbation	Recurrence of clinical MS symptoms; spasticity	Biologic (immune) response modifiers (BRMs); see Chapter 39. Interferon-β (IFN-β) (Betaseron): 25 mcg (8 million international units) subQ every other day. Reduces spasticity and improves muscle movement. Also, interferon β-1a includes Rebif (given subQ in doses of 22 or 44 mcg 3 times per week) and Avonex (given IM in doses of 30 mcg every week), which are used in relapsing forms of MS. Glatiramer acetate (Copaxone) 20 mg subQ once daily; mitoxantrone (Novantrone), an antineoplastic, 12 mg/m^2 IV every 3 months with a lifetime cumulative dose of no more than 140 mg/m^2; and fingolimod (Gilenya), an S1P receptor modulator, 0.5 mg/d PO for adults Teriflumide (Aubagio) given PO 7-14 mg/d Dimethyl fumarate (Tecfidera) given PO 120-240 mg b.i.d.
Chronic progressive	Progressive MS symptoms (using wheelchair)	Immunosuppressant cyclophosphamide (Cytoxan)

b.i.d., Twice a day; *d,* day; *IM,* intramuscular; *IV,* intravenous; *WBC,* white blood cell.

TABLE 24-3 MUSCLE RELAXANTS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Anxiolytics		
diazepam (Valium) CSS IV	A: PO: 2 to 10 mg b.i.d./q.i.d. Older adults: PO: 2 to 2.5 mg qd/b.i.d. Infants >6 months: PO: 1 to 2.5 mg t.i.d./q.i.d. A/C >5 y: IM/IV: 5 to 10 mg q3-4h PRN C <5 y: IM/IV: 1 to 2 mg q3-4h PRN	Diazepam has many uses, one of which is to relieve muscle spasms associated with paraplegia and cerebral palsy. Contraindicated in narrow-angle glaucoma. Pregnancy category: D; PB: 98%; t½: 30 to 60 h
Muscle Relaxants		
Spasticity (Centrally Acting)		
baclofen (Lioresal)	A: PO: Initially 5 mg t.i.d.; increase gradually; *max:* 80 mg/d	For muscle spasms caused by MS and spinal cord injury. Overdose may cause CNS depression. Drowsiness, dizziness, nausea, and hypotension may occur. Pregnancy category: C; PB: 30%; t½: 2.5 to 4 h
tizanidine (Zanaflex)	A: PO: 8 mg q6-8h PRN; *max:* 12 mg single dose or 36 mg/d	To manage spasticity, especially for spinal cord injury and multiple sclerosis. Pregnancy category: C; PB: 30%; t½: 2.5 h
Spasticity (Direct Acting)		
dantrolene sodium (Dantrium)	A: PO: Initially 25 mg/d; increase gradually; *maint:* 100 mg b.i.d./q.i.d. C >5 y: PO: Initially 0.5 mg/kg/d; increase dose gradually by 0.5 mg/kg t.i.d./q.i.d.; *max:* 100 mg q.i.d	For chronic neurologic disorders causing spasms: spinal cord injuries, stroke, MS. Start with low doses and increase every 4 to 7 d. Avoid taking with alcohol or CNS depressants. Pregnancy category: C; PB: 95%; t½: 8 h
Centrally Acting Muscle Relaxants		
carisoprodol (Soma)	A: PO: 250-350 mg t.i.d/q.i.d.	For relaxation of skeletal muscles. Has CNS depressant effects. Avoid taking with alcohol or CNS depressants. Should only be used on short-term basis (2 to 3 weeks).Pregnancy category: C; PB: UK; t½: 2.4 h
chlorzoxazone (Parafon forte DSC)	A: PO: 250 to 500 mg t.i.d./q.i.d.; *max:* 3 g/d	For acute or severe muscle spasms. Not effective for cerebral palsy. Take with food to decrease GI upset. Pregnancy category: C; PB: UK; t½: 1 h
methocarbamol (Robaxin)	A: PO: Initially 1.5 g q.i.d.; *maint:* 4 to 4.5 g/d in 3 to 6 divided doses; *max:* 8 g/d A: IM/IV 1 g q8 h up to 3 consecutive days Not to exceed 3 mL/min IV or inject more than 5 mL IM into each gluteal muscle	For acute muscle spasms; drug used for treatment of tetanus. Has CNS depressant effects (sedation). Avoid taking with alcohol or CNS depressants. Urine may be green, brown, or black. Drowsiness that may occur usually decreases with continued drug use. Pregnancy category: C; PB: UK; t½: 1 to 2 h
metaxalone (Skelaxin)	A: PO: 800 mg t.i.d./q.i.d.; *max:* 3200 mg/d	For acute painful muscle spasticity Pregnancy category: UK; PB: UK; t½: 9 h
orphenadrine citrate (Norflex)	A: PO: 100 mg b.i.d.; *max:* 200 mg/d A: IM/IV: 60 mg q12h; *max:* 120 mg/d	For acute muscle spasm. Can be toxic with a mild overdose. Used in combination with aspirin and caffeine (Norgesic). Pregnancy category: C; PB: <20%; t½: 14 h
Depolarizing Muscle Relaxants (Adjunct to Anesthesia)		
succinylcholine (Anectine)	A/C: IM: 2.5 to 4 mg/kg; *max:* 150 mg; A: IV: 0.3 to 1.1 mg/kg	For surgical skeletal muscle relaxation. Also used in endoscopy and intubation. Pregnancy category: C; PB: UK; t½: UK
Nondepolarizing Muscle Relaxants (Adjunct to Anesthesia)		
pancuronium bromide (Pavulon)	A/C >1 month: IV: 0.04 to 0.1 mg/kg; then 0.01 mg/kg every 30 to 60 min PRN	Used in surgery for relaxation of skeletal muscle (e.g., abdominal wall). Considered to be five times as potent as tubocurarine chloride. Does not cause hypotension or bronchospasm. Pregnancy category: C; PB: 30% to 87%; t½: 2 h
vecuronium (Norcuron)	A/C >10 y: IV: 80 to 100 mcg/kg	For surgical skeletal muscle relaxation. Can be used for patients with asthma, renal disease, or limited cardiac reserve. Given after general anesthesia has been started. Pregnancy category: C; PB: 60% to90%; t½: 1 h

A, Adult; *b.i.d.,* twice a day; *C,* child; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *MS,* multiple sclerosis; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *q.i.d.,* four times a day; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *y,* year; >, greater than; <, less than.

PROTOTYPE DRUG CHART 24-2

Cyclobenzaprine

Drug Class Centrally acting muscle relaxant Trade Name: Flexeril Pregnancy Category: B	**Dosage** A: P.O. 5-10 mg; *max:* 30 mg/d
Contraindications Acute myocardial infarction, AV blocks, bundle-branch block, cardiac arrhythmias, heart failure, hyperthyroidism, paralytic ileus, concurrent use of monoamine oxidase inhibitors or within 14 days after discontinuation. Caution: Seizure disorder, alcohol, CNS depressants, glaucoma, prostatic hypertrophy, urinary retention, hepatic dysfunction, breastfeeding	**Drug-Lab-Food Interactions** Drug: Increased CNS depression with alcohol, kava kava, valerian, barbiturates, tricyclic antidepressants, and other CNS depressants. Take with food or milk to decrease GI upset.
Pharmacokinetics Absorption: PO: Well absorbed Distribution: PB: 93% Metabolism: $t\frac{1}{2}$: 8-37 h Excretion: In urine	**Pharmacodynamics** PO: Onset: 1 h Peak: 3-8 h Duration: 12-24 h
Therapeutic Effects/Uses For short-term treatment of muscle spasms. Mode of Action: Relieves muscle spasms through a central action, possibly at the brain stem level.	
Side Effects Anticholinergic effects (blurred vision, constipation, dry mouth, tachycardia, urinary retention); drowsiness; dizziness; headache; fever; abdominal pain; vomiting; diarrhea; flatulence; erectile dysfunction	**Adverse Reactions** Allergic reactions, angioedema, myocardial infarction, seizures, ileus

A, Adult; *CNS,* central nervous system; *d,* day; *h,* hour; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; $t\frac{1}{2}$, half-life; *UK,* unknown; >, greater than.

Spasticity

Skeletal muscle spasticity is muscular hyperactivity that causes contraction of the muscles, resulting in pain and limited mobility. Centrally acting muscle relaxants act on the spinal cord. Examples of centrally acting muscle relaxants used to treat spasticity are baclofen (Lioresal), dantroene (Dantrium), and tizanidine (Zanaflex). Diazepam (Valium), a benzodiazepine, has also been effective for treating spasticity.

SAFETY: Preventing Medication Errors

Do not confuse . . .

- **baclofen** (skeletal muscle relaxant) with **Bactroban** (topical antibacterial) or **Beclovent** (corticosteroid inhalant).

Muscle Spasms

Various centrally acting muscle relaxants are used for muscle spasm to decrease pain and increase range of motion. They have a sedative effect and should not be taken concurrently with CNS depressants such as barbiturates, narcotics, and alcohol. These agents, with the exception of cyclobenzaprine, can cause drug dependence. In addition, dizziness and drowsiness are common side effects. Examples of this group of centrally acting muscle relaxants are carisoprodol (Soma), chlorzoxazone (Parafon forte DSC), cyclobenzaprine (Flexeril), metaxalone (Skelaxin), methocarbamol (Robaxin), and orphenadrine citrate (Norflex).

Pharmacokinetics Cyclobenzaprine is well absorbed from the GI tract, and its half-life is moderate. The protein-binding percentage for cyclobenzaprine is 93%. Cyclobenzaprine is metabolized in the liver and excreted in urine.

Pharmacodynamics Cyclobenzaprine alleviates muscle spasm associated with acute painful musculoskeletal conditions. When cyclobenzaprine is taken with alcohol, kava kava, valerian, sedative-hypnotics, barbiturates, or tricyclic antidepressants (TCAs), increased central nervous system (CNS) depression occurs. The onset of action, peak concentration time, and duration of action for cyclobenzaprine is short.

Side Effects and Adverse Reactions

The side effects from centrally acting muscle relaxants include drowsiness, dizziness, lightheadedness, headaches, and occasional GI sensitivity (e.g., nausea, vomiting, abdominal distress). Cyclobenzaprine and orphenadrine have anticholinergic effects.

Nursing Process
Patient-Centered Collaborative Care

Muscle Relaxant: Cyclobenzaprine

Assessment

- Collect medical history. Cyclobenzaprine is contraindicated if patient has cardiovascular disorders,

hyperthyroidism, or hepatic impairment, or is taking concurrent MAOIs.
- Obtain baseline vital signs for future comparison.
- Secure patient's health history to identify the cause of muscle spasm and determine whether it is acute or chronic.
- Gather a drug history. Report if a drug-drug interaction is probable.
- Note if there is a history of narrow-angle glaucoma or MG. Cyclobenzaprine and orphenadrine are contraindicated with these health problems.

Nursing Diagnoses
- Impaired physical mobility related to dizziness and hyperactive reflexes
- Activity intolerance related to drowsiness and hyperactive reflexes

Planning
- Patient will be free of muscular pain within 1 week.

Nursing Interventions
- Monitor serum liver enzyme levels of patients taking dantrolene and carisoprodol. Report elevated levels of liver enzymes such as alkaline phosphatase (ALP), alanine aminotransferase (ALT), and gamma-glutamyl transferase (GGT).
- Record vital signs. Report abnormal results.
- Observe for CNS side effects (e.g., dizziness).

Patient Teaching
General
- Teach patient that the muscle relaxant should not be abruptly stopped. Drug should be tapered over 1 week to avoid rebound spasms.
- Advise patient not to drive or operate dangerous machinery when taking muscle relaxants. These drugs have a sedative effect and can cause drowsiness.
- Inform patient that most of the centrally acting muscle relaxants for acute spasms are usually taken for no longer than 3 weeks.
- Teach patient to avoid alcohol and CNS depressants. If muscle relaxants are taken with these drugs, CNS depression may be intensified.
- Advise patient that these drugs must be used cautiously for pregnant or nursing patients. Check with health care provider.

Side Effects
- Encourage patient to report side effects of the muscle relaxant: nausea, vomiting, dizziness, fainting, headache, and diplopia. Dizziness and fainting are most likely caused by orthostatic (postural) hypotension.

Diet
- Advise patient to take muscle relaxants with food to decrease gastrointestinal upset.

Cultural Considerations
- Use both hands to show respect when offering a prescription, instructions, or pamphlets to Asians and Pacific Islanders.
- Demonstrate respect by addressing patient formally until told otherwise, and do not ask private questions in public.

Evaluation
- Evaluate effectiveness of muscle relaxant to determine whether patient's muscular pain or spasms have decreased or disappeared.

National Multiple Sclerosis Society: *www.nationalmssociety.org/index.aspx*

CRITICAL THINKING CASE STUDY

FR, a 29-year-old woman, was diagnosed with myasthenia gravis (MG) 2 years ago. She is receiving pyridostigmine (Mestinon) 120 mg t.i.d. Last evening, FR was involved in an automobile accident. She was taken to the emergency department unconscious and missed two evening doses of pyridostigmine.

1. How does pyridostigmine alleviate the symptoms of MG?
2. What are the potential side effects and adverse effects of pyridostigmine?
3. What problems are likely to develop following delayed pyridostigmine dosing?

FR is scheduled for surgery to repair a fractured right femur suffered in the accident. During surgery, FR develops bradycardia.

1. What medications may lead to drug interactions with pyridostigmine?
2. What problems may develop from pyridostigmine overdosing?
3. What are the similarities between myasthenia crisis and cholinergic crisis?

NCLEX STUDY QUESTIONS

1. When the nurse explains the pathophysiology of myasthenia gravis to a patient, which is the best explanation?
   - **a.** Degeneration of cholinergic neurons and a deficit in acetylcholine lead to neuritic plaques and neurofibrillary tangles.
   - **b.** Decreased amount of acetylcholine to cholinergic receptors produces weak muscles and reduced nerve impulses.
   - **c.** Myelin sheaths of nerve fibers in brain and spinal cord develop lesions or plaques.
   - **d.** Imbalance of dopamine and acetylcholine leads to degeneration of neurons in midbrain and extrapyramidal motor tracts.
2. The nurse is teaching a patient recently diagnosed with multiple sclerosis (MS) about the disease. Which statement is not correct concerning multiple sclerosis?
   - **a.** The disease has periods of exacerbations and remissions.
   - **b.** Goals of treatment are to decrease the inflammation in the nervous system.
   - **c.** Patients with MS should avoid calcium channel blockers.
   - **d.** A tapering course of glucocorticoids can be used to treat an acute attack.
3. A patient has spasticity following a spinal cord injury. The nurse anticipates that which drug will be prescribed to treat the patient's spasticity?
   - **a.** tacrine (Cognex)
   - **b.** ropinirole (Requip)
   - **c.** cyclobenzaprine (Flexeril)
   - **d.** pyridostigmine (Mestinon)
4. The nurse anticipates that the health care provider will prescribe which medication to treat a patient with multiple sclerosis in the chronic progressive phase?
   - **a.** ambenonium (Mytelase)
   - **b.** interferon β-1a (Avonex, Rebif)
   - **c.** glatiramer acetate (Copaxone)
   - **d.** cyclophosphamide (Cytoxan)
5. The nurse is providing medication instructions to a patient with acute muscle spasms who has been prescribed cyclobenzaprine (Flexeril). Which statement indicates to the nurse that the patient understands the instructions?
   - **a.** "I plan to take this medication with a glass of milk."
   - **b.** "Cyclobenzaprine should be taken once daily at bedtime."
   - **c.** "I will only drink one glass of wine per day."
   - **d.** "I will not be able to drink grapefruit juice while taking this drug."
6. Which instructions will the nurse include in the teaching plan for a patient who is taking pyridostigmine (Mestinon)? (Select all that apply.)
   - **a.** Pyridostigmine bromide must be taken on time.
   - **b.** Take two times per day.
   - **c.** Underdosing can result in myasthenic crisis.
   - **d.** Overdosing can result in cholinergic crisis.
   - **e.** Report the adverse effect of tachycardia to the health care provider.
7. A patient is beginning to take cyclobenzaprine (Flexeril) for treatment of acute back spasms. Which interventions will the nurse include in the care of this patient? (Select all that apply.)
   - **a.** Advise the patient to take this drug on an empty stomach.
   - **b.** Inform the patient that muscular pain is usually relieved within 1 week.
   - **c.** Tell the patient to report dizziness and double vision to the health care provider.
   - **d.** Advise the patient to avoid alcohol.
   - **e.** Taking narcotics at the same time can cause serious side effects.
8. The nurse is reviewing a patient's medication history for a patient who has just been prescribed cyclobenzaprine (Flexeril) for treatment of back spasms. The nurse plans to contact the health care provider if the patient is taking which medication?
   - **a.** atorvastatin calcium (Lipitor)
   - **b.** conjugated estrogen (Premarin)
   - **c.** phenelzine (Nardil)
   - **d.** penicillin G procaine (Crysticillin, Wycillin)
9. The nurse is caring for a patient who is diagnosed with myasthenia gravis. The patient is experiencing muscle weakness, dyspnea, bradycardia, and diaphoresis. The nurse anticipates that the health care provider will order which medication to distinguish between myasthenia crisis and cholinergic crisis?
   - **a.** adrenocorticotropic hormone (ACTH) (H.P. Acthar)
   - **b.** diazepam (Valium)
   - **c.** edrophonium chloride (Tensilon)
   - **d.** mitoxantrone (Novantrone)

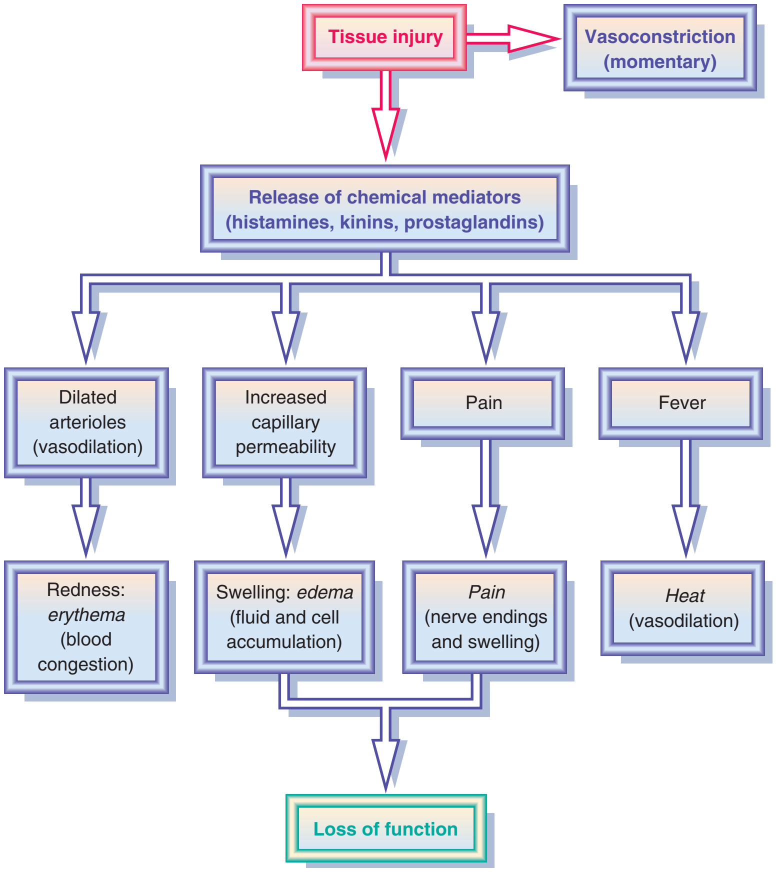
UNIT VII

Pain and Inflammation Management Agents

Inflammation is a reaction to tissue injury caused by the release of chemical mediators that trigger both a vascular response and the migration of fluid and cells (leukocytes, or white blood cells) to the injured site. The chemical mediators are (1) histamines, (2) kinins, and (3) prostaglandins. Histamine, the first mediator in the inflammatory process, causes dilation of the arterioles and increases capillary permeability, allowing fluid to leave the capillaries and flow into the injured area. Kinins, such as bradykinin, also increase capillary permeability and the sensation of pain. Prostaglandins are released, causing an increase in vasodilation, capillary permeability, pain, and fever. The antiinflammatory drugs, such as nonsteroidal antiinflammatory drugs (NSAIDs) and steroids (cortisone preparations), inhibit chemical mediators, thus decreasing the inflammatory process. Figure VII-1 illustrates the process of chemical mediators acting on injured tissues. The five responses to tissue injury are called the cardinal signs of inflammation: redness, swelling, pain, heat, and loss of function.

Inflammation may or may not be the result of an infection; only a small percentage of inflammations are caused by infections. Other causes of inflammation include trauma, surgical interventions, extreme heat or cold, and caustic chemical agents. Antiinflammatory drugs reduce fluid migration and pain, lessening loss of function and increasing the patient's mobility and comfort.



Tissue injury
Vasoconstriction (momentary)
Release of chemical mediators (histamines, kinins, prostaglandins)
Dilated arterioles (vasodilation)
Increased capillary permeability
Pain
Fever
Redness: *erythema* (blood congestion)
Swelling: *edema* (fluid and cell accumulation)
Pain (nerve endings and swelling)
Heat (vasodilation)
Loss of function

FIGURE VII–1 Chemical mediator response to tissue injury.

OBJECTIVES

- Explain the pathophysiologic basis of five cardinal signs of inflammation.
- Compare the action of various nonsteroidal antiinflammatory drugs (NSAIDs).
- Explain the use of disease-modifying antirheumatic drugs (DMARDs).
- Differentiate between the side effects and adverse reactions of NSAIDs and DMARDs.
- Correlate the nursing processes associated with NSAIDs and corticosteroids, including patient teaching.
- Apply the nursing process to the patient taking DMARDs.
- Compare the action of various antigout medications.

OUTLINE

Pathophysiology
Antiinflammatory Agents
Nonsteroidal Antiinflammatory Drugs
  Salicylates
  Nursing Process: Patient-Centered Collaborative Care: Salicylate: Aspirin
  Para-Chlorobenzoic Acid
  Phenylacetic Acid Derivatives
  Propionic Acid Derivatives
  Fenamates
  Oxicams
  Nursing Process: Patient-Centered Collaborative Care: Nonsteroidal Antiinflammatory Drug: Ibuprofen
  Selective COX-2 Inhibitors (Second-Generation NSAIDs)
  Use of NSAIDs in Older Adults
Corticosteroids
Disease-Modifying Antirheumatic Drugs
  Immunosuppressive Agents
  Immunomodulators
  Nursing Process: Patient-Centered Collaborative Care: Infliximab (Remicade)
  Antimalarials
Antigout Drugs
  Antiinflammatory Gout Drug: Colchicine
  Uric Acid Inhibitor
  Uricosurics
  Nursing Process: Patient-Centered Collaborative Care: Antigout: Allopurinol

Inflammation is a response to tissue injury and infection. When the inflammatory process occurs, a vascular reaction takes place in which fluid, elements of blood, leukocytes (white blood cells [WBCs]), and chemical mediators accumulate at the injured tissue or infection site. The process of inflammation is a protective mechanism in which the body attempts to neutralize and destroy harmful agents at the site of injury and to establish conditions for tissue repair.

Although there is a relationship between inflammation and infection, these terms should *not* be used interchangeably. **Infection** is caused by microorganisms and results in inflammation, but *not* all inflammations are caused by infections.

PATHOPHYSIOLOGY

The five characteristics of inflammation, called *the cardinal signs of inflammation,* are redness, swelling (edema), heat, pain, and loss of function. Table 25-1 gives the description and explanation of the cardinal signs of inflammation. The two phases of inflammation are the *vascular phase,* which occurs 10 to 15 minutes after an injury, and the *delayed phase.* The vascular phase is associated with vasodilation and increased capillary permeability, during which blood substances and fluid leave the plasma and go to the injured site. The delayed phase occurs when leukocytes infiltrate the inflamed tissue.

Various chemical mediators are released during the inflammation process. Prostaglandins that have been isolated from the exudate at inflammatory sites are among them. **Prostaglandins** (chemical mediators) have many effects: vasodilation, relaxation of smooth muscle, increased capillary permeability, and sensitization of nerve cells to pain.

TABLE 25-1 CARDINAL SIGNS OF INFLAMMATION

SIGNS	DESCRIPTION AND EXPLANATION
Erythema (redness)	Redness occurs in the first phase of inflammation. Blood accumulates in the area of tissue injury because of the release of the body's chemical mediators (kinins, prostaglandins, and histamine). Histamine dilates the arterioles.
Edema (swelling)	Swelling is the second phase of inflammation. Plasma leaks into the interstitial tissue at the injury site. Kinins dilate the arterioles, increasing capillary permeability.
Heat	Heat at the inflammatory site can be caused by increased blood accumulation and may result from pyrogens (substances that produce fever) that interfere with the temperature-regulating center in the hypothalamus.
Pain	Pain is caused by tissue swelling and the release of chemical mediators.
Loss of function	Function is lost because of the accumulation of fluid at the tissue injury site and because of pain, which decreases mobility at the affected area.

Cyclooxygenase (COX) is the enzyme responsible for converting arachidonic acid into prostaglandins and their products. This synthesis of prostaglandins causes inflammation and pain at a tissue injury site. There are two enzyme forms of cyclooxygenase: COX-1 and COX-2. COX-1 protects the stomach lining and regulates blood platelets, and COX-2 triggers inflammation and pain.

ANTIINFLAMMATORY AGENTS

Drugs such as aspirin inhibit the biosynthesis of prostaglandin and are therefore called *prostaglandin inhibitors.* Because prostaglandin inhibitors affect the inflammatory process, they are more commonly called *antiinflammatory agents.*

Antiinflammatory agents also relieve pain (analgesic), reduce elevated body temperature (antipyretic), and inhibit platelet aggregation (anticoagulant). Aspirin is the oldest antiinflammatory drug, but it was first used for its analgesic and antipyretic properties. As a result of searching for a more effective drug with fewer side effects, many other antiinflammatory agents, or prostaglandin inhibitors, have been discovered. Although these drugs have potent antiinflammatory effects that mimic the effects of corticosteroids (cortisone), they are *not* chemically related to corticosteroids and therefore are called **nonsteroidal antiinflammatory drugs (NSAIDs).** Most NSAIDs are used to decrease inflammation and pain for patients who have some type of arthritic condition.

NONSTEROIDAL ANTIINFLAMMATORY DRUGS

NSAIDs are aspirin and aspirin-like drugs that inhibit the enzyme COX, which is needed for the biosynthesis of prostaglandins. Chapters 26 and 45 present expanded discussions of NSAIDs in their roles as analgesics and anticoagulants, respectively. These drugs may be called *prostaglandin inhibitors* with varying degrees of analgesic and antipyretic effects, but they are used primarily as antiinflammatory agents to relieve inflammation and pain. Their antipyretic effect is less than their antiinflammatory effect. With several exceptions, NSAID preparations are not suggested for use in alleviating mild headaches and mildly elevated temperature. Preferred drugs for headaches and fever are aspirin, acetaminophen, and ibuprofen (given to children and adults with high fever). NSAIDs are more appropriate for reducing swelling, pain, and stiffness in joints.

NSAIDs cost more than aspirin. Other than aspirin, the only NSAIDs that can be purchased over-the-counter (OTC) are ibuprofen (Motrin, Advil) and naproxen (Aleve). Ibuprofen is also available in generic form in 200-mg tablets or capsules. All other NSAIDs require a prescription. Examples of prescription products on the market that contain NSAID contents alone or in combination include Anaprox, Celebrex, Clinoril, Daypro, Equagesic, Naprosyn, Percodan, Relafen, Soma Compound, Talwin, and Toradol. If a patient can take aspirin for the inflammatory process without gastrointestinal (GI) upset, salicylate products are usually recommended.

There are seven groups of NSAIDs:

1. Salicylates
2. *Para*-chlorobenzoic acid derivatives, or indoles
3. Phenylacetic acids
4. Propionic acid derivatives
5. Fenamates
6. Oxicams
7. Selective COX-2 inhibitors

The first six NSAID groups on the list are known as *first-generation NSAIDs*, and the COX-2 inhibitors are called *second-generation NSAIDs*.

Table 25-2 provides dosage information and considerations for use for the most commonly used NSAIDs. The half-lives of NSAIDs differ greatly—some have a short half-life, and others have a moderate to long half-life with a general range of 8 to 24 hours. Aspirin should not be taken with an NSAID because of the side effects. In addition, combined therapy does not increase effectiveness.

Salicylates

Aspirin comes from the family of salicylates derived from salicylic acid. Aspirin is also called *acetylsalicylic acid (ASA)* after the acetyl group used in the composition of aspirin. The abbreviation frequently used for aspirin is ASA.

TABLE 25-2 ANTIINFLAMMATORY AGENTS: NONSTEROIDAL

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
First-Generation NSAIDs		
Salicylates		
aspirin (ASA, Bayer, Ecotrin)	See Prototype Drug Chart 25-1.	
diflunisal (Dolobid)	A: PO: 250-500 mg b.i.d.; *max:* 1500 mg/d	Relief of mild to moderate pain; used to treat osteoarthritis and rheumatoid arthritis. Acts by inhibiting prostaglandin synthesis. Avoid if hypersensitive to aspirin. Do not use during third trimester of pregnancy. Pregnancy category: C; PB: 99%; t½: 8-12 h
Salicylate Derivatives		
olsalazine sodium (Dipentum)	A: PO: 500 mg q12h; may increase dose every 2-4 wk; *max:* 3 g/d in divided doses	For inflammatory bowel disease, especially ulcerative colitis. Excreted mainly in feces as 5-ASA. Pregnancy category: C; PB: 99%; t½: 5-10 h
sulfasalazine (Azulfidine)	A: PO: 0.5-1 g/d initially, then 2 g/d in divided doses; *max:* 3 g/d C >6 y: PO: 30-50 mg/kg/d in 4 divided doses; *max:* 2 g/d	For ulcerative colitis and rheumatoid arthritis. Avoid if allergic to sulfonamides or aspirin. Pregnancy category: B; PB: 99%; t½: 5-10 h
Para-Chlorobenzoic Acid (Indoles)		
indomethacin (Indocin)	A: PO: 75-150 mg/d in 3-4 divided doses with food for 7-14 d; *max:* 200 mg/d; SR: 75 mg daily/b.i.d.; *max:* 150 mg/d	For moderate to severe arthritic conditions. GI upset and ulceration are common. Take with food. Avoid if allergic to aspirin. Pregnancy category: C; PB: 99%; t½: 4.5 h
sulindac (Clinoril)	A: PO: 150-200 mg b.i.d.; *max:* 400 mg/d	For acute and chronic arthritis, bursitis, and tendinitis. Not as potent as indomethacin. Take with food. Pregnancy category: C; PB: 93%; t½: 7.8 h
tolmetin	A: PO: Initially: 400 mg t.i.d.; *maint:* 600-1800 mg/d in divided doses; *max:* 1.8 g/d C >2 y: PO: 20 mg/kg/d in divided doses; *max:* 30 mg/kg/d	For acute and chronic arthritis, including juvenile rheumatoid arthritis. Less potent than indomethacin; more effective than aspirin. Take with food. Pregnancy category: C (D, third trimester); PB: 90%-99%; t½: 1-2 h
Phenylacetic Acid		
diclofenac sodium (Voltaren XR)	A: PO: 25-50 mg t.i.d./q.i.d.; SR: 100 mg/d	For rheumatoid arthritis, osteoarthritis, and spondylitis. Also for acute gout, juvenile rheumatoid arthritis, bursitis, and tendinitis. Take with food to avoid GI upset. Pregnancy category: C (D, third trimester); PB: 90%-99%; t½: 2 h
etodolac (Lodine)	A: PO: 600-1000 mg/d in 2-4 divided doses PRN; *max:* 1200 mg/d	For acute pain, rheumatoid arthritis, and osteoarthritis. Take with food or antacid to avoid GI upset. Pregnancy category: C (D, third trimester); PR: 99%; t½: 6-7 h
ketorolac tromethamine (Toradol)	A: PO: 20 mg q6h PRN; *max:* 40 mg/d IM/IV: 30 mg q6h PRN; *max:* 120 mg/d Older adults: PO: 5-10 mg q6h PRN; *max:* 40 mg/d IM/IV: 15 mg q6h PRN; *max:* 60 mg/d	First injectable NSAID. For short-term pain management of 5 days or less. Also available for ophthalmic use to relieve itching caused by allergic conjunctivitis. Pregnancy category: C (D, third trimester); PB: 99%; t½: 4-6 h

TABLE 25-2 ANTIINFLAMMATORY AGENTS: NONSTEROIDAL—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Propionic Acid		
fenoprofen calcium (Nalfon)	A: PO: 300-600 mg t.i.d./q.i.d.; *max:* 3200 mg/d	For mild to moderate pain. Also for arthritic conditions. Most effective after 2-3 wk of therapy. Take with food. Pregnancy category: C (D, third trimester); PB: 90%-99%; t½: 3 h
flurbiprofen sodium (Ansaid)	A: PO: 200-300 mg/d in 2-4 divided doses; *max:* 300 mg/d	For acute and chronic arthritis. Take with food. Pregnancy category: C (D, third trimester); PB: 99%; t½: 5 h
ibuprofen (Motrin, Advil)	See Prototype Drug Chart 25-2.	
ketoprofen (Nexcede)	Arthritis: A: PO: Initially 50 mg q.i.d. or 75 mg t.i.d.; *max:* 300 mg/d SR: A: PO: 200 mg q.d.; *max:* 200 mg/d SR: Older adult: PO: 100-150 mg/d; *max:* 200 mg/d Mild to moderate pain: A: PO: 12.5-50 mg q6-8h PRN; *max:* 300 mg/d	Relief of mild to moderate pain and acute and chronic arthritis. Take with food or 8 ounces of water to avoid GI upset. Pregnancy category: C (D, third trimester); PB: 99%; t½: 2-4 h
naproxen (Naprosyn, Aleve)	A: PO: 250-500 mg b.i.d.; *max:* 1500 mg/d C >2y: PO: 5-10 mg/kg q12h; *max:* 1000 mg/d	Relief of mild to moderate pain. Also for arthritic, gout, and bursitis conditions, and dysmenorrhea. OTC drug: Aleve. Take with food or with a full glass of water. Pregnancy category: C (D, third trimester); PB: 99%; t½: 12-17 h
oxaprozin (Daypro)	A: PO: 600-1200 mg/d; *max:* 1800 mg/d in divided doses	Treatment of acute and chronic arthritis. Take with food to avoid GI upset.. Pregnancy category: C (D, third trimester); PB: 99%; t½: 40 h
Anthranilic Acids (Fenamates)		
meclofenamate	A: PO: 200-400 mg/d in 3-4 divided doses; *max:* 400 mg/d	For acute and chronic arthritis. GI symptoms can be severe. Used when other NSAIDs are not effective. Take with food to avoid GI upset. Pregnancy category: C (D, at term); PB: 99%; t½: 2 h
mefenamic acid (Ponstel)	A: PO: Initially: 500 mg; then 250 mg q6h PRN; *max:* 1250 mg/d	For acute and chronic arthritis. Diarrhea is a common problem. Usually discontinued after 7 days. Pregnancy category: C (D, third trimester); PB: 90%; t½: 2 h
Oxicams		
piroxicam (Feldene)	A: PO: 10-20 mg q.d.; *max:* 20 mg/d	For arthritic conditions. Long half-life; effective at 2 weeks. GI upset may occur. Pregnancy category: C (D, third trimester); PB: 99%; t½: 50 h
meloxicam (Mobic)	A: PO: 7.5-15 mg/d; *max:* 15 mg/d	For osteoarthritis. Some COX-2 selectivity. Pregnancy category: C (first and second trimester), D (third trimester); PB: 99%; t½: 15-20 h
Naphthylalkanones		
nabumetone (Relafen)	A: PO: 500-1000 mg q.d./b.i.d.; *max:* 2000 mg/d	For chronic inflammation and pain, especially for arthritic conditions such as rheumatoid arthritis and osteoarthritis. Inhibits cyclooxygenase, particularly COX-2 more than COX-1; fewer GI problems. Pregnancy category: C (D, third trimester); PB: 99%; t½: 24 h
COX-2 Inhibitors (Second-Generation NSAIDs)		
celecoxib (Celebrex)	See Prototype Drug Chart 25-3.

Aspirin was developed in 1899 by Adolph Bayer, making it the oldest antiinflammatory agent. It was the most frequently used antiinflammatory agent before the introduction of ibuprofen. Aspirin is a prostaglandin inhibitor that decreases the inflammatory process. It is also considered an antiplatelet drug for patients with cardiac or cerebrovascular disorders; aspirin decreases platelet aggregation, and thus blood clotting is decreased. Because high doses of aspirin are usually needed to relieve inflammation, gastric distress is a common problem. In such cases, enteric-coated (EC) tablets

*Aspirin is only one of the NSAIDs.

FIGURE 25–1 Uses of COX-1 and COX-2 inhibitors.

may be used. Aspirin should *not* be taken with other NSAIDs because it decreases the blood level and effectiveness of NSAIDs.

Aspirin and other NSAIDs relieve pain by inhibiting the enzyme COX, which is needed for the biosynthesis of prostaglandins. There are two enzyme forms of cyclooxygenase, symbolized as COX-1 and COX-2 (Figure 25-1). COX-1 protects the stomach lining and regulates blood platelets, promoting blood clotting. COX-2 triggers pain and inflammation at the injured site. Usually NSAIDs inhibit or block both COX-1 and COX-2. Inhibition of COX-1 produces the desirable effect of decreasing platelet aggregation, but the undesirable effect of decreasing protection to the stomach lining. Stomach bleeding and ulcers may occur with aspirin and NSAID agents. When COX-2 is inhibited, pain and fever are reduced and inflammation is suppressed, but COX-2 inhibitors do not cause gastric ulceration and have no effect on platelet function.

New NSAIDs, called **COX-2 inhibitors,** block only COX-2 and not COX-1. These drugs leave protection for the stomach lining intact (no gastric bleeding and ulcers), but still deliver relief for pain and inflammation.

A COX-2 inhibitor approved by the U.S. Food and Drug Administration (FDA) is celecoxib (Celebrex). Drugs similar to COX-2 inhibitors include meloxicam (Mobic) and nabumetone (Relafen), which allow some stomach protection. Patients at risk for stroke or heart attack who take aspirin to prevent blood clotting (decrease platelet aggregation) would not benefit from COX-2 inhibitors. If the COX-1 enzyme was not blocked, increased blood clotting would remain even though the stomach lining is protected.

Many researchers believe that COX-2 inhibitors may prevent some types of cancer (e.g., colon cancer). Fruits and vegetables block COX-2 enzyme naturally, protecting the colon from malignant growths.

Pharmacokinetics Aspirin is well absorbed from the GI tract (Prototype Drug Chart 25-1). It can cause GI upset, so it should be taken with water, milk, or food. The EC or buffered form can decrease gastric distress. EC tablets should not be crushed or broken.

Aspirin has a short half-life. It should not be taken during the last trimester of pregnancy, because it could cause premature closure of the ductus arteriosus in the fetus. Aspirin should not be taken by children with flu symptoms, because it may cause the potentially fatal Reye syndrome.

Pharmacodynamics Aspirin, like other NSAIDs, inhibits prostaglandin synthesis by inhibiting COX-1 and COX-2; thus it decreases inflammation and pain. The onset of action for aspirin is within 30 minutes. It peaks in 1 to 2 hours, and the duration of action is an average of 4 to 6 hours. The action for the rectal preparation of aspirin can be erratic because of blood supply and fecal material in the rectum; it may take a week or longer for a therapeutic antiinflammatory effect.

Hypersensitivity to Salicylate Products

Patients may be hypersensitive to aspirin. Tinnitus (ringing in the ears), vertigo (dizziness), and bronchospasm—especially in asthmatic patients—are symptoms of aspirin overdose or hypersensitivity to aspirin. Patients should not take diflunisal if they are hypersensitive to aspirin. Diflunisal is a derivative of salicylic acid, although it is not converted to salicylic acid in the body.

Salicylates are present in numerous foods (e.g., prunes, raisins, licorice) and in spices (e.g., curry powder, paprika).

Nursing Process

Patient-Centered Collaborative Care

Salicylate: Aspirin

Assessment

- Determine a medical history. Ask patient if there is any history of gastric upset, gastric bleeding, or liver disease. Aspirin can cause gastric irritation. It prolongs bleeding time by inhibiting platelet aggregation.
- Obtain a drug history. Report if a drug-drug interaction is probable.

Nursing Diagnoses

- Risk for injury related to vertigo
- Chronic pain related to tissue swelling of rheumatoid arthritis

Planning

- The patient's pain will be reduced within 12 to 24 hours.
- The patient's inflammation will be reduced within 1 week.

PROTOTYPE DRUG CHART 25-1

Aspirin

Drug Class

Analgesic: antiinflammatory drug

Trade Names: ASA, Bayer, Ecotrin, 🍁 Astrin

Pregnancy Category: D

Dosage

Analgesic:
A: PO: 325-650 mg q4h PRN; *max:* 4 g/d
C: PO: 10-15 mg/kg in 4 to 6 divided doses; *max:* 4 g/d
TIA and thromboembolic condition:
A: PO: 81-325 mg/d
Arthritis:
A: PO: 3 g/d in divided doses
TDM: 15-30 mg/dL; 150 to 300 mcg/mL

Contraindications

Hypersensitivity to salicylates or NSAIDs, flu or virus symptoms in children, anticoagulant therapy, GI bleeding, bone marrow suppression, third trimester of pregnancy

Caution: Renal or hepatic disorders gout, alcoholism

Drug-Lab-Food Interactions

Drug: Increase risk of bleeding with anticoagulants and other NSAIDs; increase risk of hypoglycemia with oral hypoglycemic drugs; increase ulcerogenic effect with glucocorticoids

Lab: Decrease cholesterol and potassium, T3, T4 levels; increase PT, bleeding time, uric acid

Pharmacokinetics

Absorption: PO: 80%-100%
Distribution: PB: 80%-90%, crosses placenta
Metabolism: $t\frac{1}{2}$: 2-3 h (low dose); 15-20 h (high dose)
Excretion: 50% in urine

Pharmacodynamics

PO: Onset: 15-30 min
Peak: 1-2 h
Duration: 4-6 h
PR: Onset: 1-2 h
Peak: 3-5 h
Duration: 4-7 h

Therapeutic Effects/Uses

To reduce pain and inflammatory symptoms; to decrease body temperature; to inhibit platelet aggregation

Mode of Action: Inhibition of prostaglandin synthesis, inhibition of hypothalamic heat-regulator center

Side Effects

Anorexia, nausea, vomiting, diarrhea, dizziness, confusion, hearing loss, heartburn, rash, abdominal pain, drowsiness

Adverse Reactions

Tinnitus, urticaria, ulceration, GI bleeding

Life-threatening: Agranulocytosis, hemolytic anemia, bronchospasm, anaphylaxis, thrombocytopenia, Reye's syndrome, hepatotoxicity, leukopenia

A, Adult; *ASA,* acetylsalicylic acid; *b.i.d.,* two times a day; *C,* child; *d,* day; *h,* hour; *max,* maximum; *min,* minute; *NSAIDs,* nonsteroidal antiinflammatory drugs; *PB,* protein binding; *PO,* by mouth; *PR,* per rectum; *PRN,* as necessary; *PT,* prothrombin time; $t\frac{1}{2}$, half-life; *TDM,* therapeutic drug monitoring; *TIA,* transient ischemic attack; 🍁, Canadian drug name.

Nursing Interventions

- Monitor serum salicylate (aspirin) level when patient takes high doses of aspirin for chronic conditions such as arthritis. Normal therapeutic range is 15 to 30 mg/dL. Mild toxicity occurs at serum level of >30 mg/dL, and severe toxicity occurs at >50 mg/dL.
- Observe patient for signs of bleeding such as dark (tarry) stools, bleeding gums, petechiae (round red spots), ecchymosis (excessive bruising), and purpura (large red spots) when patient takes high doses of aspirin.

Patient Teaching

General

- Advise patient not to take aspirin with alcohol or with drugs that are highly protein-bound, such as the anticoagulant warfarin (Coumadin). Aspirin displaces drugs like warfarin from the protein-binding site, causing increased anticoagulant levels.
- Suggest that patient inform the dentist before a dental visit if taking high doses of aspirin.
- Instruct patient to discontinue aspirin 3 to 7 days before surgery to reduce risk of bleeding (with the health care provider's approval).
- Keep aspirin bottle out of reach of children.
- Educate parent to call poison control center immediately if a child has taken a large or unknown amount of aspirin (or acetaminophen).
- Warn patient not to administer aspirin for virus or flu symptoms in children. Reye's syndrome (vomiting, lethargy, delirium, and coma) has been linked with aspirin and viral infections. Acetaminophen is usually prescribed for cold and flu symptoms.
- Inform patient that aspirin tablets can cause GI distress.

- Inform patient with dysmenorrhea to take acetaminophen instead of aspirin 2 days before and during the first 2 days of the menstrual period.

Side Effects

- Direct patient to report side effects such as drowsiness, tinnitus (ringing in the ears), headaches, flushing, dizziness, GI symptoms (bleeding, heartburn), visual changes, and seizures.

Diet

- Instruct patient to take aspirin (also ibuprofen) with food, at mealtime, or with plenty of fluids. EC aspirin helps prevent GI disturbance.

Cultural Considerations

- Do not misunderstand loud voice volume as necessarily reflecting anger or agitation; patients may be merely expressing their thoughts in a dynamic manner.

Evaluation

- Evaluate the effectiveness of aspirin in relieving pain. If pain persists, another analgesic such as ibuprofen may be prescribed.
- Determine whether patient has any side effects to aspirin.

Para-Chlorobenzoic Acid

One of the first NSAIDs introduced was indomethacin (Indocin), a *para*-chlorobenzoic acid. It is used for rheumatoid arthritis, gouty arthritis, and osteoarthritis and is a potent prostaglandin inhibitor. It is highly protein bound (90%) and displaces other protein-bound drugs, resulting in potential toxicity. It has a moderate half-life (4.5 hours). Indomethacin is very irritating to the stomach and should be taken with food.

Two other *para*-chlorobenzoic acid derivatives—sulindac (Clinoril) and tolmetin (Tolectin)—produce less severe adverse reactions than indomethacin. Tolmetin is not as highly protein-bound as indomethacin and sulindac, and it has a short half-life. This group of NSAIDs may cause sodium and water retention and increased blood pressure.

Phenylacetic Acid Derivatives

Diclofenac sodium (Voltaren-XR), a phenylacetic acid derivative, has a plasma half-life of 1.2 to 2 hours. Its analgesic and antiinflammatory effects are similar to those of aspirin, but it has minimal to no antipyretic effects. It is indicated for rheumatoid arthritis, osteoarthritis, and ankylosing spondylitis. Diclofenac is available in PO, extended-release, and topical 1% gel preparations. Adverse reactions are similar to those of other NSAIDs.

Ketorolac (Toradol), another phenylacetic acid derivative, is the first injectable NSAID. Like other NSAIDs, it inhibits prostaglandin synthesis, but it has greater analgesic properties than other antiinflammatory agents. Ketorolac is recommended for short-term management of pain. For postsurgical pain, it has shown analgesic efficacy equal or superior to that of opioid analgesics. It is administered intramuscularly in doses of 30 to 60 mg every 6 hours for adults. Ketorolac is also available in PO, IV, and intranasal preparations.

Propionic Acid Derivatives

The propionic acid group is a relatively new group of NSAIDs. These drugs are aspirin-like but have stronger effects and create less GI irritation. Drugs in this group are highly protein-bound, so drug interactions might occur, especially when given with another highly protein-bound drug. Propionic acid derivatives are better tolerated than other NSAIDs. Gastric upset occurs, but it is not as severe as with aspirin and indomethacin. Severe adverse reactions such as blood dyscrasias are not frequently seen. Ibuprofen (Motrin) is the most widely used propionic acid NSAID, and it may be purchased OTC in lower doses (200 mg). Prototype Drug Chart 25-2 details the pharmacologic behavior of ibuprofens. Six other propionic acid agents are fenoprofen calcium (Nalfon), naproxen (Naprosyn), ketoprofen (Orudis), flurbiprofen (Ansaid), and oxaprozin (Daypro).

Pharmacokinetics Ibuprofens are well absorbed from the GI tract. These drugs have a short half-life but are highly protein-bound. If ibuprofen is taken with another highly protein-bound drug, severe side effects may occur. The drug is metabolized in the liver to inactivate metabolites and is excreted as inactive metabolites in the urine.

Pharmacodynamics Ibuprofens inhibit prostaglandin synthesis and are therefore effective in alleviating inflammation and pain. They have a short onset of action, peak concentration time, and duration of action. It may take several days for the antiinflammatory effect to be evident.

There are many drug interactions associated with ibuprofen. It can increase the effects of warfarin (Coumadin), sulfonamides, many of the cephalosporins, and phenytoin. When taken with aspirin, its effect can be decreased. Hypoglycemia may result when ibuprofen is taken with insulin or an oral hypoglycemic drug. There is a high risk of toxicity when ibuprofen is taken concurrently with calcium channel blockers.

Fenamates

The fenamate group includes potent NSAIDs used for acute and chronic arthritic conditions. Like most NSAIDs, gastric irritation is a common side effect of fenamates, and patients with a history of peptic ulcer should avoid taking this group of drugs. Other side effects include edema, dizziness, tinnitus, and pruritus. Two fenamates are meclofenamate sodium monohydrate (Meclomen) and mefenamic acid (Ponstel).

Oxicams

Piroxicam (Feldene), an oxicam, is indicated for long-term arthritic conditions such as rheumatoid arthritis and osteoarthritis. It too can cause gastric problems such as ulceration and epigastric distress, but the incidence is lower than for some other NSAIDs. It is well tolerated, and its major advantage over other NSAIDs is its long half-life, which allows it to be taken only once daily.

Full clinical response to piroxicam may take 1 to 2 weeks. This drug is also highly protein-bound and may interact with

PROTOTYPE DRUG CHART 25-2

Ibuprofen

Drug Class
Nonsteroidal antiinflammatory drug: propionic acid derivative
Trade Names: Motrin, Advil
Pregnancy Category: C (D, third trimester)

Dosage
A: PO: 200-800 mg t.i.d./q.i.d.; *max:* 2400 mg/d

Contraindications
Severe renal or hepatic disease, asthma, peptic ulcer, anticoagulant therapy
Caution: Bleeding disorders, pregnancy, lactation, systemic lupus erythematosus

Drug-Lab-Food Interactions
Drug: Increase bleeding time with oral anticoagulants; increase effects of phenytoin, sulfonamides, warfarin; decrease effect with aspirin; may increase severe side effects of lithium

Pharmacokinetics
Absorption: PO: Well absorbed
Distribution: PB: 90%-99%
Metabolism: t½: 2-4 h
Excretion: In urine, mostly as inactive metabolites; some in bile

Pharmacodynamics
PO: Onset: 1 h
Peak: 2-4 h
Duration: 4-6 h

Therapeutic Effects/Uses
To reduce inflammatory process; to relieve pain; antiinflammatory effect for arthritic conditions; to reduce fever
Mode of Action: Inhibition of prostaglandin synthesis, thus relieving pain and inflammation

Side Effects
Anorexia, nausea, vomiting, diarrhea, edema, rash, purpura, tinnitus, fatigue, dizziness, lightheadedness, anxiety, confusion, fluid retention with edema

Adverse Reactions
GI bleeding
Life-threatening: Blood dyscrasias, cardiac dysrhythmias, nephrotoxicity, anaphylaxis

A, Adult; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t ½,* half-life; *t.i.d.,* three times a day; *y,* year; <, less than; >, greater than.

another highly protein-bound drug if taken together. Piroxicam should not be taken with aspirin or other NSAIDs.

General Side Effects and Adverse Reactions for First-Generation NSAIDs

Most NSAIDs tend to have fewer side effects than aspirin when taken at antiinflammatory doses, but gastric irritation is still a common problem when NSAIDs are taken without food. In addition, sodium and water retention may occur. Alcoholic beverages consumed with NSAIDs may increase gastric irritation and should be avoided.

Nursing Process
Patient-Centered Collaborative Care

Nonsteroidal Antiinflammatory Drug: Ibuprofen

Assessment

- Check patient's history of allergy to NSAIDs such as ibuprofen. If an allergy is present, notify health care provider.
- Obtain a drug and herbal history, and report any possible drug-drug or herb-drug interactions. NSAIDs can increase the effects of phenytoin (Dilantin), sulfonamides, and warfarin. Most NSAIDs are highly protein-bound and can displace other highly protein-bound drugs like warfarin (Coumadin).
- Determine medical history. NSAIDs are contraindicated if patient has severe renal or liver disease, peptic ulcer, or bleeding disorder.
- Assess patient for GI upset and peripheral edema, which are common side effects of NSAIDs.

Nursing Diagnoses

- Risk for injury related to dizziness
- Risk for activity intolerance related to fatigue

Planning

- The patient's inflammatory process will subside in 1 to 3 weeks.

Nursing Interventions

- Observe patient for bleeding gums, petechiae, ecchymoses, or black (tarry) stools. Bleeding time can be prolonged when NSAIDs are taken, especially with a highly protein-bound drug such as warfarin (anticoagulant).
- Report if patient has GI discomfort. Administer NSAIDs at mealtime or with food to prevent GI upset.
- Monitor vital signs and check for peripheral edema, especially in the morning.

- Do not give directions such as "take one blue pill" at a specified time. Instead, provide name and dosage of medication.

Patient Teaching

General

- Inform patient not to take aspirin and acetaminophen with NSAIDs. Taking an NSAID with aspirin could cause GI upset and possible GI bleeding.
- Inform patient to avoid alcohol when taking NSAIDs. GI upset or gastric ulcer may result.
- Alert patient that many herbal products may interact with NSAIDs and could cause bleeding. Doses of NSAIDs and/or herbs may need to be modified to avoid possible bleeding occurrence (Herbal Alert 25-1).
- Direct patient to inform the dentist or surgeon before a procedure when taking ibuprofen or other NSAIDs for a continuous period.
- Warn female patients not to take NSAIDs 1 to 2 days before menstruation to avoid heavy menstrual flow. If discomfort occurs, acetaminophen is usually prescribed.
- Advise pregnant patients to avoid NSAIDs. Congenital abnormalities may occur when NSAIDS are taken during early pregnancy, and excess bleeding might occur during delivery.
- Inform patient that it may take several weeks to experience desired drug effect of some NSAIDs and disease-modifying antirheumatic drugs (DMARDs).

Side Effects

- Educate patient of the common side effects of NSAIDs. Nausea, vomiting, peripheral edema, GI upset, purpura or petechiae, or dizziness might occur. Report occurrences of side effects.

Diet

- Advise patient to take NSAIDs with meals or snacks to reduce GI upset.

Cultural Considerations

- Recognize that patients from various cultural backgrounds respond to pain and inflammation in various ways. In some cultures, the use of drugs to alleviate pain and inflammation is not acceptable. Herbal medicine and acupuncture may be used to alleviate pain.
- Be supportive of patient's methods for pain control. Explain the purpose of medications and their actions and side effects.

Evaluation

- Evaluate the effectiveness of the drug therapy, such as a decrease in pain and in swollen joints and an increase in mobility.

HERBAL ALERT 25-1

NSAIDs

Dong quai, feverfew, garlic, ginger, and ginkgo may cause bleeding when taken with nonsteroidal antiinflammatory drugs (NSAIDs).

Selective COX-2 Inhibitors (Second-Generation NSAIDs)

COX-2 inhibitors became available in the last several years to decrease inflammation and pain. Most NSAIDs are nonselective inhibitors that inhibit COX-1 and COX-2. By inhibiting COX-1, protection of the stomach lining is decreased and clotting time is also decreased, which may benefit the patient with cardiovascular or coronary artery disease (CAD). Selective COX-2 inhibitors are drugs of choice for patients with severe arthritic conditions who need high doses of an antiinflammatory drug, because large doses of NSAIDs may cause peptic ulcer and gastric bleeding.

Currently there is one drug, celecoxib (Celebrex), classified as a COX-2 inhibitor. Nabumetone (Relafen) is a similar drug that can be used; however it is not considered a "true" COX-2 inhibitor. Nabumetone inhibits COX-2 more than COX-1. Celecoxib is described in Prototype Drug Chart 25-3.

SAFETY: Preventing Medication Errors

Do not confuse…

- **Celebrex** (COX-2 inhibitor) with **Celexa** (selective serotonin reuptake inhibitor for depression) or **Cerebyx** (hydantoin anticonvulsant).

Use of NSAIDs in Older Adults

Older adults frequently use NSAIDs to treat pain associated with inflammation caused by osteoarthritis, rheumatoid arthritis, and neuromuscular-skeletal disorders. As older adults age, the number of drugs taken daily increases; therefore drug interactions are more common, especially when numerous drugs are taken with NSAIDs. With the use of NSAIDs, GI distress (including ulceration) is four times more common in older adults; hospitalization is often necessary.

The introduction of COX-2 inhibitors (second-generation NSAIDs) has decreased the incidence of GI problems associated with NSAID use; however, edema is likely to occur. Renal function should be evaluated, and older adults should increase their fluid intake for adequate hydration. To decrease possible complications, the NSAID dose should be lowered.

CORTICOSTEROIDS

Corticosteroids such as prednisone, prednisolone, and dexamethasone are frequently used as antiinflammatory agents. This group of drugs controls inflammation by suppressing or preventing many of the components of the inflammatory process at the injured site. Corticosteroids have been widely prescribed for arthritic conditions, and although they are not the drug of choice for arthritis because of their numerous side effects, they are frequently used to control arthritic flareups.

PROTOTYPE DRUG CHART 25-3

Celecoxib

Drug Class

Nonsteroidal antiinflammatory: COX-2 inhibitor
Trade Name: Celebrex
Pregnancy Category: C (first and second trimester), D (third trimester)

Dosage

Arthritis:
A: PO: 100 mg b.i.d. or 200 mg daily
Dysmenorrhea:
A: PO: 400 mg first dose, follow with 200 mg same day if needed, and then 200 mg b.i.d. PRN

Contraindications

Hypersensitivity, advanced renal disease, severe hepatic failure, anemia, concurrent use of diuretics and ACE inhibitors
Caution: Renal or hepatic dysfunction, hypertension, fluid retention, heart failure, infection, history of GI bleeding or ulceration, concurrent anticoagulant therapy, steroids, or alcohol use

Drug-Lab-Food Interactions

Drug: Decrease effect of ACE inhibitors, increased INR and GI bleeding with warfarin, may increase toxicity with lithium, fluconazole increases celecoxib levels.

Pharmacokinetics

Absorption: Well-absorbed in GI tract
Distribution: PB: 97%
Metabolism: t½: 11.2 h
Excretion: Primarily in feces

Pharmacodynamics

PO: Onset: UK
Peak: 3 h
Duration: UK

Therapeutic Effects/Uses

To treat osteoarthritis and rheumatoid arthritis, to relieve dysmenorrhea
Mode of Action: Inhibits COX-2 (which normally promotes prostaglandin synthesis and inflammatory response) but does not inhibit COX-1

Side Effects

Headache, dizziness, sinusitis, nausea, flatulence, diarrhea, rash

Adverse Reactions

Peripheral edema

A, Adult; *ACE,* angiotensin-converting enzyme; *b.i.d.,* twice a day; *COX,* cyclooxygenase; *GI,* gastrointestinal; *h,* hour; *INR,* international normalized ratio; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *t ½,* half-life; *UK,* unknown.

The half-life of a corticosteroid is long (greater than 24 hours), and it is administered once a day in a large prescribed dose. When discontinuing steroid therapy, the dosage should be tapered over a period of 5 to 10 days. Steroids are discussed in more detail in Chapter 51.

DISEASE-MODIFYING ANTIRHEUMATIC DRUGS

When NSAIDs do not control immune-mediated arthritic disease sufficiently, other drugs, although more toxic, can be prescribed to alter the disease process. The **disease-modifying antirheumatic drugs (DMARDs)** include immunosuppressive agents, immunomodulators, and antimalarials. DMARDs help alleviate the symptoms of rheumatoid arthritis for the 2 million persons in the United States affected by the disorder. DMARDs are described in Table 25-3.

Immunosuppressive Agents

Immunosuppressives are used to treat refractory rheumatoid arthritis (arthritis that does not respond to antiinflammatory drugs). In low doses, selected immunosuppressive agents have been effective in the treatment of rheumatoid arthritis. Drugs such as azathioprine (Imuran), cyclophosphamide (Cytoxan), and methotrexate (Mexate), primarily used to suppress cancer growth and proliferation, might be used to suppress the inflammatory process of rheumatoid arthritis when other treatments fail. In one study of patients receiving cyclophosphamide, few new erosions of joint cartilage were present, suggesting that the disease process was not active.

Immunomodulators

Immunomodulators treat moderate to severe rheumatoid arthritis by disrupting the inflammatory process and delaying disease progression. Interleukin (IL-1) receptor antagonists and tumor necrosis factor (TNF) blockers are two groups of drugs classified as immunomodulators.

Anakinra (Kineret), an IL-1 receptor antagonist, blocks activity of IL-1 by inhibiting it from binding to interleukin receptors located in cartilage and bone. IL-1 is a proinflammatory cytokine that contributes to synovial inflammation and joint destruction. Anakinra is administered subcutaneously. The peak is 3 to 7 hours, and the half-life is 6 hours.

TNF blockers bind to TNF and block it from attaching to TNF receptors on synovial cell surfaces. By neutralizing TNF, a contributor to synovitis, inflammatory disease process is delayed. Etanercept (Enbrel) was the first TNF blocker developed and is administered subcutaneously. The peak half-life is 115 hours. Signs and symptoms of rheumatoid arthritis are suppressed rapidly with etanercept therapy but reappear if the drug is discontinued. Other TNF blockers include infliximab (Remicade), adalimumab (Humira), and leflunomide (Arava). Infliximab is administered intravenously (IV) over at least 2 hours, adalimumab is administered subcutaneously,

TABLE 25-3 ANTIINFLAMMATORY DRUGS: DMARDs

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
golimumab (Simponi)	A: subQ: 50 mg every month	For treatment of rheumatoid arthritis. Adverse effects include blood dyscrasias. Pregnancy category: B; PB: UK; t½: 2 weeks
anakinra (Kineret)	A: subQ: 100 mg daily	For treatment of rheumatoid arthritis unresponsive to other DMARDs. Pregnancy category: B; PB: UK; t½: 4 to 6 h
etanercept (Enbrel)	A: subQ: 25 mg 2 times/wk or 50 mg/wk; *max:* 100 mg/wk C >4 y: subQ: 0.4 mg/kg 2 times/wk; *max:* 50 mg/wk	For treatment of rheumatoid arthritis unresponsive to other DMARDs. Pregnancy category: B; PB: UK; t½: 102 h
infliximab (Remicade)	See Prototype Drug Chart 25-4.	
rituximab (Rituxan)	A: IV: 1000 mg on day 1 and day 15 with methotrexate, then q16-24wks	For treatment of moderate to severe rheumatoid arthritis. Give methylpresnisolone 100 mg prior to each dose to decrease infusion reactions. Pregnancy category: C; PB: UK; t½: 60 to 174 h
adalimumab (Humira)	A: subQ: 40 mg every 2 wk	For treatment of rheumatoid arthritis unresponsive to other DMARDs. Pregnancy category: B; PB: UK; t½: 10 to 20 d
tocilizumab (Actemra)	A: IV: 4 mg/kg over 1 hour every 4 weeks; *max:* 800 mg/dose	For treatment of moderate to severe rheumatoid arthritis. Approved in 2010. Adverse effects include infection, GI perforation, hypertension. Pregnancy category: C; PB: UK; t½: 11 to 13 d
leflunomide (Arava)	A: PO: 100 mg/d for 3 d initially, then 20 mg/d	For treatment of rheumatoid arthritis unresponsive to other DMARDs. Pregnancy category: X; PB: 99%; t½: 19 d
abatacept (Orencia)	A: IV: 500 mg for <60 kg; 750 mg for 60 to 100 kg; 1 gram for >100 kg q2wk; initial dose followed by additional doses at 2- and 4-week intervals, then q4wk	For moderate to severe rheumatoid arthritis. Pregnancy category: C; PB: UK; t½: 13 d
tofacitinib (Xeljanz)	A: PO: 5 mg b.i.d.	For treatment of moderate to severe rheumatoid arthritis. Adverse effects include infection, headache, and hypertension. Pregnancy category: C; PB: 40%; t½: 3 h
tocilizumab (Actemra)	A: IV: 4 mg/kg q4wk initially; may increase to 8 mg/kg q4wk; *max:* 800 mg/dose q4wk	For treatment of moderate to severe rheumatoid arthritis unresponsive to other DMARDs. Adverse effects include gastritis, mouth ulcerations, upper abdominal pain, and hypertension. Pregnancy category: C; PB: UK; t½: up to 3 days

A, Adult; *C,* child; *d,* day; *DMARD,* disease-modifying antirheumatic drug;*GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *maint,* maintenance; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *t½,* half-life; *TD,* transdermal; *UK,* unknown; *wk,* week; *y,* year; *>,* greater than; *<,* less than.

and leflunomide is administered orally. Infliximab is described in Prototype Drug Chart 25-4.

Both IL-1 receptor antagonists and TNF blockers predispose the patient to severe infections; they are contraindicated in active infection and should be discontinued when an infection occurs. Immunomodulators are usually very expensive.

Nursing Process
Patient-Centered Collaborative Care

Infliximab (Remicade)

Assessment
- Determine a medical history. Ask patient if there is any history of seizures, diabetes mellitus, multiple sclerosis, or kidney or liver disease. Aspirin can cause gastric irritation. It prolongs bleeding time by inhibiting platelet aggregation.
- Obtain baseline renal and liver function tests.

Nursing Diagnoses
- Impaired physical mobility related to severe pain
- Chronic pain related to tissue swelling from rheumatoid arthritis

Planning
- The patient's pain will be reduced within 12 to 24 hours.
- The patient's inflammation will be reduced within 1 week.

Nursing Interventions
- Obtain negative tuberculosis skin test prior to initiating infliximab therapy.
- Monitor patient for signs and symptoms of infection. If a serious infection occurs while receiving infliximab therapy, antibiotic therapy should be initiated and infliximab discontinued.
- Monitor laboratory tests for blood dyscrasias (CBC), and renal and liver function (BUN, serum creatinine, ALP, AST, ALT).

PROTOTYPE DRUG CHART 25-4

Infliximab

Drug Class
Immunomodulator: tumor necrosis factor blocker
Trade Name: Remicade
Pregnancy Category: B

Dosage
Rheumatoid arthritis:
A: IV: 3 mg/kg over 2 h; then 3 mg/kg on wk 2 and 6; and then q8wk
Crohn's disease:
A: IV: 5 mg/kg over 2 h initially and on wk 2 and 6, and then q8wk

Contraindications
Hypersensitivity, heart failure
Caution: Renal or hepatic dysfunction, bone marrow suppression, diabetes mellitus, immunosuppression, multiple sclerosis, seizures, older adults

Drug-Lab-Food Interactions
Drug: May decrease effectiveness of vaccines; concurrent immunosuppressives may increase risk for infection or adverse effects

Pharmacokinetics
Absorption: UK
Distribution: UK
Metabolism: t½: 8-9.5 d
Excretion: UK

Pharmacodynamics
IV: Onset: UK
Peak: UK
Duration: UK

Therapeutic Effects/Uses
To treat moderate to severe rheumatoid arthritis and Crohn's disease
Mode of Action: Binds to TNF and blocks it from attaching to TNF receptors on synovial cell surfaces. Reduces infiltration of inflammatory cells, and delays inflammatory process.

Side Effects
Headache, dizziness, coughing, fatigue, chills, hot flashes, anxiety, insomnia, depression, nausea, vomiting, diarrhea, constipation, flatulence, weight loss, rash, alopecia, dry skin, urinary frequency

Adverse Reactions
Severe infections, chest pain, hypotension, hypertension, bradycardia, seizures, increased hepatic enzymes, neutropenia, pancytopenia, Stevens-Johnson syndrome

A, Adult; *d*, day; *IV*, intravenous; *t ½*, half-life; *UK*, unknown; *wk*, week.

- Flush IV tubing with normal saline before and after administration. Deliver IV medication through a 1.2 micron or less filter.
- Administer each dose over a minimum of 2 hours.
- Discontinue IV dose of infliximab if the patient develops acute infusion reaction (e.g., chest pain, fever, chills, dyspnea, pruritus, urticaria, hypotension or hypertension).
- Monitor patient up to 2 hours post-infusion for acute infusion reaction.

Patient Teaching

General

- Encourage patient to keep medical appointments and have regular scheduled laboratory tests for renal, liver, and complete blood count functions for early detection of blood dyscrasias and renal and liver damage.
- Advise patient to avoid live vaccine while taking infliximab.

Side Effects

- Teach patient to report dizziness, chills, depression, dyspnea, severe infections, seizures, fatigue, or rash immediately.
- Teach patient to report severe infections immediately.

Cultural Considerations

- Provide additional explanation as needed related to the disease process and the purpose of the drug and its side effects.
- Identify conflicts in values and beliefs.
- Suggest follow-up by a community health nurse to determine patient's compliance to the drug regimen and the effectiveness of the prescribed drug therapy.

Evaluation

- Evaluate patient's response to the DMARD. If pain persists, drug regimen may need modification.
- Determine the presence of adverse reactions. Drug therapy for pain may need to be changed.

Antimalarials

Antimalarial drugs may be used to treat rheumatoid arthritis when other methods of treatment fail. The mechanism of action of antimalarials in suppressing rheumatoid arthritis is unclear. The effect may take 4 to 12 weeks to become apparent, and antimalarials are usually used in combination with NSAIDs in patients whose arthritis is not under control.

ANTIGOUT DRUGS

Gout is an inflammatory condition that attacks joints, tendons, and other tissues. It may be called *gouty arthritis.* The most common site of acute gouty inflammation is at the joint of the big toe. Gout is characterized by a uric acid metabolism disorder and a defect in purine (products of certain proteins) metabolism, which results in an increase in urates (uric acid salts) and an accumulation of uric acid (hyperuricemia) or an ineffective clearance of uric acid by the kidneys. Uric acid solubility is poor in acid urine, and urate crystals may form, causing urate calculi. Gout may appear as bumps, or *tophi,* in the subcutaneous tissue of earlobes, elbows, hands, and the base of the large toe. In addition to tophi, the complications of untreated or prolonged periods of gout include gouty arthritis, urinary calculi, and gouty nephropathy.

Fluid intake should be increased while taking antigout drugs to promote uric acid excretion and prevent renal calculi. Foods high in purine (e.g., organ meats, sardines, salmon, gravy, herring, liver, meat soups) and alcohol (especially beer) should be avoided. Alcohol causes both an overproduction and underexcretion of uric acid. Acetaminophen should be taken for discomfort instead of aspirin (salicylic acid) to reduce acidity.

Antiinflammatory Gout Drug: Colchicine

The first drug used to treat gout was colchicine, introduced in 1936. This antiinflammatory gout drug inhibits the migration of leukocytes to the inflamed site. It is effective in alleviating acute symptoms of gout, but it is not effective in decreasing inflammation occurring in other inflammatory disorders. Colchicine does not inhibit uric acid synthesis and does not promote uric acid excretion. It should not be used if the patient has a severe renal, cardiac, or GI problem. Gastric irritation is a common problem, so colchicine should be taken with food. With high doses, nausea, vomiting, diarrhea, or abdominal pain occurs in approximately 75% of patients taking the drug.

Colchicine is well absorbed in the GI tract, and its peak concentration time is within 2 hours. Most of the drug is excreted in the feces, but 10% to 20% is excreted in the urine.

Uric Acid Inhibitor

Allopurinol (Zyloprim), first marketed in 1963, is not an antiinflammatory drug; instead, it inhibits the final steps of uric acid biosynthesis and therefore lowers serum uric acid levels, preventing the precipitation of an attack. This drug is frequently used as a prophylactic to prevent gout. It is a drug of choice for patients with chronic tophaceous gout. Allopurinol is also indicated for gout patients with renal impairment. It is useful for patients who have renal obstructions caused by uric acid stones and for patients with blood disorders such as leukemia and polycythemia vera. It is also given to patients who do not respond well to uricosuric drugs such as probenecid. Increased fluid intake is recommended to promote diuresis and alkalinization of the urine. Prototype Drug Chart 25-5 presents the pharmacologic behavior of allopurinol.

Pharmacokinetics Eighty percent of allopurinol is absorbed from the GI tract. Biosynthesis of uric acid occurs in the liver in pure form and active metabolites. The half-life of the drug itself is 2 to 3 hours and 20 to 24 hours for its active metabolites. The protein-binding percentage is unknown. Approximately 80% to 100% of allopurinol and its metabolites are excreted in urine.

Pharmacodynamics Allopurinol inhibits the production of uric acid by inhibiting the enzyme xanthine oxidase, which is needed in the synthesis of uric acid. Allopurinol also improves the solubility of uric acid. Its onset of action occurs within 30 to 60 minutes; its peak time averages 2 to 4 hours. Allopurinol has a long duration of action.

Alcohol, caffeine, and thiazide diuretics increase the uric acid level. Use of ampicillin or amoxicillin with allopurinol increases the risk of rash formation. Allopurinol can increase the effect of warfarin (Coumadin) and oral hypoglycemic drugs.

Uricosurics

Uricosurics increase the rate of uric acid excretion by inhibiting its reabsorption. These drugs are effective in alleviating chronic gout, but they should not be used during acute attacks. Probenecid (Benemid) is a uricosuric that has been available since 1945. It blocks the reabsorption of uric acid and promotes its excretion. Probenecid can be taken with colchicine. To begin initial therapy for relieving symptoms of gout and inhibiting uric acid reabsorption, small doses of colchicine should be given before adding probenecid. If gastric irritation occurs, probenecid should be taken with meals. It has an average half-life of 8 to 10 hours and is 85% to 95% protein-bound. Use caution when administering this drug with other highly protein-bound drugs.

Another uricosuric is sulfinpyrazone (Anturane). This drug is a metabolite of phenylbutazone and is more potent than probenecid. Sulfinpyrazone should be taken with meals or with antacids to prevent gastric irritation. Severe blood dyscrasias might occur, especially in patients with a history of blood dyscrasia. Table 25-4 gives dosages and considerations for the commonly used antigout drugs.

Side Effects and Adverse Reactions

Side effects may include flushed skin, sore gums, and headache. Kidney stones resulting from the uric acid could be prevented by increasing water intake and maintaining a urine pH above 6. Blood dyscrasias occur rarely. Aspirin use should be avoided, because it causes uric acid retention.

Nursing Process

Patient-Centered Collaborative Care

Antigout: Allopurinol

Assessment

- Obtain medical history from patient of any gastric, renal, cardiac, or liver disorders. Antigout drugs are excreted via kidneys, so sufficient renal function is needed. Drug dosage and drug selection might need to be changed.

PROTOTYPE DRUG CHART 25-5

Allopurinol

Drug Class
Antigout: uric acid biosynthesis inhibitor
Trade Names: Zyloprim, Aloprim, 🍁 Apo-Allopurinol
Pregnancy Category: C

Dosage
A: PO: Initially: 100 mg/d, may increase; 200-300 mg/d (for mild gout); 400-600 mg/d (for severe gout); *max:* 800 mg/d
C ≤10 y: PO: 10 mg/kg/d in 2-3 divided doses; *max:* 300 mg/dose

Contraindications
Hypersensitivity, severe renal disease
Caution: Hepatic disorder

Drug-Lab-Food Interactions
Drug: Increase effect of warfarin, phenytoin, theophylline, anticancer drugs, ACE inhibitors; increase rash with ampicillin, amoxicillin; increase toxicity with thiazide diuretics; decrease allopurinol effect with antacids
Lab: Increase AST, ALT, BUN

Pharmacokinetics
Absorption: PO: 80% absorbed
Distribution: PB: UK
Metabolism: t½: 1-2 h
Excretion: 80%-100% in urine

Pharmacodynamics
PO: Onset: 0.5-1 h
Peak: 2-4 h
Duration: 18-30 h

Therapeutic Effects/Uses
To treat gout and hyperuricemia; prevent urate calculi
Mode of Action: Reduction of uric acid synthesis

Side Effects
Anorexia, nausea, vomiting, diarrhea, stomatitis, dizziness, headache, rash, pruritus, malaise, metallic taste, diaphoresis, edema, erectile dysfunction, peripheral neuropathy

Adverse Reactions
Cataracts, retinopathy, bradycardia, depression
Life-threatening: Bone marrow depression, aplastic anemia, thrombocytopenia, neutropenia, agranulocytosis, leukopenia

A, Adult; *ACE,* angiotensin-converting enzyme; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *BUN,* blood urea nitrogen; *C,* child; *d,* day; *h,* hour; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *t ½,* half-life; *UK,* unknown; *y,* year; ≤, less than or equal to; 🍁, Canadian drug name.

TABLE 25-4 ANTIGOUT DRUGS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Antiinflammatory Gout Drugs		
colchicine (Colcrys)	Acute gout attack: A: PO: Initially: 0.6-1.2 mg; 0.6 mg in 1 h; *max:* 2.4 mg/d Prophylaxis: A: PO: 0.6 mg q.d./b.i.d.; *max:* 1.2 mg/d	For acute gout and prophylaxis of recurrent gouty arthritis. Not for patients with renal or gastric disorders. Take with food. Pregnancy category: C; PB: 34%-44%; t½: 26.6-31.2 h
Uric Acid Biosynthesis Inhibitors		
allopurinol (Zyloprim)	See Prototype Drug Chart 25-5.	
febuxostat (Uloric)	A: PO: 40-80 mg/d; *max:* 120 mg/d	For hyperuricemia in gout. Blocks metabolism of xanthines to uric acid. Is more selective for xanthine oxidase than allopurinol. Side effects include GI distress and dysrhythmias. Pregnancy category: C; PB: 99.2%; t½: 5-8 h
Uricosurics		
probenecid	A: PO: First week: 250 mg b.i.d.; *maint:* 500 mg b.i.d.; *max:* 2 g/d C <50 kg: PO: 25-40 mg/kg/d in 4 divided doses	For hyperuricemia; promotes urinary excretion of uric acid. For gout and gouty arthritis. Alkaline urine helps prevent renal stones. Increase fluid intake. Pregnancy category: B; PB: 75%-95%; t½: 3-12 h
sulfinpyrazone (Anturane)	A: PO: Week 1: 100-200 mg b.i.d.; *maint:* 200-400 mg b.i.d.; may reduce to 200 mg/d; *max:* 800 mg/d	Management of hyperuricemia; decreases gouty attacks. May cause GI distress. Take with food. Pregnancy category: C; PB: 98%-99%; t½: 4 h

A, Adult; *b.i.d.,* twice a day; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *t ½,* half-life; <, less than.

- Obtain drug history. Report possible drug-drug interactions (see Prototype Drug Chart 25-2).
- Assess serum uric acid value for future comparison.
- Record urine output. Use initial urine output for future comparison.
- Check laboratory tests (e.g., blood urea nitrogen [BUN], serum creatinine, alkaline phosphatase [ALP], aspartate aminotransferase [AST], alanine aminotransferase [ALT], lactate dehydrogenase [LDH]), and compare with future laboratory test results.

Nursing Diagnoses

- Impaired tissue integrity related to inflammation of great toe
- Acute pain related to tissue swelling

Planning

- Patient's pain from gout will be absent or controlled without side effects.

Nursing Interventions

- Report GI symptoms, gastric pain, nausea, vomiting, or diarrhea when taking antigout drugs. Take these drugs with food to alleviate gastric distress.
- Record patient's urine output. Because the drugs and uric acid are excreted through the urine, kidney stones might occur, so both water intake and urine output should be increased.
- Monitor laboratory tests for renal and liver function (BUN, serum creatinine, ALP, AST, ALT).

Patient Teaching

General

- Encourage patient to keep medical appointments and have regular scheduled laboratory tests for renal, liver, and complete blood count functions. Some antigout drugs may cause blood dyscrasias; blood tests should be monitored.
- Instruct patient to increase fluid intake; it will increase drug and uric acid excretion.

Side Effects

- Inform patient to report to health care provider side effects of antigout drugs: anorexia, nausea, vomiting, diarrhea, stomatitis, dizziness, rash, pruritus, and metallic taste.
- Advise patient to have a yearly eye examination because visual changes can result from prolonged use of allopurinol.

Diet

- Warn patient to avoid alcohol and caffeine because they can increase uric acid levels.
- Suggest to patient not to take large doses of vitamin C while taking allopurinol; kidney stones may occur.
- Tell patient not to ingest foods high in purine content (e.g., organ meats, salmon, sardines, gravy, legumes). Purine foods increase uric acid levels.
- Direct patient to report any gastric distress. Encourage patient to take antigout drugs with food or at mealtime.

Cultural Considerations

- Provide additional explanation as needed related to the disease process and the purpose of the drug and its side effects.
- Identify conflicts in values and beliefs.
- Suggest follow-up by a community health nurse to determine patient's compliance to the drug regimen and the effectiveness of the prescribed drug therapy.

Evaluation

- Evaluate patient's response to the antigout drug. If pain persists, drug regimen may need modification.
- Determine the presence of adverse reactions. Drug therapy for gout pain may need to be changed.

CRITICAL THINKING CASE STUDY

PQ, a 72-year-old woman, had taken 650 mg of aspirin four times a day for 8 months to alleviate her chronic symptoms of pain and inflammation associated with arthritis. Four weeks ago, a peptic ulcer developed.

1. Explain the process in which PQ could have a peptic ulcer. How could this have been prevented?
2. Compare the similarities and differences in the side effects of salicylates with those of acetic acid agents, propionic acid agents, COX-2 inhibitors, and phenylacetic acid.
3. What patient teaching points should PQ receive before and during the time she takes aspirin?
4. How would COX-2 inhibitors prevent the development of a peptic ulcer?
5. Would DMARDs be more helpful in alleviating PQ's symptoms? Explain your answer.
6. Compare the differences in the various types of DMARDs.

NCLEX STUDY QUESTIONS

1. A patient is taking ibuprofen. The nurse understands that COX-1 and COX-2 inhibitors are different in that ibuprofen is more likely than celecoxib to cause which adverse effect?
   - a. Fever
   - b. Constipation
   - c. Peptic ulcer disease
   - d. Metallic taste when eating
2. When teaching a patient who is receiving allopurinol, what should the nurse encourage the patient to do?
   - a. Eat more meat.
   - b. Increase vitamin C intake.
   - c. Have annual eye examinations.
   - d. Take medication 2 hours before meals.
3. A patient is admitted to the hospital with an acute gout attack. The nurse expects that which medication will be ordered to treat acute gout?
   - a. colchicine
   - b. allopurinol
   - c. probenecid
   - d. sulfinpyrazone
4. A patient is taking aspirin for arthritis. Which adverse reaction should the nurse teach the patient to report to the health care provider?
   - a. Tinnitus
   - b. Seizures
   - c. Sinusitis
   - d. Palpitations
5. The nurse is teaching a patient about taking aspirin. Which are important points for the nurse to include? (Select all that apply.)
   - a. Advise the patient to avoid alcohol while taking aspirin.
   - b. Instruct the patient to take aspirin before meals on an empty stomach.
   - c. Instruct the patient to inform the dentist of the aspirin dosage before having dental work.
   - d. Instruct the patient to inform the surgeon of the aspirin dosage before having surgery.
   - e. Suggest that aspirin may be given to children for flu symptoms.
6. A patient is taking infliximab (Remicade) and asks the nurse what side effects/adverse reactions to expect from this drug. The nurse lists which side effects? (Select all that apply.)
   - a. Fatigue
   - b. Headache
   - c. Chest pain
   - d. Renal damage
   - e. Severe infections

Answers: 1, c; 2, c; 3, a; 4, a; 5, a, c, d; 6, a, b, c, e.

OBJECTIVES

- Differentiate between acute and chronic pain.
- Compare indications for nonopioid and opioid analgesics.
- Describe the serum therapeutic ranges of acetaminophen and aspirin.
- Contrast the side effects of aspirin and opioids.
- Explain the methadone treatment program.
- Discuss nursing interventions and patient teaching related to nonopioid and opioid analgesics.
- Apply the nursing process to the patient with patient-controlled analgesia.

Pain is an unpleasant sensory and emotional experience related to tissue injury. Due to the subjective nature of pain, the nurse must be knowledgeable and skillful in the assessment and measurement of pain to achieve optimal pain management.

Pain management is regarded as such a significant component of nursing care that pain has become known as the "fifth vital sign." The Joint Commission (TJC) has incorporated the assessment, documentation, and management of pain into its 2003 standards, which reflects the importance of this vital sign. The nurse's role is to assess the patient's pain level, alleviate the patient's pain through nonpharmacologic and pharmacologic treatments, thoroughly document the patient's response to treatment, and teach patients and their significant others to manage pain control themselves when appropriate.

An individual's **pain threshold** reflects the level of stimulus needed to create a painful sensation. Individual genetic makeup contributes to the variations in pain threshold from person to person. The mu (μ) opioid receptor gene controls the number of μ receptors present. When an individual has a large amount of μ receptors, the pain threshold is high and pain sensitivity is reduced.

The amount of pain a person can endure without having it interfere with normal functioning is called **pain tolerance.** This psychological aspect of pain varies greatly in individuals, because it is very subjective. Pain tolerance is influenced by factors such as age, gender, culture, ethnicity, previous experience, anxiety level, and specific circumstances.

Analgesics, both nonopioid and opioid, are prescribed for the relief of pain. The choice of analgesic depends upon the severity of the pain. Mild to moderate pain is frequently relieved with the use of nonopioid (also known as nonnarcotic) analgesics. Moderate to severe pain usually requires an opioid (also known as narcotic) analgesic.

Drugs used for pain relief are presented in this chapter. Many of the same nonopioid analgesics that are taken for pain, such as the **nonsteroidal antiinflammatory drugs (NSAIDs)**, are also taken for antiinflammatory purposes. This application for these drugs is covered in Chapter 25.

The most common classification of pain is by duration. Acute pain can be mild, moderate, or severe and is usually associated with a specific tissue injury. The onset of acute pain is usually sudden and of short duration. Chronic pain usually has a vague origin and onset with a prolonged duration.

Pain may also be classified by its origin. **Nociceptors** (sensory pain receptors) are activated by noxious stimuli (mechanical, thermal, and chemical) in peripheral tissues. When tissue damage occurs, injured cells release chemical mediators that affect the exposed nerve endings of the nociceptors. Pain that originates from tissue injury is nociceptor pain, which includes somatic (structural tissues: bones, muscles) and visceral (organ) pain. **Neuropathic pain** is an unusual sensory disturbance often involving neural supersensitivity. This pain is due to injury or disease of the peripheral or central nervous system (CNS). The patient with neuropathic pain usually complains of burning, tingling, or electrical shocks in the affected area, often triggered by light touch. Diabetic neuropathy associated with diabetes mellitus is an example of peripheral neuropathic pain. Severe, intractable pain from a herniated disk or spinal cord injury is evidence of neuropathic pain in the CNS.

PATHOPHYSIOLOGY

The most common pain theory is called the gate theory, proposed by Melzack and Wall in 1965. According to this theory, tissue injury activates nociceptors and causes the release of chemical mediators such as substance P, prostaglandins, bradykinin, histamine, serotonin, acetylcholine, glutamate, adenosine triphosphate, leukotrienes, and potassium. These substances initiate an action potential along a sensory nerve fiber and sensitize pain receptors. Nociceptive action potentials are transmitted via afferent nerve fibers. One type of pain fiber that primarily transmits impulses from the periphery is the A delta (δ) fiber. Because A δ pain fibers are wrapped in a myelin sheath, they transmit impulses rapidly in acute pain. The C fiber is a type of pain fiber that is small and unmyelinated, and because C fibers are unmyelinated, they transmit impulses slowly. C fibers are more often associated with chronic, dull pain.

A pain signal begins at the nociceptors in the periphery and proceeds throughout the CNS. Knowing how and where pharmacologic agents work is essential to controlling pain. The body produces neurohormones called **endorphins** (peptides) that naturally suppress pain conduction, although the method is not completely understood. Opioids such as morphine activate the same receptors as endorphins to reduce pain. NSAIDs control pain at the peripheral level by blocking the action of cyclooxygenase (pain-sensitizing chemical) and interfering with the production of prostaglandins. Cortisone decreases pain by blocking the action of phospholipase, reducing the production of both prostaglandins and leukotrienes. In neuropathic pain, anticonvulsant drugs prevent the production of nerve impulses by stabilizing the neuronal membrane and inactivating peripheral sodium channels.

To ascertain severity of pain, the health care provider should ask the patient to rate the degree of pain on a scale of 1 to 10, with 10 being the worst or most severe pain. The patient's comfort level should also be determined. A patient who indicates a pain level of 9 may verbalize a decrease in pain to a level of 3 within 30 to 45 minutes after receiving pain medication. Table 26-1 lists the types of pain and the drug groups that may be effective in relieving each type of pain.

Undertreatment of Pain

Undertreatment of pain is a major issue in health care today. The National Pharmaceutical Council and TJC state that up to 75% of patients have unrelieved pain. Some reasons for undertreatment are sociocultural variables that mediate a patient's willingness to acknowledge being in pain, the patient's inability to describe pain, the nurse's inability to

TABLE 26-1 TYPES OF PAIN

TYPE OF PAIN	DEFINITION	DRUG TREATMENT
Acute	Pain occurs suddenly and responds to treatment; can result from trauma, tissue injury, inflammation, or surgery	Mild pain: Scheduled nonopioid (acetaminophen, NSAIDs q6h) Moderate pain: Scheduled combination of nonopioid and opioid (oxycodone 5 mg and acetaminophen 325 mg q4h) Severe pain: Scheduled potent opioid (morphine 15 mg q4h)
Chronic	Pain persists for greater than 6 months and is difficult to treat or control	Nonopioid drugs are suggested. Opioids, if used, should meet these criteria: • Oral or transdermal • Long duration of action • Include adjunct therapy • Cause minimal respiratory depression
Cancer	Pain from pressure on nerves and organs, blockage to blood supply, or metastasis to bone	NSAIDs and opioid drugs administered PO, transdermal, IM, IV, or PCA
Somatic	Pain of skeletal muscle, ligaments, and joints	Nonopioids: NSAIDs; also act as antiinflammatories and muscle relaxants
Superficial	Pain from surface areas such as skin and mucous membranes	Mild pain: Nonopioid Moderate pain: Combination of opioid and nonopioid analgesic drug
Vascular	Pain from vascular or perivascular tissues contributing to headaches or migraines	Nonopioid drugs
Visceral	Pain from smooth muscle and organs	Opioid drugs

IM, Intramuscular; *IV,* intravenous; *NSAIDs*, nonsteroidal antiinflammatory drugs; *PCA,* patient-controlled analgesia; *PO,* by mouth.

measure pain, lack of regular pain assessment rounds, attitudes of the health care team, an unwillingness to believe the patient's report of pain, inaccurate knowledge of the health care provider concerning addiction and tolerance, and prescription of an inadequate analgesic dose. Many scales and instruments are available to the nurse for assessment and measurement of the patient's pain level.

Unrelieved pain leads to a multitude of harmful effects involving almost all organs of the body. As a result of unrelieved pain, the patient may develop increased respiratory rate and heart rate, hypertension, increased stress response, urinary retention, fluid overload, electrolyte imbalance, glucose intolerance, hyperglycemia, pneumonia, atelectasis, anorexia, paralytic ileus, constipation, weakness, confusion, and infection.

In addition to psychological and physical suffering, inadequate pain management leads to high health care costs. It is estimated the cost of extended hospital stays, readmissions to the hospital, and outpatient visits due to inadequate pain management exceeds $100 billion per year.

NONOPIOID ANALGESICS

Nonopioid analgesics (aspirin, acetaminophen, ibuprofen, naproxen) are less potent than opioid analgesics. They are used to treat mild to moderate pain. Nonopioids are usually purchased over-the-counter (OTC), but COX-2 inhibitors require a prescription. Nonopioids are effective for the dull, throbbing pain of headaches, dysmenorrhea (menstrual pain), inflammation, minor abrasions, muscular aches and pain, and mild to moderate arthritis. Most analgesics also have an antipyretic effect and will lower an elevated body temperature. Some, such as aspirin, have antiinflammatory and antiplatelet effects as well.

Nonsteroidal Antiinflammatory Drugs

All NSAIDs have an analgesic effect as well as an antipyretic and antiinflammatory action. NSAIDs such as aspirin (ASA), ibuprofen (Motrin, Advil), and naproxen (Aleve) can be purchased as OTC drugs. Aspirin, a salicylate NSAID, is the oldest nonopioid analgesic drug still in use. Adolf Bayer marketed the original formulation in 1899, and currently aspirin can be purchased under many names and with added ingredients. Examples are Bufferin, Ecotrin (enteric-coated tablet), Anacin (containing caffeine), and Alka-Seltzer.

Aspirin should not be used in children younger than 12 years of age, and it is contraindicated for any elevated temperature, regardless of the cause, because of the danger of Reye's syndrome (neurologic problems associated with viral infection treated with salicylates). In these circumstances, acetaminophen (Tylenol) is recommended instead of aspirin.

In addition to its analgesic, antipyretic, and antiinflammatory properties, aspirin decreases platelet aggregation (clotting). Some health care providers may therefore prescribe one 81-mg, 162-mg, or 325-mg aspirin tablet every day or one 325-mg tablet every other day as a preventive measure against transient ischemic attacks (TIAs, or "small strokes"), heart attacks, or any thromboembolic episode. Aspirin is discussed in depth in Chapter 25 along with other NSAIDs.

Aspirin and other NSAIDs relieve pain by inhibiting biosynthesis of prostaglandin by different forms of the enzyme cyclooxygenase (COX). Inhibition of COX-2 decreases inflammation and pain, but inhibition of COX-1 decreases protection of the stomach lining. As a result of an NSAID's inhibition of COX-1, stomach ulcers and bleeding may occur. Aspirin is the drug of choice for alleviating pain and inflammation in arthritic conditions, but when given in high doses, severe GI problems develop in approximately 20% of patients.

Some pharmaceutical companies have developed antiinflammatory and analgesic drugs that inhibit only COX-2. The COX-2 inhibitors were developed to eliminate the GI side effects associated with aspirin and other NSAIDs. COX-2 inhibitors are discussed in depth in Chapter 25.

Side Effects and Adverse Reactions

A common side effect of NSAIDs is gastric irritation. These drugs should be taken with food, at mealtime, or with a full glass of fluid to help reduce this problem.

If an NSAID is taken for dysmenorrhea during the first 2 days of menstruation, excess bleeding might occur (more so with aspirin than with ibuprofen).

Some patients are hypersensitive to aspirin. Tinnitus, vertigo, bronchospasm, and urticaria are some of the symptoms that indicate hypersensitivity or overdose of the salicylate product. Certain foods also contain salicylates: prunes, raisins, paprika, and licorice. Those with a hypersensitivity to aspirin and salicylate products may be sensitive to other NSAIDs. This hypersensitivity may be related to inhibition of the enzyme cyclooxygenase by the salicylate product.

Acetaminophen

The analgesic acetaminophen (paraaminophenol derivative) is a popular nonprescription drug for the relief of pain, discomfort, and fever in infants, children, adults, and older adults. Acetaminophen is a nonopioid drug, but it is not an NSAID. Acetaminophen does not have the antiinflammatory properties of aspirin, so it is not the drug of choice for any inflammatory process. It constitutes 25% of all OTC drugs sold. Examples of OTC products that contain acetaminophen include Anacin; Excedrin; Midol: Maximum Strength Menstrual Formula; and Vicks: Cold & Flu Relief. Examples of prescription products on the market that contain acetaminophen include Lortab, Percocet, and Vicodin. Acetaminophen (Tylenol), first marketed in the mid-1950s, is an analgesic and antipyretic drug used for muscular aches and pains and for fever caused by viral infections. It is a safe, effective drug when used at therapeutic doses. It causes little to no gastric distress and does not interfere with platelet aggregation. An IV formulation was FDA approved in 2010 for treating pain and fever. There is no link between acetaminophen and Reye's syndrome, and it does not increase the potential for excessive bleeding if taken for dysmenorrhea, as do aspirin and NSAIDs (Prototype Drug Chart 26-1).

Pharmacokinetics Acetaminophen is well absorbed from the gastrointestinal (GI) tract. Rectal absorption may be erratic because of the presence of fecal material or a decrease in blood flow to the colon. Because of acetaminophen's short half-life, it can be administered every 4 hours as needed with a maximum dose of 4 g/day. However, it is suggested that a patient who frequently takes acetaminophen limit the dose to 2000 mg/day (2 g/day) to avoid the possibility of hepatic or renal dysfunction. More than 85% of acetaminophen is metabolized to drug metabolites by the liver.

PROTOTYPE DRUG CHART 26-1

Acetaminophen

Drug Class
Analgesic
Trade Names: Anacin-AF, Ofirmev
Pregnancy Category: B

Dosage
A: PO: 325-650 mg q4-6h PRN; *max:* 4000 mg/d; rectal supp: 650 mg q.i.d.
A: IV: 1 g q6h or 650 mg q4h PRN; *max:* 4 g/d
C >2 y: PO: 15 mg/kg q6h; *max:* 75 mg/kg/d

Contraindications
Acetaminophen hypersensitivity, severe hepatic or renal disease, alcoholism

Drug-Lab-Food Interactions
Increase effect with caffeine, diflunisal
Decrease effect with oral contraceptives, antacids, anticholinergics, cholestyramine, charcoal

Pharmacokinetics
Absorption: PO: Rapidly absorbed; rectal: erratic
Distribution: PB: 10%-25%; crosses the placenta, excreted in breast milk
Metabolism: $t\frac{1}{2}$: 2-4 h
Excretion: In urine as metabolites

Pharmacodynamics
PO: Onset: 10-30 min
Peak: 30-60 min
Duration: 3-5 h
Rectal: Onset: UK
Peak: UK
Duration: 4-6 h

Therapeutic Effects/Uses
To decrease pain and fever
Mode of Action: Inhibition (weak) of prostaglandin synthesis, inhibition of hypothalamic heat-regulator center

Side Effects
Anorexia, nausea, vomiting, rash, insomnia

Adverse Reactions
Oliguria, urticaria, elevated liver enzymes, hypoglycemia
Life-threatening: Hemorrhage, hepatotoxicity, hemolytic anemia, agranulocytosis, leukopenia, thrombocytopenia

A, Adult; *C,* child; *d,* day; *h,* hour; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t ½,* half-life; *UK,* unknown; *y,* year; <, less than; >, greater than.

Large doses or overdoses can be toxic to the hepatic cells, so when large doses are administered over a long period, the serum level of acetaminophen should be monitored. The therapeutic serum range is 10 to 25 mcg/mL. Liver enzyme levels (aspartate aminotransferase [AST], alanine aminotransferase [ALT], alkaline phosphatase [ALP]) and serum bilirubin should also be monitored. Large doses of acetaminophen with regular alcohol intake may lead to liver injury. When acetaminophen toxicity occurs, acetylcysteine (Mucomyst) is the antidote, which reduces liver injury by converting toxic metabolites to a nontoxic form.

Pharmacodynamics Acetaminophen weakly inhibits prostaglandin synthesis, which decreases pain sensation. It is effective in eliminating mild to moderate pain and headaches and is useful for its antipyretic effect. Acetaminophen does not possess antiinflammatory action. Its onset of action is rapid, and the duration of action is 5 hours or less. Severe adverse reactions may occur with an overdose, so acetaminophen in liquid or chewable form should be kept out of children's reach.

Side Effects and Adverse Reactions

An overdose of acetaminophen can be extremely toxic to liver cells, causing hepatotoxicity. Death could occur in 1 to 4 days from hepatic necrosis. If a child or adult ingests excessive amounts of acetaminophen tablets or liquid, a poison control center should be contacted immediately and the child or adult should be taken to the emergency department. Early symptoms of hepatic damage include nausea, vomiting, diarrhea, and abdominal pain.

Table 26-2 lists the commonly used nonopioid analgesics and their dosages, uses, and considerations.

Nursing Process
Patient-Centered Collaborative Care

Analgesic: Acetaminophen

Assessment
- Obtain a medical history of liver dysfunction. Overdosing or extremely high doses of acetaminophen can cause hepatotoxicity.
- Ascertain the severity of pain. Nonopioid NSAIDs such as ibuprofen or an opioid may be necessary to relieve pain.

Nursing Diagnoses
- Risk for injury related to analgesic effect on sensorium
- Acute pain related to edema from surgical incision

Planning
- Patient's pain will be relieved or diminished.

Nursing Interventions
- Check liver enzyme tests such as alanine aminotransferase, alkaline phosphatase, gamma-glutamyl transferase, 5′ nucleotidase, and bilirubin for elevations in patients taking high doses or overdoses of acetaminophen.

Patient Teaching
General
- Teach patient to keep acetaminophen out of children's reach. Acetaminophen for children is available in flavored tablets and liquid. High doses can cause hepatotoxicity.
- Advise patient not to self-medicate with acetaminophen longer than 10 days. Teach adult caregiver not to medicate child longer than 5 days without health care provider's approval.
- Direct parent to call poison control center immediately if a child has taken a large or unknown amount of acetaminophen.
- Teach patient to check acetaminophen dosage on package label of OTC drugs. Do not exceed the recommended dosage. Suggested safe adult acetaminophen dose is 2000 mg/d (2 g/day), not to exceed 4 g/day to avoid liver damage (see Prototype Drug Chart 26-1).

Side Effects
- Encourage patient to report side effects. Overdosing can cause severe liver damage and death.
- Inform patient that liver damage may occur with excess use of acetaminophen.
- Check serum acetaminophen level if toxicity is suspected. Normal serum level is 5 to 20 mcg/mL; toxic level is >50 mcg/mL. Levels of >200 mcg/mL could indicate hepatotoxicity. The antidote for acetaminophen is acetylcysteine (Mucomyst). Dosage is based on serum acetaminophen level.

Cultural Considerations
- Involving the extended family may be important for teaching health strategies and providing support.

Evaluation
- Evaluate the effectiveness of acetaminophen in relieving pain. If pain persists, another analgesic may be needed.
- Determine if patient is taking dose as recommended. Observe and report any side effects.

HERBAL ALERT 26-1
Capsaicin

Capsaicin, which is found naturally in cayenne pepper, is selective for C fiber nociceptors and relieves some arthritis pain in topical cream or gel form.

OPIOID ANALGESICS

Opioid analgesics, called **opioid agonists,** are prescribed for moderate and severe pain. In the United States, the Harrison Opioid Act of 1914 required that all forms of opium be sold with a prescription and that it no longer be used as a nonprescription drug. The Controlled Substances Act of 1970

TABLE 26-2 ANALGESICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Paraaminophenol		
acetaminophen	See Prototype Drug Chart 26-1.	
NSAIDs		
aspirin (Bayer, Ecotrin)	Analgesic: A: PO/PR: 325 to 650 mg, q4h; *max:* 4 g/d C: PO/PR: 10-15 mg/kg/d q4-6h; *max:* 4 g/d	Effective in relieving headaches, muscle pain, inflammation and pain from arthritis; mild anticoagulant. Can displace other highly protein-bound drugs. If taken with acetaminophen, GI bleeding could result. Side effects: gastric discomfort, tinnitus, vertigo, deafness (reversible), increased bleeding. Should be taken with foods or at mealtime. Should not be taken with alcohol. Pregnancy category: D; PB: 80%-90%; t½: 15-20 min
diflunisal (Dolobid)	A: PO: Initially 1000 mg; *maint:* 500 mg q12h; *max:* 1500 mg/d Older adults: PO: Initially 500 mg; *maint:* 250 q8-12h; *max:* 1500 mg/d	Used for mild to moderate pain. Considered to be less toxic than aspirin. Pregnancy category: C; PB: 99%, t½: 8-12 h
Propionic Acid		
ibuprofen (Motrin, Advil) ibuprofen: IV injection (Caldolor)	Pain: A: PO: 400 mg q4-6h; *max:* 3200 mg/d A: IV: 400-800 mg over 30 min q6h Fever: A: IV: 400 mg over 30 min q4-6h PRN	For mild to moderate muscle aches and pains. Causes some gastric distress but less than aspirin. Should be taken with food, at mealtime, or with plenty of fluids. Pregnancy category: C (D, third trimester); PB: 90%-99%; t½: 2-4 h
naproxen (Naprosyn)	Mild to moderate pain: A: PO: initially 500 mg, then 250 mg q6-8h; *max:* 1250 mg/d	Treatment of inflammation and pain from osteoarthritis, rheumatoid arthritis, ankylosing spondylitis, gout, and dysmenorrhea. Pregnancy category: C; PB: 99%; t½: 12-17 h
ketorolac (Toradol)	A: PO: 10 mg q6h PRN; *max:* 40 mg/d Older adults: PO: 10 mg q4-6h PRN; *max:* 40 mg/d A: IM/IV: 30-60 mg q6h PRN; *max:* 120 mg/d Older adults: IM/IV: 15 mg q6h PRN; *max:* 60 mg/d	For short-term pain management (5 days or less). Pregnancy category: C; PB: 99%; t½: 2.5-9 h
Oxicams		
meloxicam (Mobic)	A: PO: Initially 7.5-15 mg/d; *max:* 15 mg/d	Treatment of pain from osteoarthritis. Pregnancy category: C (first and second trimester), D (third trimester); PB: 99%; t½: 15-20 h
Naphthylalkanones		
nabumetone (Relafen)	A: PO: 1000 mg/d or 500 mg b.i.d.; *max:* 2000 mg/d	Treatment of pain from osteoarthritis, rheumatoid arthritis. Pregnancy category: C (D, third trimester); PB: 99%; t½: 24 h
COX-2 Inhibitors		
celecoxib (Celebrex)	A: PO: 100-400 mg b.i.d.; *max:* 800 mg/d Older adults: 100-200 mg b.i.d.; *max:* 400 mg/d	Treatment of osteoarthritis and rheumatoid arthritis. Not indicated for patients <18 y. Use caution for patients with severe renal or liver disorders and for those allergic to sulfonamides. Pregnancy category: C (D, third trimester); PB: 97%; t½: 11.2 h
Miscellaneous		
tramadol (Ultram) tramadol ER (Ultram ER, Ryzolt)	A: PO: Initially: 25 mg/d, *maint:* 50-100 mg q4-6h PRN; *max:* 400 mg/d A >75 y: *max:* 300 mg/d A: PO: ER: 100 mg/d; *max:* 300 mg/d	Used for moderate to severe pain. Contraindicated in severe alcoholism or with use of opioids. Nausea, vomiting, dizziness, constipation, headache, anxiety, and seizures may occur. Pregnancy category: C; PB: 20%; t½: 6.3 h for immediate release, 7.9 h for ER

A, Adult; *b.i.d.,* twice a day; *C,* child; *d,* day; *ER,* extended-release; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *min,* minute; *NSAIDs,* nonsteroidal antiinflammatory drugs; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *t½,* half-life; *UK,* unknown; *y,* year; >, greater than; <, less than.

classified addicting drugs, opioids among them, in five schedule categories according to their potential for drug abuse (see Chapter 9). **Addiction** is defined as a psychological and physical dependence upon a substance beyond normal voluntary control, usually after prolonged use of a substance.

HERBAL ALERT 26-2

Opioids

Opioids taken with kava kava, valerian, and St. John's wort may increase sedation.

Morphine, a prototype opioid, is obtained from the sap of seed pods of the opium poppy plant. Codeine is another drug obtained from opium. In the past decades, many synthetic and semisynthetic opioids have been developed.

While nonopioid analgesics act on the peripheral nervous system at the pain receptor sites, opioid analgesics act mostly on the CNS. Opioids act primarily by activating the μ receptors, while also exerting a weak activation of the kappa (κ) receptors. Analgesia, respiratory depression, euphoria, and sedation are effects of μ activation. Activation of κ receptors leads to analgesia and sedation, having no effect on respiratory depression and euphoria.

Opioids not only suppress pain impulses but also respiration and coughing by acting on the respiratory and cough centers in the medulla of the brainstem. One example of such an opioid is morphine, a potent analgesic that can readily depress respirations. Codeine is not as potent as morphine (1/15 to 1/20 as potent), but it also relieves mild to moderate pain and suppresses cough, which allows it also to be classified as an antitussive. Most opioids, with the exception of meperidine (Demerol), have an antitussive (cough suppression) effect. The opioids have two isomers, levo and dextro. The levo-isomers of opioids produce an analgesic effect only; however, both levo- and dextro-isomers possess an antitussive response. The dextro-isomers do not cause physical dependence, but the levo-isomers do. Synthetic cough suppressants are discussed in Chapter 40.

In addition to pain relief and antitussive effects, many opioids possess antidiarrheal effects. Common side effects with high doses of most opioids include nausea and vomiting (particularly in ambulatory patients), constipation, a moderate decrease in blood pressure, and orthostatic hypotension. High doses of opioids may also cause respiratory depression, urinary retention (usually in older adults), and antitussive effects.

Morphine

Morphine, an extraction from opium, is a potent opioid analgesic (Prototype Drug Chart 26-2). Morphine is effective against acute pain resulting from acute myocardial infarction (AMI), cancer, and dyspnea resulting from pulmonary edema. It may be used as a preoperative medication. Although it is effective in relieving severe pain, it can cause respiratory depression, orthostatic hypotension, miosis, urinary retention, constipation resulting from reduced bowel motility, and cough suppression. An antidote for morphine excess or overdose is the opioid antagonist naloxone (Narcan).

Pharmacokinetics Morphine may be taken orally, although GI absorption can be somewhat erratic. For severe pain, such as with AMI, it is given intravenously (IV). Morphine is 30% protein-bound and may also be administered rectally and epidurally. Oral morphine undergoes first hepatic pass, meaning the liver metabolizes the drug before bioavailability to the rest of the body occurs. Only a small amount of morphine crosses the blood-brain barrier to produce an analgesic effect. It has a short half-life, and 90% is excreted in the urine. Morphine crosses the placenta and is excreted in breast milk.

Pharmacodynamics Morphine binds with the opiate receptor in the CNS. Parenterally the onset of action is rapid, especially IV. Onset of action is slower for subcutaneous (subQ) and intramuscular (IM) injections. Duration of action with most types of drug administration is 3 to 5 hours; with controlled-release morphine sulfate tablets (MS Contin), duration is 8 to 12 hours.

Nursing Process

Patient-Centered Collaborative Care

Opioid Analgesic: Morphine Sulfate

Assessment

- Obtain a medical history. Contraindications for morphine include severe respiratory disorders, increased intracranial pressure, and severe renal disease. Morphine may cause seizures.
- Determine a drug history. Report if a drug-drug interaction is probable. Morphine increases the effects of alcohol, sedatives or hypnotics, antipsychotic drugs, and muscle relaxants and might cause respiratory depression.
- Assess vital signs, noting rate and depth of respirations for future comparisons; opioids commonly decrease respirations and systolic blood pressure.
- Monitor urinary output; morphine can cause urinary retention.
- Assess type of pain, location, and duration before giving opioids.

Nursing Diagnoses

- Acute pain related to surgical tissue injury
- Ineffective breathing patterns related to excess morphine dosage
- Risk for falls related to sedative effects secondary to morphine
- Constipation related to morphine

Planning

- Patient's pain will be diminished or alleviated.

Nursing Interventions

- Administer morphine before pain reaches its peak to maximize effectiveness of the drug.

PROTOTYPE DRUG CHART 26-2

Morphine Sulfate

Drug Class
Opioid
Trade Names: MS Contin, Roxanol
CSS II
Pregnancy Category: C/D

Dosage
A: PO: 10-30 mg q4h PRN
C >6 mo: PO: 0.2-0.5 mg/kg q4-6h PRN
Infants <6 mo/neonates: PO: 0.1 mg/kg q3-4h
A: SR: 15-30 mg, q12h PRN
A: IV/IM/subQ: 2.5-15 mg q2-6h PRN
C >6 mo: IM/subQ: 0.05-0.2 mg/kg q2-4h PRN; *max:* <15 mg/dose
Neonate: subQ/IM/IV: 0.05 mg/kg q4-8h

Contraindications
Hypersensitivity, CNS or respiratory depression, status asthmaticus, increased intracranial pressure, shock, alcoholism, ileus, hypovolemia
Caution: Respiratory, renal, or hepatic diseases; urinary retention, sleep apnea; older adults; very young

Drug-Lab-Food Interactions
Drug: Increase effects of alcohol, sedative-hypnotics, antipsychotic drugs, muscle relaxants
Lab: Increase AST, ALT

Pharmacokinetics
Absorption: PO: varies; IV: rapid
Distribution: PB: UK; crosses placenta, excreted in breast milk
Metabolism: $t\frac{1}{2}$: 1.5-2 h
Excretion: 90% in urine

Pharmacodynamics
PO: Onset: Variable
Peak: 1 h
Duration: 4-5 h; SR: 8-12 h
subQ/IM: Onset: 15-30 min
Peak: 50-90 min
Duration: UK
IV: Onset: rapid
Peak: 20 min
Duration: 3-5 h

Therapeutic Effects/Uses
To relieve severe pain
Mode of Action: Depression of the CNS; depression of pain impulses by binding with the opiate receptor in the CNS

Side Effects
Anorexia, nausea, vomiting, constipation, drowsiness, dizziness, sedation, confusion, urinary retention, rash, blurred vision, bradycardia, flushing, euphoria, pruritus

Adverse Reactions
Hypotension, urticaria, seizures, ileus
Life-threatening: Respiratory depression, increased intracranial pressure

A, Adult; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *C,* child; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *min,* minute; *PB,* protein binding; *PO,* by mouth; *PRN,* as necessary; *subQ,* subcutaneous; *SR,* sustained-release; $t\frac{1}{2}$, half-life; *UK,* unknown; <, less than.

- Monitor vital signs at frequent intervals to detect respiratory changes. Respirations of <10/min can indicate respiratory distress.
- Record patient's urine output because urinary retention is a side effect of morphine. Urine output should be at least 600 mL/day.
- Check bowel sounds for decreased peristalsis; constipation is a side effect of morphine. Dietary change or mild laxative might be needed.
- Check for pupil changes and reaction. Pinpoint pupils can indicate morphine overdose.
- Have naloxone (Narcan) available as an antidote to reverse respiratory depression if morphine overdose occurs.
- Validate dose of morphine before its administration. Check older adults for alertness and orientation because confusion is a side effect of morphine. Use side rails, and take other safety precautions as necessary.

Patient Teaching

General

- Encourage patient not to use alcohol or CNS depressants with any opioid analgesics such as morphine. Respiratory depression can result.
- Suggest nonpharmacologic measures to relieve pain as patient recuperates from surgery. As recovery progresses, a nonopioid analgesic may be prescribed.

Side Effects

- Alert patient that with continuous use, opioids such as morphine can become addicting. If addiction occurs, inform patient about methadone treatment programs and other resources in the area.
- Encourage patient to report dizziness while taking morphine. Dizziness could be due to orthostatic hypotension. Advise patient to ambulate with caution or only with assistance.

- Teach patient to report difficulty in breathing, blurred vision, and headaches.

Cultural Considerations

- Identify conflicts in values and beliefs about pain and its management.
- Respect cultural and religious differences concerning refusal of opioid analgesics.
- Incorporate traditional practices into Western medicine when possible.

Evaluation

- Evaluate the effectiveness of morphine in lessening or alleviating pain. If pain persists after several days, dose should be increased or opioid changed.
- Determine stability of vital signs. Any decrease in respiration and blood pressure should be reported.

Meperidine

One of the first synthetic opioids, meperidine (Demerol) became available in the mid-1950s. It is classified as a schedule II drug according to the Controlled Substances Act. Meperidine has a shorter duration of action than morphine, and its potency varies according to the dosage. Meperidine, which can be given orally, IM, and IV, is primarily effective in GI procedures. It does not have the antitussive property of opium preparations.

During pregnancy, meperidine is preferred to morphine because it does not diminish uterine contractions and causes less neonatal respiratory depression. Meperidine causes less constipation and urinary retention than morphine. Meperidine is not indicated for patients with chronic pain, severe liver dysfunction, sickle cell disease, a history of seizures, severe coronary artery disease (CAD), or cardiac dysrhythmias. When older adults and patients with advanced cancer receive large doses of meperidine, neurotoxicity (e.g., nervousness, tremors, agitation, irritability, seizures) have been reported. Meperidine should not be prescribed for long-term use; the dose is frequently limited to 600 mg in a 24-hour period for no longer than 48 to 72 hours.

Meperidine is metabolized in the liver to an active metabolite; therefore the dose should be decreased for patients with hepatic or renal insufficiency. It is excreted in the urine in a metabolite form called normeperidine. Meperidine should not be taken with alcohol or sedative-hypnotics, because the combination of these drugs causes an additive CNS depression. A major side effect of meperidine is a decrease in blood pressure, which should be monitored, especially if the patient is an older adult.

Table 26-3 lists opioids and their dosages, uses, and considerations.

SAFETY: Preventing Medication Errors

Do not confuse…

- **Meperidine** with **morphine**, **meprobamate**, or **hydromorphone**
- **Demerol** with **Desyrel**, **Dilaudid**, or **Temaril**

Hydromorphone

Hydromorphone (Dilaudid) is a semisynthetic opioid similar to morphine. The analgesic effect is approximately six times more potent than morphine with fewer hypnotic effects and less GI distress. This opioid has a faster onset and shorter duration of action than morphine. Hydromorphone is classified as a schedule II drug according to the Controlled Substances Act. Tolerance to hydromorphone increases gradually.

This drug is given orally, rectally, subQ, IM, and IV for the relief of moderate to severe pain. When given IV, dilution of each dose with 5 mL of sterile water or normal saline is preferred. Direct IV administration of 2 mg or less should be given over 2 to 5 minutes. Hydromorphone is readily absorbed in the body and excreted in the urine. Respirations should be monitored closely, and adequate hydration should be provided.

Side Effects and Adverse Reactions

Many side effects are known to accompany the use of opioids. Of particular importance are signs of respiratory depression (respiration <10/min). Other side effects include **orthostatic hypotension** (decrease in blood pressure when rising from a sitting or lying position), tachycardia, drowsiness and mental clouding, constipation, and urinary retention. In addition, pupillary constriction (a sign of toxicity), tolerance, and psychological and physical dependence may occur with prolonged use.

Increased metabolism of opioids contributes to tolerance, which causes an increased need for higher doses of the opioid. If chronic use of the opioid is discontinued, withdrawal (cessation of drug administration) symptoms usually occur within 24 to 48 hours after the last opioid dose. **Withdrawal syndrome** is caused by physical dependence. Symptoms of withdrawal syndrome include irritability, diaphoresis (sweating), restlessness, muscle twitching, and an increase in pulse rate and blood pressure. Withdrawal symptoms from opioids are unpleasant but not as severe or life-threatening as those that accompany withdrawal from sedative-hypnotics—a process that may lead to convulsions.

Contraindications

Use of opioid analgesics is contraindicated for patients with head injuries. Opioids decrease respiration, thus causing an accumulation of carbon dioxide (CO_2). With an increase in carbon dioxide retention, blood vessels dilate (vasodilation), especially cerebral vessels, which causes increased intracranial pressure.

Opioid analgesics given to a patient with a respiratory disorder only intensify the respiratory distress. In the patient with asthma, opiates decrease respiratory drive while simultaneously increasing airway resistance.

Opioids may cause hypotension and are not indicated for patients in shock or for those who have very low blood pressure. If an opioid is necessary, the dosage needs to be adjusted accordingly; otherwise, the hypotensive state may worsen. For an older adult or a person who is debilitated, the opioid dose usually needs to be decreased.

TABLE 26-3 OPIOIDS: OPIUM AND SYNTHETICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
codeine sulfate, codeine phosphate) CSS II	A: PO/subQ/IM: 15-60 mg q4-6h PRN; *max:* 360 mg/d C: PO/subQ/IM: 0.5-1 mg/kg q4-6h, *max:* 60 mg/dose	Effective for mild to moderate pain and as an antitussive. Can be used with nonopioids (acetaminophen) for pain relief. Can cause decreased respirations, constipation, and physical dependence. Pregnancy category: C/D; PB: 7%, $t_{1/2}$: 2.5-4 h
hydrocodone bitartrate (Hycodan) CSS II combination with acetaminophen (Lortab, Vicodin), aspirin (Lortab ASA), ibuprofen (Vicoprofin), and chlorpheniramine (Tussionex)	Analgesic: A: PO: 5 mg q4-6h PRN; *max:* 30 mg/d C >6 y: PO: 2.5 mg q4-6h PRN; *max:* 15 mg/d	For moderate to moderately severe pain. Used for antitussive purposes. Pregnancy category: C/D; PB: UK; $t_{1/2}$: 4 h
hydromorphone HCl (Dilaudid) CSS II	A: PO: 2.5-10 mg q4-6h PRN A: IV: 0.2-1 mg q2-3h PRN Rectal: 3 mg q6-8h	For moderate to severe pain. Can be prescribed for analgesic and antitussive purposes. Pregnancy category: C; PB: 8%-19%; $t_{1/2}$: 2-3 h
levorphanol tartrate (Levo-Dromoran) CSS II	A: PO/IV: 1 mg q3-6h A: IM/subQ: 1-2 mg q6-8h PRN	For moderate to severe pain. Has side effects similar to morphine. Pregnancy category: B; PB: 40%; $t_{1/2}$: 11-16 h
meperidine (Demerol) CSS II	A: PO/subQ/IM/IV: 50-150 mg q3-4h PRN C: PO/subQ/IM/IV: 1-1.5 mg/kg q3-4h PRN; *max:* 150 mg q4h	For moderate to severe pain, GI procedures, and preoperative sedation. Pregnancy category: C/D; PB: 60%-80%; $t_{1/2}$: 3-5 h
morphine sulfate CSS II	See Prototype Drug Chart 26-2.	
oxycodone HCl (OxyContin) CSS II	A: PO: 5-10 mg q6h PRN C >12 y: PO: 2.5 mg q6h PRN C 6-12 y: PO: 1.25 mg q6h PRN	For moderate to moderately severe pain, including postoperative and postpartum pain. Avoid taking drug over an extended period of time. As potent as morphine. Take with food to avoid GI distress. Pregnancy category: B (D in third trimester); PB: 40%; $t_{1/2}$: 3-5 h
oxycodone HCl with acetaminophen (Percocet) and oxycodone terephthalate with aspirin (Percodan) CSS II	A: PO: 2.5-10 mg q4-6h PRN or 5-10 mg q6h PRN	For moderate to severe pain. Percocet contains acetaminophen. Percodan contains aspirin and can cause gastric irritation, so it should be taken with food or plenty of liquid. Pregnancy category: C; PB: UK; $t_{1/2}$: 4 h
alfentanil (Alfenta) CSS II	A: IV: 3-8 mcg/kg for surgery Continuous infusion: 0.25-1 mcg/kg/min Total dose: 3-40 mcg/kg	Opioid analgesic with rapid onset of action. May be used to induce anesthesia. Pregnancy category: C; PB: 92%; $t_{1/2}$: 90-111 min
fentanyl (Duragesic, Sublimaze) CSS II	A: IM: 50-100 mcg q1-2h PRN A: Sublimaze IM: 50-100 mcg q1-2h PRN A: Duragesic transdermal patch: Initially 25 mcg/h patch q3d	Short-acting potent opioid analgesic. May be used with short-term surgery. Drug available as a lozenge and transdermal patch for controlling chronic pain. Pregnancy category: C; PB: 80%-89%; $t_{1/2}$: 7 h IV; 17 h transdermal
sufentanil citrate (Sufenta) CSS II	Primary anesthetic: A: IV: 8-30 mcg/kg with 100% oxygen and muscle relaxant Adjunct to anesthesia: IV: 1-8 mcg/kg	Potent synthetic opioid; used as part of the balanced anesthesia group. May be used as a primary anesthetic. Pregnancy category: C; PB: 93%; $t_{1/2}$: 1-3 h
remifentanil (Ultiva) CSS II	A: IV: Postop: 0.025-0.2 mcg/min	Newest opioid analgesic. Rapid onset of action, short-acting duration (5-10 min). Can cause respiratory depression, hypotension, and bradycardia. Pregnancy category: C; PB: 70%; $t_{1/2}$: 3-10 min
methadone (Dolophine) CSS II	Pain: A: PO/subQ/IM: 2.5-10 mg q8-12h PRN	For moderate to severe acute pain. Similar to morphine but longer duration of action. Used in drug abuse programs. Helps alleviate craving for opioids. Peak action 30-60 min. Pregnancy category: C; PB: 85%-90%; $t_{1/2}$: 2-3 h

A, Adult; *C,* child; *CSS,* Controlled Substances Schedule; *GI,* Gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *maint;* maintenance; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PRN,* as necessary; *subQ,* subcutaneous; $t_{1/2}$, half-life; *UK,* unknown; *y,* year.

Morphine is the opioid analgesic prototype, and all other opioids are measured in comparison to morphine.

Combination Drugs

To treat moderate to severe pain, combination drugs of an NSAID and an opioid analgesic may be used. Examples are hydrocodone and ibuprofen (Vicoprofen), which is a combination of an NSAID and an opioid. Another combination for the treatment of mild to moderate pain is acetaminophen and codeine. Using a combination of drugs for pain helps to decrease drug dependency that may result from possible long-term use of an opioid agent.

Patient-Controlled Analgesia

Patient-controlled analgesia (PCA) is an alternative route for opioid administration for self-administered pain relief as needed. Usually a loading dose (e.g., 2 to 10 mg of morphine) is given initially to achieve pain relief. Then within predetermined safety limits, the patient controls administration of the opioid analgesic, depending on the amount of pain. To receive the opioid, the patient pushes a button on the PCA device, releasing a specific dose of analgesic (e.g., 1 mg morphine) into the IV line. The nurse titrates the opioid analgesic dose by regulating the time intervals (every several minutes) at which the drug can be received. A lockout mechanism on the electronically controlled infusion pump prevents the patient from constantly pushing the button and causing a drug overdose. The PCA device maintains a near-constant analgesic level, avoiding episodes of severe pain and oversedation. Morphine is used most often for PCA, but fentanyl (Sublimaze) and hydromorphone (Dilaudid) may also be given.

Transdermal Opioid Analgesics

Transdermal opioid analgesics provide a continuous "around-the-clock" pain control that is helpful to patients who suffer from chronic pain. The transdermal method is not useful for acute or postoperative pain. An example of a transdermal opioid analgesic is fentanyl (Duragesic), which is administered via a transdermal patch. This patch comes in various strengths—12.5, 25, 50, 75, and 100 mcg/h. Maximum serum fentanyl levels occur within 24 hours of when the patch is first applied. Fentanyl is also available for IM and IV use. Fentanyl is more potent than morphine. For older adults, the use of a lower fentanyl transdermal dose is usually suggested. The health care provider must exercise caution when prescribing fentanyl for patients who weigh less than 110 pounds.

Analgesic Titration

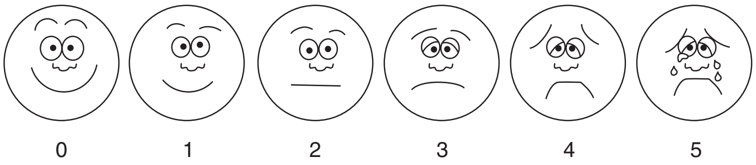
Analgesics may be titrated to increase or decrease the dosage. Usually postoperative pain will decrease over time, and analgesics will be titrated downward. However, the patient with cancer-related pain usually has a continual increase in pain and will require an upward titration. Titration can be accomplished by changing the dose, the interval between doses, the route of administration, or the drug. When titrating analgesics, the dosage is decided after assessing the patient's respiratory rate and pain level.

Opioid Use in Special Populations

Children

Pain management in children is complex, because it is more difficult to assess their pain. Some children will not verbalize discomfort when they are in severe pain, and some are fearful of treatments like injections that relieve pain. Nurses should use age-appropriate communication skills to ascertain a child's need for pain relief. The "ouch scale" illustrated in Figure 26-1 can be helpful in determining a child's level of pain. Also, the parent may help identify the presence and degree of the child's pain. Crying and whining may be indicators of a need for pain relief or may represent other needs.

A child, like an adult, should be given medication before the pain becomes severe. The use of oral liquid medication



1. Explain to the child that each face is for a person who feels happy because he has no pain (hurt, or whatever word the child uses) or feels sad because he has some or a lot of pain.
2. Point to the appropriate face and state, "This face is ..."
   0-"very happy because he doesn't hurt at all."
   1-"hurts just a little bit."
   2-"hurts a little more."
   3-"hurts even more."
   4-"hurts a whole lot."
   5-"hurts as much as you can imagine, although you don't have to be crying to feel this bad."
3. Ask the child to choose the face that best describes how he feels. Be specific about which pain (e.g., "shot" or incision) and what time (e.g., now? earlier? before lunch?).

FIGURE 26–1 A scale used to rate the intensity of pain in children. From Hockenberry M: *Wong's essentials of pediatric nursing,* ed. 9, St. Louis, 2013, Mosby.

for pain relief, if appropriate, is generally more acceptable to the child. The nurse may alleviate the child's fear and help with drug compliance by using drawings and pictures related to areas of pain in the body and pain relief with smiling faces.

Older Adults

Usually, adults who are 65 years of age or older require adjustment to drug doses to avoid severe side effects. Merely decreasing the usual adult dosage of opioid analgesic is not always the answer for older adults. Many take an array of medications for their health problems, increasing the possibility of drug interactions and drug side effects. In older adults, side effects from the use of opioids become more pronounced. The nurse needs to closely monitor for adverse reactions in older adults who take opioid analgesics. As a person ages, liver and renal functions decrease, causing the rate of metabolism and excretion of the drug to decrease. As a result, drug accumulation may occur.

Older adults tend to have different beliefs and fears than younger generations regarding opioids. They may believe that pain is inevitable due to aging or fear addiction. Older adults may not want to report pain, because they do not want to be a burden. The nurse must perform pain assessment with a supportive approach in an unhurried manner and teach the patient accurate drug information.

Pain assessment may be more difficult with older adults due to the decrease in cognitive and sensory-perceptual abilities. Dementia or hearing and visual deficits may interfere with communication. The nurse may need to rely on a more thorough physical assessment to discover the presence of pain, because self-reporting may not be reliable.

In the presence of decreased renal and hepatic function, drugs that tend to be more toxic in older adults include meperidine (Demerol), pentazocine (Talwin), and propoxyphene (Darvon). Analgesics are usually metabolized in the liver and excreted in the urine. Usual doses of analgesics in older adults may result in excessive sedation and prolonged duration of action. Chronologic age is one of several factors that influence medication use and dosage. Comorbidity must also be considered.

Cognitively Impaired Individuals

Any cognitively impaired individual may be unable to report pain adequately. The nurse should use a measurement scale that is appropriate for the patient. Some physical signs of pain include moans, grimacing, clenched teeth, noisy respirations, and restlessness.

Oncology Patients

Cancer pain is managed according to three levels of analgesia based on the World Health Organization (WHO) Ladder as follows:

Step 1—Mild Pain: Nonopioids with or without an adjuvant medication

Step 2—Moderate Pain: Nonopioids and mild opioid with or without an adjuvant medication

Step 3—Severe Pain: Stronger opioid at higher dosage levels with or without an adjuvant medication

Opioids are titrated for oncology patients until pain relief is achieved or the side effects become intolerable. For effective pain management in patients with cancer, extremely high doses may be required. There are no set dosage limits for oncology patients.

Individuals with a History of Substance Abuse

Often patients with a history of substance abuse require pain medication. A thorough pain assessment is necessary to find out the cause of pain. The nurse needs to know that opioids are effective and safe in this population, even though larger doses in greater frequency may be required. Studies have shown that withholding opioids in this population has not increased recovery from addiction. However, opioid agonist-antagonists such as pentazocine (Talwin) should be avoided in chemically dependent patients, because these drugs may precipitate withdrawal syndrome.

ADJUVANT THERAPY

Medications used as **adjuvant analgesics** have been developed for other purposes and later found to be effective for pain relief in neuropathy. Adjuvant therapy is usually used along with a nonopioid and opioid. Examples of adjuvant analgesics include anticonvulsants, antidepressants, corticosteroids, antidysrhythmics, and local anesthetics.

Anticonvulsant medications (gabapentin [Neurontin]) act on the peripheral nerves and CNS by inhibiting spontaneous neuronal firing. They are used for neuropathic pain and the prevention of migraine headaches. Tricyclic antidepressants (amitriptyline [Elavil]) prevent the reuptake of serotonin and norepinephrine in the cells. Lower doses of tricyclic antidepressants than those usually prescribed for depression are effective in treating peripheral neuropathy. Corticosteroids serve as effective analgesics by reducing nociceptive stimuli. Antidysrhythmics (mexiletine [Mexitil]) block sodium channels to reduce pain. Local anesthetics (lidocaine patch) can be effective analgesics by interrupting the transmission of pain signals to the brain.

Adjuvant medications potentiate opioid analgesia for severe persistent pain in diabetic neuropathy, cancer, migraine headaches, and rheumatoid arthritis. When any of the adjuvant medications are used in conjunction with an NSAID and opioid, dosages may be kept lower to reduce adverse effects.

TREATMENT FOR OPIOID-ADDICTED INDIVIDUALS

Refer to Chapter 5 for a discussion of therapies for addiction.

OPIOID AGONIST-ANTAGONISTS

Opioid agonist-antagonists, medications in which an opioid antagonist (e.g., naloxone [Narcan]) is added to an opioid agonist, were developed in hopes of decreasing opioid abuse. Pentazocine (Talwin), the first opioid analgesic, can be given orally (tablet) and by injection (subQ, IM, and IV). Pentazocine is classified as a schedule IV drug. Butorphanol tartrate (Stadol), buprenorphine (Buprenex), and nalbuphine hydrochloride (Nubain) are examples of other opioid agonist-antagonist analgesics. Reports say that pentazocine and butorphanol can cause dependence. Opioid agonist-antagonist drugs are not given for cancer pain, because of the risk of potential CNS toxicity from the high doses required. These analgesics are considered safe for use during labor, but their safety during early pregnancy has not been established.

Prototype Drug Chart 26-3 details the pharmacologic behavior of nalbuphine, and Table 26-4 lists the various opioid agonist-antagonists.

PROTOTYPE DRUG CHART 26-3

Nalbuphine

Drug Class

Opioid: agonist-antagonist
Trade Name: Nubain
Pregnancy Category: B/D

Dosage

A: IV/IM/subQ: 10-20 mg q3-6h; *max:* 160 mg/d

Contraindications

Hypersensitivity
Caution: History of drug abuse or emotional instability, impaired respirations, head injury, increased intracranial pressure, MI, biliary tract surgery, renal or hepatic dysfunction

Drug-Lab-Food Interactions

Drug: CNS depression is potentiated with alcohol or other CNS depressants

Pharmacokinetics

Absorption: readily occurs parenterally
Distribution: PB: <30%; crosses placenta, excreted in breast milk
Metabolism: $t_{1/2}$: 3-6 h
Excretion: In urine, bile, feces

Pharmacodynamics

Onset: 2-3 min IV; 15 minutes IM
Peak: 30 min IV; 30 min IM
Duration: 3-4 h IV; 3-6 h IM

Therapeutic Effects/Uses

To relieve moderate to severe pain
Mode of Action: Inhibition of pain impulses transmitted in the CNS by binding with opiate receptor and increasing pain threshold

Side Effects

Dizziness, confusion, hallucinations, blurred vision, headache, flushing, sedation, nervousness, restlessness, euphoria, depression, crying, dysphoria, unusual dreams, dry mouth, bitter taste, nausea, vomiting, abdominal cramps, clammy skin, urinary urgency

Adverse Reactions

Bradycardia, tachycardia, hypotension, hypertension, dyspnea
Life-threatening: Respiratory depression

CNS, Central nervous system; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *MI,* myocardial infarction; *min,* minute; *PB,* protein-binding; *subQ,* subcutaneous; $t_{1/2}$, half- life.

TABLE 26-4 OPIOIDS: AGONIST-ANTAGONISTS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
buprenorphine HCl (Buprenex) CSS V	Pain: A: IM/IV: Initially: 0.3 mg q4h PRN	For moderate to severe pain associated with surgery, cancer, urinary calculi, myocardial infarction, and trauma. Avoid alcohol and CNS depressants. Pregnancy category: C; PB: 96%; $t_{1/2}$: 2-37 h
butorphanol tartrate (Stadol) CSS IV	A: IM: 1-4 mg q3-4h PRN A: IV: 0.5-2 mg q3-4h PRN Nasal spray: 1 mg (1 spray) q3-4h	Management of moderate to severe pain associated with cancer, urinary calculi, labor, musculoskeletal, and burns. Pregnancy category: C; PB: 80%; $t_{1/2}$: 5 h
nalbuphine HCl (Nubain) CSS IV	See Prototype Drug Chart 26-3.	
pentazocine lactate (Talwin) CSS IV	A: PO: 50-100 mg q3-4h PRN; *max:* 600 mg/d A: subQ/IM/IV: 30 mg q3-4 h PRN; *max:* 360 mg/d	To control moderate to severe pain. Pregnancy category: C; PB: 60%; $t_{1/2}$: 1.5-10 h

A, Adult; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *subQ,* subcutaneous; $t_{1/2}$, half-life; *UK,* unknown; >, greater than.

Pharmacokinetics Nalbuphine can be administered orally, IM, subQ, or IV. It is rapidly absorbed parenterally. Nalbuphine has a short half-life. It is metabolized in the liver and excreted in the urine.

Pharmacodynamics Nalbuphine is effective in alleviating moderate to severe pain. Onset of action is rapid, and peak time occurs within 30 minutes with IV administration. Duration of action is the same for all routes of administration: approximately 5 hours.

SAFETY: Preventing Medication Errors

Do not confuse…

- **Nubain** (narcotic agonist-antagonist analgesic for moderate to severe pain) with **Nebcin** (aminoglycoside antibiotic) or **Nuprin** (OTC analgesic, antipyretic, NSAID).

Nursing Process
Patient-Centered Collaborative Care

Opioid Agonist-Antagonist Analgesic: Nalbuphine (Nubain)

Assessment

- Obtain a drug history from patient. Report if a drug-drug interaction is probable. When taken with nalbuphine, CNS depressants can cause respiratory depression.
- Note baseline vital signs for future comparison.
- Assess the type of pain, duration, and location before giving the drug.

Nursing Diagnosis

- Acute pain related to trauma
- Knowledge deficit related to unfamiliarity of drug

Planning

- Patient's intensity of pain will be lessened.

Nursing Interventions

- Monitor vital signs. Note any changes in respirations.
- Check bowel sounds and date of last bowel movement to identify constipation. Decreased peristalsis may result in constipation. A mild laxative may be necessary.
- Determine urine output. Report if urine output is <30 mL/h or <600 mL/day.
- Administer IV nalbuphine undiluted. Do not mix with barbiturates.

Patient Teaching

General

- Warn patient not to use alcohol or CNS depressants while taking nalbuphine. Respiratory depression can occur.
- Suggest nonpharmacologic methods for lessening pain like changing position or ambulation.

Side Effects

- Advise patient to report side effects of nalbuphine: dizziness, headaches, constipation, dysuria, rash, or blurred vision. Hallucinations, tachycardia, and respiratory depression are adverse reactions that might occur.

Cultural Considerations

- Accept various cultural groups' use of alternative methods in relief of pain.

Evaluation

- Evaluate effectiveness of nalbuphine in relieving pain. If ineffective, another opioid analgesic may need to be ordered.
- Determine stability of vital signs. Note if there is a change in respirations, pulse rate, or blood pressure. Report abnormal findings.

OPIOID ANTAGONISTS

Opioid antagonists are antidotes for overdoses of natural and synthetic opioid analgesics. The opioid antagonists have a higher affinity to the opiate receptor site than the opioid being taken. An **opioid antagonist** blocks the receptor and displaces any opioid that would normally be at the receptor, inhibiting the opioid action. Indications for opioid antagonists include reversal of postoperative opioid depression and opioid overdose.

Naloxone (Narcan), administered IM or IV; naltrexone hydrochloride (ReVia), administered orally by tablet or liquid; and nalmefene are opioid antagonists. These drugs are perfect examples of pharmacologic antagonists because they reverse the respiratory and CNS depression (sedation and hypotension) caused by opioids. Table 26-5 lists the opioid antagonists.

When receiving opioid antagonists, the patient should be monitored continuously. The opioid action may exceed that of opioid antagonists, and further analgesia may be needed. For example, fentanyl and a combination of drugs given during surgery may lead to excessive respiratory depression. Naloxone may be given as an opioid antidote. The patient's respiratory and CNS status should be monitored closely for indications of analgesic reversal (tachycardia, nausea, vomiting, and sweating) and possible need of further analgesia. The patient receiving naloxone should also be observed for bleeding, because this drug may cause an elevated partial thromboplastin time.

HEADACHES: MIGRAINE AND CLUSTER

Migraine headaches are characterized by a unilateral throbbing head pain accompanied by nausea, vomiting, and photophobia. These symptoms frequently persist for 4 to 24 hours and for several days in some cases. Two thirds of migraine headaches are experienced by women in their twenties and thirties. Symptoms usually decrease or are absent during pregnancy and menopause. The intensity of migraine pain can disrupt daily activities.

Pathophysiology

Migraine headaches are caused by inflammation and dilation of the blood vessels in the cranium. The etiology is unknown, but some theories suggest an imbalance in the neurotransmitter serotonin (5-hydroxytryptamine [5-HT]) that causes vasoconstriction and suppresses migraine headaches. The tendency of calcitonin gene-related peptide (CGRP) is to promote a migraine attack. Serum CGRP levels are elevated during a migraine attack. Foods such as cheese, chocolate, and red wine can trigger an attack.

The two types of migraine are (1) classic migraines, which are associated with an aura that occurs minutes to 1 hour before onset, and (2) common migraines, which are not associated with an aura.

Cluster headaches are characterized by a severe unilateral nonthrobbing pain usually located around the eye. They occur in a series of cluster attacks—one or more attacks every day for several weeks. They are not associated with an aura and do not cause nausea and vomiting. Men are more commonly affected by cluster headaches than women.

Treatment of Migraine Headaches

Preventive treatment for migraines includes (1) beta-adrenergic blockers such as propranolol (Inderal) and atenolol (Tenormin); (2) anticonvulsants such as valproic acid (Depakote) and gabapentin (Neurontin); and (3) tricyclic antidepressants such as amitriptyline (Elavil) and imipramine (Tofranil).

Treatment or cessation of a migraine attack depends on the intensity of pain. Drugs used to treat migraines include analgesics, opioid analgesics, ergot alkaloids, and selective serotonin$_1$ (5-HT) receptor agonists, also known as *triptans.* For mild migraine attacks, aspirin, acetaminophen, or NSAIDs, such as ibuprofen or naproxen (Aleve), may be prescribed. Aspirin may be used in combination with caffeine. Meperidine (Demerol) and butorphanol nasal spray (Stadol NS) are opioid analgesics that are occasionally used.

Antimigraine medication should be taken early during a migraine attack. Nausea and vomiting might occur; antiemetics decrease these symptoms. Dihydroergotamine, an ergot alkaloid, can be administered subcutaneously, intramuscularly, intravenously, and by means of a nasal spray.

The triptans (5-HT$_1$ receptor agonists) are the most recently developed group of drugs for the treatment of migraine headaches. Sumatriptan (Imitrex), a selective serotonin receptor agonist with a short duration of action, was the first triptan drug. It is considered more effective than ergot alkaloids in treating acute migraine attacks. Table 26-6 lists the ergot alkaloids and the selective serotonin$_1$ (5-HT) receptor agonists and their dosages, uses, and considerations. Do not confuse sumatriptan with zolmitriptan. Both drugs are triptans but have different dosages. Also, do not confuse Amerge (triptan used for migraines) with Amaryl (sulfonylurea used for diabetes mellitus) or Altace (angiotensin-converting enzyme inhibitor) used for hypertension and heart failure. Prototype Drug Chart 26-4 provides further pharmacology of sumatriptan.

TABLE 26-5 **OPIOID ANTAGONISTS**

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
naloxone HCl (Narcan)	Opiate overdose or opioid-induced respiratory distress: A: IV: 0.4-2 mg; may repeat q2-3 min; *max:* 10 mg C: IV: 0.01-0.1 mg/kg; may repeat q2-3 min; *max:* 10 mg	To treat opioid overdose. Approved for use in neonates to reverse respiratory depression induced by maternal opioid use. Pregnancy category: B; PB: UK; t½: 0.5-1.5 h
naltrexone HCl (Vivitrol, ReVia)	A: PO: 25 mg/d; repeat 25 mg in 1 h if no withdrawal response; *max:* 150 mg/d A: IM: 380 mg/dose q4wk; *max:* 380 mg/dose	To treat opioid and alcohol abuse. Three to five times more potent than naloxone. Decreases but does not prevent craving for opioids. Use after patient is off opioids for 7 days or more. Do not give if patient is in opiate withdrawal; can precipitate a withdrawal reaction. High doses can cause hepatotoxicity. Pregnancy category: C; PB: 21%-28%; t½: 5-10 h

A, Adult; *C,* child; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *t½,* half-life; *UK,* unknown.

TABLE 26-6 **DRUGS USED TO TREAT SEVERE MIGRAINE HEADACHES**

DRUG	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Ergot Alkaloids		
dihydroergotamine mesylate (Migranal)	A: Intranasal: 1 spray in each nostril; may repeat in 15 min; *max:* 4 sprays (2 mg)/attack, 8 sprays/d, 24 sprays/wk A: IM/IV: 1 mg; may repeat in 1 h; *max:* 6 mg/wk	To prevent or abort migraine attack. Pregnancy category: X; PB: 90%-93%; t½: 21-32 h

TABLE 26-6 DRUGS USED TO TREAT SEVERE MIGRAINE HEADACHES—cont'd

DRUG	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Selective Serotonin$_1$ Receptor Agonists (Triptans)		
sumatriptan (Imitrex)	See Prototype Drug Chart 26-4.	
naratriptan (Amerge)	A: PO: 1-2.5 mg; may repeat in 4 h; *max:* 5 mg/d	For acute migraines. Has a longer half-life, thus duration of action is longer. Causes vasoconstriction of cranial arteries. Avoid if patient has uncontrolled hypertension, IHD, prior MI. Pregnancy category: C; PB: 28%-31%; t½: 6 h
rizatriptan benzoate (Maxalt)	A: PO: 5-10 mg; may repeat in 2 h; *max:* 30 mg/d	For acute migraines. Two types of tablets: regular and melt-in-mouth. Avoid if patient has uncontrolled hypertension, IHD, prior MI. Pregnancy category: C; PB: 14%; t½: 2-3 h
zolmitriptan (Zomig)	A: PO: 2.5-5 mg; may repeat in 2 h; *max:* 10 mg/d	For acute migraines. 65% of patients respond in 2 h. Avoid if patient has uncontrolled hypertension, IHD, prior MI. Pregnancy category: C; PB: 25%; t½: 3 h
almotriptan (Axert)	A: PO: 6.25-12.5 mg; may repeat in 2 h; *max:* 25 mg/d	For acute migraines. Pregnancy category: C; PB: 35%; t½: 3-4 h
frovatriptan (Frova)	A: PO: 2.5 mg; may repeat in 2 h; *max:* 7.5 mg/d	For acute migraines. Pregnancy category: C; PB: 15%; t½: 26 h
eletriptan (Relpax)	A: PO: 20-40 mg; may repeat in 2 h; *max:* 80 mg/d	For acute migraines. Pregnancy category: C; PB: 85%; t½: 4-5 h

A, Adult; *h,* hour; *IHD,* ischemic heart disease; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *MI,* myocardial infarction; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *SL,* sublingual; *subQ,* subcutaneous; *t½,* half-life; *UK,* unknown, *wk,* week.

PROTOTYPE DRUG CHART 26-4

Sumatriptan

Drug Class
5-HT$_1$ receptor agonist: antimigraine
Trade Name: Imitrex
Pregnancy Category: C

Dosage
A: PO: 25-50 mg for 1 dose, may repeat once after 2 h, *max:* 200 mg/d
A: subQ: 6 mg, may repeat with 6 mg at least 1 h after first injection, *max:* 12 mg/d
A: Intranasal: 5-20 mg in one nostril, may repeat after 2 h, *max:* 40 mg/d

Contraindications
Hypersensitivity, coronary artery disease, peripheral vascular disease, hypertension, obesity, diabetes mellitus, smoking, hepatic disease, cerebrovascular disease, older adults
Caution: Renal dysfunction, seizures

Drug-Lab-Food Interactions
Drug: Risk of vasospasm and blood pressure elevation with dihydroergotamine and other ergot alkaloids; increased levels and toxicity within 2 weeks of MAOIs; increased risk of serotonin syndrome or neuroleptic malignant syndrome with SSRIs

Pharmacokinetics
Absorption: Rapidly absorbed following subQ injection
Distribution: PB: 14%-21%
Metabolism: t½: 2 h
Excretion: Urine and feces

Pharmacodynamics
PO: Onset: 60 min
Peak: 2 h
Duration: 24-48 h
subQ: Onset: 10 min
Peak: 1 h
Duration: 24-48 h
Intranasal: Onset: 15 min
Peak: 1-1.5 h
Duration: 24-48 h

Therapeutic Effects/Uses
To treat migraine and cluster headaches
Mode of Action: Causes vasoconstriction of cranial arteries to relieve migraine attacks

Side Effects
Dizziness, fainting, tingling, numbness, warm sensation, drowsiness, muscle cramps, nausea, vomiting, dry mouth, diarrhea, abdominal cramping

Adverse Reactions
Hypotension, hypertension, heart block, angina, dysrhythmias, thromboembolism, seizures, central nervous system hemorrhage, stroke
Life-threatening: Coronary artery vasospasm, myocardial infarction, cardiac arrest

A, Adult; *h,* hour; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *subQ,* subcutaneous; *t½,* half-life; *UK,* unknown.

CRITICAL THINKING CASE STUDY

RJ, a 79-year-old man, underwent abdominal surgery for resection of his colon. His physician prescribed morphine 10 mg every 3 to 4 hours PRN after the surgery. RJ did not ask for "pain medication," because he worried he might become addicted. A day after the surgery, his nurse noted that he was restless and grimaced whenever he moved in bed. He refused to breathe deeply or cough when instructed to do so. The nurse compared RJ's vital signs to his baseline findings and noted an increased pulse rate and a drop in systolic blood pressure of 6 mm Hg.

1. Should the nurse give morphine? Explain your answer.
2. What would your reaction be to RJ in regard to his restlessness, grimacing, and refusal to deep breathe and cough?
3. What is the significance of the change in vital signs?
4. What classic side effects of opioid analgesics should the nurse assess?
5. What are some possible nonpharmacologic measures that might be helpful in alleviating RJ's pain?

The second postoperative day, RJ began asking for morphine every 3 hours. On the fifth day, the physician discontinued RJ's morphine and prescribed acetaminophen with codeine.

6. Why was the opioid analgesic order changed?
7. RJ does not want to ambulate. What is an appropriate nursing response?

NCLEX STUDY QUESTIONS

1. A patient requires a nonopioid medication. The nurse knows that which medication will cause the least gastrointestinal distress?
   a. aspirin
   b. ketorolac
   c. celecoxib
   d. ibuprofen
2. A patient states during a medical history that he takes several acetaminophen tablets throughout the day. The nurse teaches the patient that the dosage should not exceed which amount?
   a. 1 g/day
   b. 2 g/day
   c. 4 g/day
   d. 6 g/day
3. For the patient receiving periodic morphine IV push, which is the most critical finding for the nurse to discover?
   a. Increased temperature
   b. Decreased bowel sounds
   c. Decreased respirations
   d. Increased red blood cell count
4. A patient is admitted to the emergency department in respiratory depression following self-injection with hydromorphone. The admitting nurse knows that which drug will reverse respiratory depression caused by opioid overdose?
   a. fentanyl
   b. naloxone
   c. butorphanol
   d. sufenta
5. Assessing a patient following IV morphine administration, the nurse notes cold, clammy skin; a pulse of 40 beats/min; respirations of 10 breaths/min; and constricted pupils. Which medication will the patient likely need next?
   a. naloxone (Narcan)
   b. meloxicam (Mobic)
   c. pentazocine (Talwin)
   d. propoxyphene (Darvon)
6. For the patient who is taking acetaminophen (Tylenol), what should the nurse do? (Select all that apply.)
   a. Monitor routine liver enzyme tests.
   b. Encourage the patient to check package labels of OTC drugs to avoid overdosing.
   c. Teach the diabetic patient taking acetaminophen to check blood glucose more frequently.
   d. Teach the female patient that oral contraceptives can increase the effect of acetaminophen.
   e. Teach the patient that caffeine decreases the effects of acetaminophen.
7. For the patient who is taking nalbuphine (Nubain), what should the nurse do? (Select all that apply.)
   a. Monitor any changes in respirations.
   b. Instruct the patient to report bradycardia.
   c. Administer IV nalbuphine undiluted.
   d. Explain to the patient to expect an excessive amount of urine output.
   e. Instruct the patient to avoid alcohol when taking nalbuphine to avoid respiratory depression.
8. A patient is having a migraine attack. The nurse should know that which drugs are used to treat migraine attacks?
   a. Triptans
   b. Anticonvulsants
   c. Tricyclic antidepressants
   d. Beta-adrenergic blockers

Answers: 1, c; 2, c; 3, c; 4, b; 5, a; 6, a, b, c; 7, a, b, c, e; 8, a.

UNIT VIII

Psychiatric Agents

From moods and emotions flow the various thoughts and actions of individuals, which are communicated throughout the central nervous system (CNS) by chemical neurotransmitters. An impulse is communicated by traveling through the presynaptic neuron across the synaptic cleft and binding to a receptor on the postsynaptic neuron, as illustrated in Figure VIII-1.

Neurotransmitters are synthesized in the cytoplasm in the presynaptic neuron and stored in vesicles. Vesicles safeguard neurotransmitters from being destroyed by enzymes. When an impulse arrives by way of an action potential at a presynaptic neuron, vesicles are triggered to move to the cell membrane wall and release the transmitter into the synaptic cleft.

Neurotransmitters function with the help of receptors, which are embedded in the membrane of the postsynaptic neuron. Receptors are configured in size and shape to interlock with specific transmitters. Immediately upon connection of neurotransmitters to receptors, an action is exerted and the transmitter is removed. Once released, transmitters can be broken down into inactive substances by enzymes, diffused away from the synapse into intracellular fluid, or returned to the presynaptic neuron in a process called *reuptake*.

The major neurotransmitters affecting psychopathology include gamma-aminobutyric acid (GABA), serotonin, dopamine, norepinephrine, and acetylcholine. The GABA neurotransmitter is associated with the regulation of anxiety. When the level of GABA neurotransmitters is reduced, anxiety disorders may result.

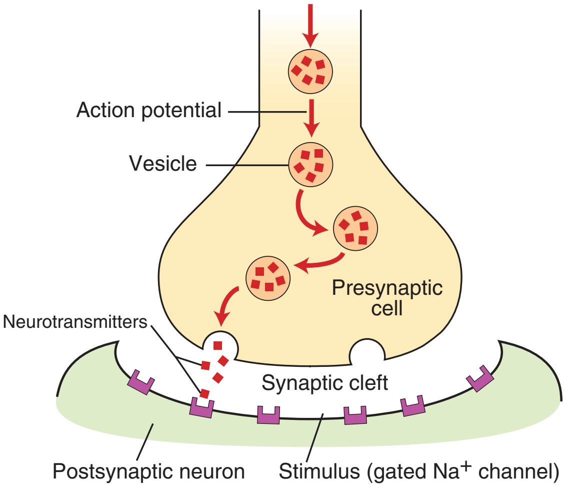

FIGURE VIII–1 Chemical neurotransmitters.

Benzodiazepines (antianxiety drugs) act by binding to a GABA receptor site, making the postsynaptic receptor more sensitive to GABA and its neurotransmission. This connection decreases the signs and symptoms of anxiety.

Serotonin neurotransmission is associated with arousal and general activity levels of the CNS. Serotonin functions to regulate sleep, wakefulness, and mood, as well as the delusions, hallucinations, and withdrawal of schizophrenia. Antidepressants block the reuptake of serotonin into the presynaptic neuron. A structurally specific drug is more likely to affect only the specific receptors for which it is intended and not the receptors specific for other neurochemicals, which would produce unintended effects. Selective serotonin reuptake inhibitor (SSRI) drugs are specific and generally produce fewer side effects in the treatment of depression than older antidepressants such as monoamine oxidase inhibitors (MAOIs).

Dopamine-containing neurons are thought to be involved in the regulation of cognition, emotional responses, and motivation, and dopamine neurotransmitters are associated with schizophrenia and other psychoses. Antipsychotic drugs block dopamine receptors in the postsynaptic neuron.

Norepinephrine is associated with control of arousal, attention, vigilance, mood, affect, and anxiety. This transmitter is involved with thinking, planning, and interpreting. Tricyclic antidepressants block the reuptake of norepinephrine into the presynaptic neuron and effectively treat depressive disorders. MAOIs inactivate norepinephrine, dopamine, and serotonin by inhibiting the monoamine oxidase enzyme to relieve signs and symptoms of depression.

Faulty release, reuptake, or elimination of neurotransmitters may lead to an imbalance of neurotransmission and pathology. Disorders can then develop that affect an individual's thoughts, feelings, and behaviors.

Knowledge of psychopharmacology is essential to psychiatric mental health nursing. A basic understanding of the actions of psychotropic drugs will help nurses rapidly comprehend and apply information and enhance the effectiveness of pharmacologic treatment. Essential responsibilities of the nurse in administering psychotropic medications are to assess behavior, monitor for side effects, and educate the patient and family. These actions are crucial to successful psychopharmacologic therapy.

Drugs used to treat psychoses and anxiety are discussed in Chapter 27. Antidepressants and mood stabilizers are discussed in Chapter 28.

OBJECTIVES

- Differentiate between the two groups of drugs: antipsychotics and anxiolytics.
- Contrast the action, uses, side effects, and adverse effects of traditional/typical and atypical antipsychotics.
- Plan nursing interventions, including patient teaching, for the patient taking antipsychotics and anxiolytics.
- Apply the nursing process to the patient taking an atypical antipsychotic, a typical antipsychotic, and an anxiolytic.

Antipsychotics and anxiolytics are CNS depressants used to manage symptoms of psychosis and anxiety disorders. Antipsychotics are also known as *neuroleptics* or *psychotropics,* but the preferred name for this group is either *antipsychotics* or *neuroleptics.* **Neuroleptic** refers to any drug that modifies psychotic behavior and exerts an antipsychotic effect. Anxiolytics are also called *antianxiety drugs* or *sedative-hypnotics.* Certain anxiolytics are used to treat sleep disorders, seizures, and withdrawal symptoms from alcohol or other abuse substances. Some of these drugs are also used for conscious sedation and anesthesia supplementation. However, the anxiolytics described in this chapter are used specifically to treat anxiety.

PSYCHOSIS

Psychosis, or losing contact with reality, is manifested in a variety of mental or psychiatric disorders. Psychosis is usually characterized by more than one symptom, but these may include difficulty in processing information and coming to a conclusion, delusions, hallucinations, incoherence, catatonia, and aggressive or violent behavior. **Schizophrenia,** a chronic psychotic disorder, is the major category of psychosis in which many of these symptoms are manifested.

The symptoms of schizophrenia usually develop in adolescence or early adulthood. The symptoms of this psychotic disorder are divided into two groups: "positive" symptoms and "negative" symptoms. Positive symptoms may be characterized by exaggeration of normal function (e.g., agitation), incoherent speech, hallucinations, delusions, and paranoia. Negative symptoms are characterized by a decrease or loss in function and motivation. There is a poverty of speech content, poor self-care, and social withdrawal. Negative symptoms tend to be more chronic and persistent. The typical or traditional group of antipsychotics is more helpful for managing positive symptoms than negative symptoms. A group of antipsychotics called *atypical* have been found to be more useful in treating both the positive and negative symptoms of schizophrenia. *Antipsychotics* compose the largest group of drugs used to treat mental illness. Specifically, these drugs improve the thought processes and behavior of patients with psychotic symptoms, especially those with schizophrenia and other psychotic disorders. They are not used to treat anxiety or depression. The theory is that psychotic symptoms result from an imbalance in the neurotransmitter **dopamine** in the brain. Sometimes these antipsychotics are called *dopamine antagonists.* Antipsychotics block D_2 dopamine receptors in the brain, reducing psychotic symptoms. Many antipsychotics block the chemoreceptor trigger zone and vomiting (emetic) center in the brain, producing an **antiemetic** (prevents or relieves nausea and vomiting) effect. When dopamine is blocked, however, **extrapyramidal symptoms (EPS)** of **parkinsonism** (Parkinson's disease, a chronic neurologic disorder that affects the extrapyramidal motor tract) such as tremors, masklike facies, rigidity, and shuffling gait may develop. Many patients who take high-potency antipsychotic drugs may require long-term medication for parkinsonian symptoms.

ANTIPSYCHOTIC AGENTS

Antipsychotics are divided into two major categories: *typical* (or *traditional*) and *atypical.* The **typical antipsychotics,** introduced in 1952, are subdivided into phenothiazines and nonphenothiazines. Nonphenothiazines include butyrophenones, dibenzoxazepines, dihydroindolones, and thioxanthenes. The phenothiazines and thioxanthenes block norepinephrine, causing sedative and hypotensive effects early in treatment. The butyrophenones block only the neurotransmitter dopamine.

Atypical antipsychotics make up the second category of antipsychotics. Clozapine, discovered in the 1960s and made available in Europe in 1971, was the first atypical antipsychotic agent. It was not marketed in the United States until 1990 because of adverse hematologic reactions. Atypical antipsychotics are effective for treating schizophrenia and other psychotic disorders in patients who do not respond to or are intolerant of typical antipsychotics. Because of their decreased side effects, atypical antipsychotics are often used instead of traditional typical antipsychotics as first-line therapy.

Pharmacophysiologic Mechanisms of Action

Antipsychotics block the actions of dopamine and thus may be classified as dopaminergic antagonists. There are five subtypes of dopamine receptors: D_1 through D_5. All antipsychotics block the D_2 (dopaminergic) receptor, which in turn promotes the presence of EPS, resulting in drug-induced pseudoparkinsonism in varying degrees. Atypical antipsychotics have a weak affinity to D_2 receptors, a stronger affinity to D_4 receptors, and they block the serotonin receptor. These agents cause fewer EPS than the typical (phenothiazines) antipsychotic agents, which have a strong affinity to D_2 receptors.

Adverse Reactions

Extrapyramidal Syndrome

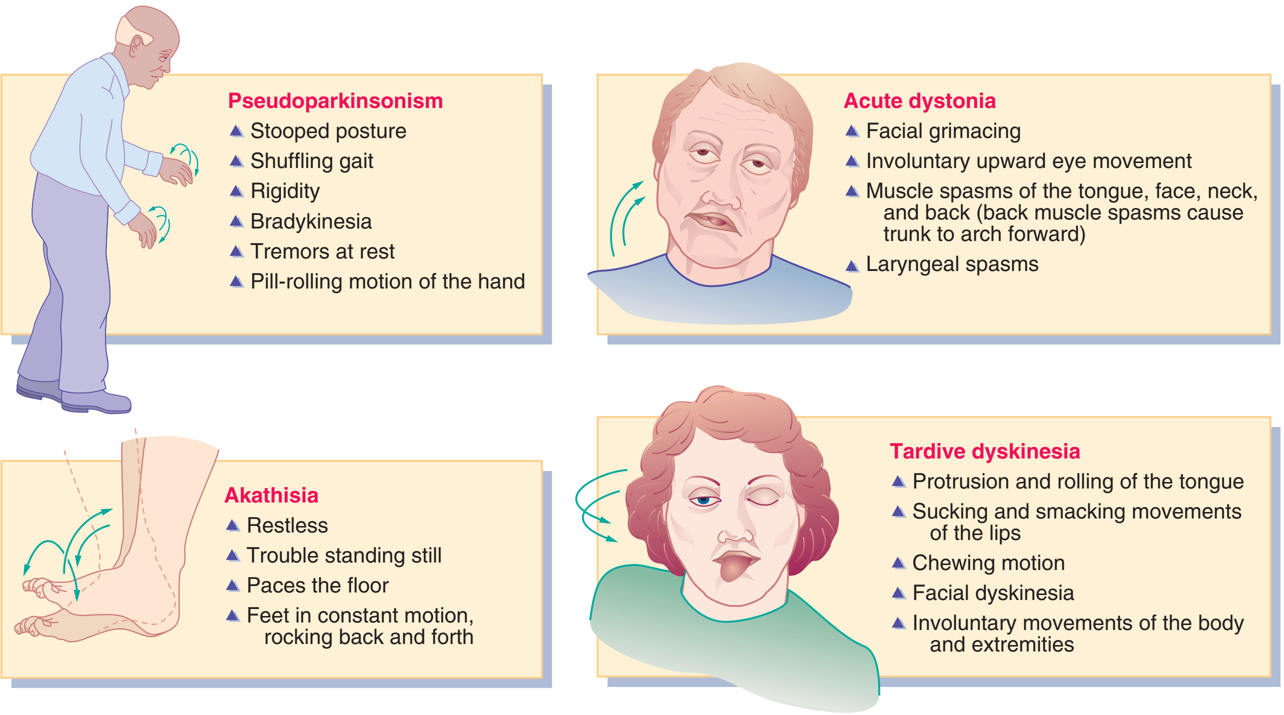
Pseudoparkinsonism, which resembles symptoms of Parkinson's disease, is a major side effect of typical antipsychotic drugs. Symptoms of pseudoparkinsonism, or EPS, include stooped posture, masklike facies, rigidity, tremors at rest, shuffling gait, pill-rolling motion of the hand, and bradykinesia. When patients take high-potency typical antipsychotic drugs, these symptoms are more pronounced. Patients who take low-strength antipsychotics such as chlorpromazine (Thorazine) are not as likely to have symptoms of pseudoparkinsonism as those who take fluphenazine (Prolixin).

During early treatment with typical antipsychotic agents for schizophrenia and other psychotic disorders, two adverse extrapyramidal reactions that may occur are acute dystonia and akathisia. Tardive dyskinesia is a later phase of extrapyramidal reaction to antipsychotics. Use of anticholinergic drugs helps decrease pseudoparkinsonism symptoms, acute dystonia, and akathisia, but has little effect on alleviating tardive dyskinesia.

HERBAL ALERT 27-1

Antipsychotic Agents

- Kava kava may increase the risk and severity of dystonic reactions when taken with phenothiazines.
- Kava kava may increase the risk and severity of dystonia when taken concurrently with fluphenazine.



Pseudoparkinsonism
▲ Stooped posture
▲ Shuffling gait
▲ Rigidity
▲ Bradykinesia
▲ Tremors at rest
▲ Pill-rolling motion of the hand
Acute dystonia
▲ Facial grimacing
▲ Involuntary upward eye movement
▲ Muscle spasms of the tongue, face, neck, and back (back muscle spasms cause trunk to arch forward)
▲ Laryngeal spasms
Akathisia
▲ Restless
▲ Trouble standing still
▲ Paces the floor
▲ Feet in constant motion, rocking back and forth
Tardive dyskinesia
▲ Protrusion and rolling of the tongue
▲ Sucking and smacking movements of the lips
▲ Chewing motion
▲ Facial dyskinesia
▲ Involuntary movements of the body and extremities

FIGURE 27–1 Characteristics of pseudoparkinsonism, acute dystonia, akathisia, and tardive dyskinesia.

The symptoms of **acute dystonia** usually occur in 5% of patients within days of taking typical antipsychotics. Characteristics of the reaction include muscle spasms of the face, tongue, neck, and back; facial grimacing; abnormal or involuntary upward eye movement; and laryngeal spasms that can impair respiration. This condition is treated with anticholinergic/antiparkinsonism drugs such as benztropine (Cogentin). The benzodiazepine lorazepam (Ativan) may also be prescribed.

Akathisia occurs in approximately 20% of patients who take a typical antipsychotic drug. With this reaction, the patient has trouble standing still, is restless, paces the floor, and is in constant motion (e.g., rocks back and forth). Akathisia is best treated with a benzodiazepine (e.g., lorazepam) or a beta blocker (e.g., propranolol).

Tardive dyskinesia is a serious adverse reaction occurring in approximately 20% to 30% of patients who have taken a typical antipsychotic drug for more than 1 year. The prevalence is higher in cigarette smokers. The likelihood of developing tardive dyskinesia depends on the dose and duration of the antipsychotic factor. Characteristics of tardive dyskinesia include protrusion and rolling of the tongue, sucking and smacking movements of the lips, chewing motion, and involuntary movement of the body and extremities. In older adults, these reactions are more frequent and severe. The antipsychotic drug should be stopped in all who experience tardive dyskinesia and another antipsychotic agent substituted. Benzodiazepines, calcium channel blockers, or beta blockers are helpful in some cases in decreasing tardive dyskinesia. No one agent is effective for all patients. High doses of vitamin E may be helpful, and its use to treat tardive dyskinesia is currently under investigation. Clozapine (Clozaril) has also been effective for treating tardive dyskinesia. Tetrabenazine (Xenazine), used to improve symptoms of Huntington's disease, seems to be effective in treating tardive dyskinesia. Tetrabenazine reduces dopamine, norepinephrine, and serotonin levels. Amantadine has also been helpful in reducing drug-induced involuntary movements. Figure 27-1 shows the characteristics of pseudoparkinsonism, acute dystonia, akathisia, and tardive dyskinesia.

Neuroleptic Malignant Syndrome

Neuroleptic malignant syndrome (NMS) is a rare but potentially fatal condition associated with antipsychotic drugs. Predisposing factors include excess agitation, exhaustion, and dehydration. NMS symptoms involve muscle rigidity, sudden high fever, altered mental status, blood pressure fluctuations, tachycardia, dysrhythmias, seizures, rhabdomyolysis, acute renal failure, respiratory failure, and coma. Treatment of NMS involves immediate withdrawal of antipsychotics, adequate hydration, hypothermic blankets, and administration of antipyretics, benzodiazepines, and muscle relaxants such as dantrolene (Dantrium).

Phenothiazines

Chlorpromazine hydrochloride (Thorazine) was the first phenothiazine introduced for treating psychotic behavior in patients in psychiatric hospitals. The **phenothiazines** are subdivided into three groups: aliphatic, piperazine, and piperidine, which differ mostly in their side effects.

TABLE 27-1 EFFECTS OF PHENOTHIAZINES (VARIES WITHIN CLASS)

GROUP	SEDATION	HYPOTENSION	EPS	ANTIEMETIC
aliphatic	+++	+++	++	++
chlorpromazine and triflupromazinec				+++
piperazine	++	+	+++	+++
piperidine	+++	+++	+	—
Nonphenothiazines				
haloperidol	+	+	+++	+++
loxapine	++	++	+++	—
molindone	+/++	+	+++	—
thiothixene	+	+	+++	—
Atypical Antipsychotics				
risperidone	+	+	+/0	—

—, No effect; +, mild effect; ++, moderate effect; +++, severe effect; *EPS*, extrapyramidal symptoms.

The *aliphatic phenothiazines* produce a strong sedative effect, decreased blood pressure, and may cause moderate EPS (pseudoparkinsonism). Chlorpromazine hydrochloride is in the aliphatic group and may produce pronounced **orthostatic hypotension** (low blood pressure that occurs when an individual assumes an upright position from a supine position).

The *piperazine phenothiazines* produce more EPS than other phenothiazines. They cause dry mouth, urinary retention, and agranulocytosis. Examples of piperazine phenothiazines are fluphenazine (Prolixin) and perphenazine (Trilafon).

The *piperidine phenothiazines* have a strong sedative effect, cause few EPS, have a low to moderate effect on blood pressure, and have no antiemetic effect. Thioridazine (Mellaril) is an example of piperidine phenothiazines. Table 27-1 summarizes the effects of the phenothiazines.

Most antipsychotics can be given orally (tablet or liquid), intramuscularly (IM), or intravenously (IV). For oral use, the liquid form might be preferred, because some patients hide tablets to avoid taking them. In addition, the absorption rate is faster with the liquid form. Peak serum drug level occurs in 2 to 3 hours. The antipsychotics are highly protein bound (>90%), and excretion of the drugs and their metabolites is slow. Phenothiazines are metabolized by liver enzymes into phenothiazine metabolites. Metabolites can be detected in the urine several months after the medication has been discontinued. Phenothiazine metabolites may cause a harmless pinkish to red-brown urine color. The *full* therapeutic effects of antipsychotics may not be evident for 3 to 6 weeks following initiation of therapy, but an observable therapeutic response may be apparent after 7 to 10 days.

Noncompliance with antipsychotics is common. Encourage the patient to take the medication as prescribed. Explain and emphasize essential information to compensate for patients' knowledge deficit, and provide an interpreter for patients whose first language is not English.

Prototype Drug Chart 27-1 shows the drug characteristics of fluphenazine (Prolixin), a phenothiazine antipsychotic used to manage psychosis. Box 27-1 shows the symptoms and suggested treatment for overdose of phenothiazines.

BOX 27-1 SYMPTOMS AND SUGGESTED TREATMENT FOR OVERDOSE OF PHENOTHIAZINES

Symptoms

- Unable to arouse; blood pressure fluctuations; tachycardia; agitation; delirium; convulsions; dysrhythmias; neuroleptic malignant syndrome; extrapyramidal symptoms; and renal, cardiac, and respiratory failure.

Treatment

- Maintain airway, gastric lavage, activated charcoal administration, adequate hydration, anticholinergics, and norepinephrine.

Pharmacokinetics Oral absorption of fluphenazine is rapid and not affected by food. This drug is strongly protein-bound and has a long half-life; therefore, the drug may accumulate. Fluphenazine is metabolized by the liver, crosses the blood-brain barrier and placenta, and is excreted as metabolites primarily in the urine. With hepatic dysfunction, the phenothiazine dose may need to be decreased. Lack of drug metabolism in the liver will cause an elevation in serum drug level.

Pharmacodynamics Fluphenazine is prescribed primarily for psychotic disorders. This drug has anticholinergic properties and should be cautiously administered to patients with glaucoma, especially narrow-angle glaucoma. Because hypotension is a side effect of these phenothiazines, any antihypertensives simultaneously administered can cause an additive hypotensive effect. Narcotics and sedative-hypnotics administered simultaneously with these phenothiazines can cause an additive CNS depression. Antacids decrease the absorption rate of both drugs and all phenothiazines, so they should be given 1 hour before or 2 hours after an oral phenothiazine.

The onset of action for fluphenazine hydrochloride is 1 hour, with a duration rate of 6 to 8 hours. Fluphenazine decanoate has delayed absorption, with an onset of action of 24 to 72 hours and a duration of 1 to 6 weeks.

Nonphenothiazines

The many groups of nonphenothiazine antipsychotics include butyrophenone, dibenzoxazepines, dihydroindolone, and thioxanthene.

PROTOTYPE DRUG CHART 27-1

Fluphenazine

Drug Class Antipsychotic: neuroleptic piperazine phenothiazine Trade Names: Prolixin, Decanoate Pregnancy Category: C	**Dosage** Psychoses: A: PO: 0.5-10 mg/d; *max:* 40 mg/d IM/subQ: HCl 2.5-10 mg/d; *max:* 100 mg/d Older adults: PO: 1-2.5 mg/d; *max:* 40 mg/d Decanoate: 12.5-25 mg q1-4wk
Contraindications Hypersensitivity, subcortical brain damage, blood dyscrasias, renal or liver damage, coma	**Drug-Lab-Food Interactions** Drug: Increase depressive effects when taken with alcohol or other CNS depressants Herbal: Kava kava may increase dystonia
Pharmacokinetics Absorption: Rapidly absorbed Distribution: PB 91%-99% Metabolism: t½: HCl—15 h; Decanoate—7-10 d Excretion: In urine	**Pharmacodynamics** PO: HCl: Onset: HCl—1 h; Decanoate—24-72 h Peak: HCl—0.5 h Duration: HCl—6-8 h; Decanoate—1-6 wk IM: Peak: HCl—1.5-2 h
Therapeutic Effects/Uses To manage symptoms of psychosis including schizophrenia Mode of Action: Blocks dopamine receptors in the brain and controls psychotic symptoms	
Side Effects Sedation, dizziness, headache, dry mouth, nasal congestion, blurred vision, photosensitivity, nausea, constipation, urinary retention, polyuria, peripheral edema	**Adverse Reactions** Hypertension, hypotension, tachycardia, extrapyramidal symptoms (tardive dyskinesia), impaired thermoregulation, convulsions Life-threatening: agranulocytosis

A, Adult; *CNS,* central nervous system; *d,* day; *h,* hour; *IM,* intramuscular; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *t ½,* half-life; *wk,* week.

In the *butyrophenone* group, a frequently prescribed nonphenothiazine is haloperidol (Haldol). Haloperidol's pharmacologic behavior is similar to that of the phenothiazines. It is a potent antipsychotic drug in which the equivalent prescribed dose is smaller than drugs of lower potency (e.g., chlorpromazine). The drug dose for haloperidol is 0.5 to 5 mg, whereas the drug dose for chlorpromazine is 10 to 25 mg. Long-acting preparations (haloperidol decanoate [Haldol] and fluphenazine decanoate [Prolixin]) are given for slow release via injection every 2 to 4 weeks. Administration precautions should be taken to prevent soreness and inflammation at the injection site. Because the medication is a viscous liquid, a large-gauge needle (e.g., 21-gauge) should be used with the Z-track method for administration in a deep muscle. See Chapter 4 for further explanation of the Z-track method of injection. The injection site should not be massaged, and sites should be rotated. These medications should not remain in a plastic syringe longer than 15 minutes. Prototype Drug Chart 27-2 provides the drug data related to haloperidol.

Pharmacokinetics Haloperidol is absorbed well through the gastrointestinal (GI) mucosa. It has a long half-life and is highly protein-bound, so the drug may accumulate. Haloperidol is metabolized in the liver and excreted in urine and feces.

Pharmacodynamics Haloperidol alters the effects of dopamine by blocking dopamine receptors; thus sedation and EPS may occur. The drug is used to control psychoses and decrease agitation in adults and children. Dosages need to be decreased in older adults because of decreased liver function and potential side effects. It may be prescribed for children with hyperactive behavior. Haloperidol has anticholinergic activity, so care should be taken when administering it to patients with a history of glaucoma.

Haloperidol has a similar onset of action, peak time of concentration, and duration of action as phenothiazines. It has strong EPS effects. Skin protection is necessary for prolonged use because of the possible side effect of photosensitivity.

From the *dibenzoxazepine* group, loxapine (Loxitane) is a moderately potent agent. It has moderate sedative and orthostatic hypotensive effects and a strong EPS effect.

The typical antipsychotic molindone hydrochloric acid (Moban) from the *dihydroindolone* group is a moderately potent agent. It has low sedative and orthostatic hypotensive effects and a strong EPS effect.

In the nonphenothiazine group known as *thioxanthenes* is thiothixene (Navane), a highly potent typical antipsychotic drug. It has side effects similar to those of molindone with low sedative and orthostatic hypotensive effects and a strong EPS effect.

Side Effects and Adverse Reactions

Several side effects are associated with antipsychotics. The most common side effect for all antipsychotics is drowsiness. Many of the antipsychotics have some anticholinergic effects: dry mouth, increased heart rate, urinary retention,

PROTOTYPE DRUG CHART 27-2

Haloperidol and Haloperidol Decanoate

Drug Class

Antipsychotic: neuroleptic (nonphenothiazine)
Trade Names: Haldol
Pregnancy Category: C

Dosage

A: PO: 0.2-0.5 mg q.d./b.i.d., increase to 4 mg/d PRN
IM: 2-10 mg; may repeat q1h PRN; Deconoate: 50-100 mg q4wk
C: PO: 0.05-0.15 mg/kg/d in divided doses; (not for child <3 y)
Older adults: Decreased doses PO: 0.25-2 mg b.i.d./t.i.d.; *max:* 4 mg/d

Contraindications

Narrow-angle glaucoma; severe hepatic, renal, and cardiovascular diseases; bone marrow depression; Parkinson's disease; blood dyscrasias; CNS depression; subcortical brain damage

Drug-Lab-Food Interactions

Drug: Increase sedation with alcohol, CNS depressants; increase toxicity with anticholinergics, CNS depressants, lithium; decrease effects with phenobarbital, carbamazepine; decrease effects with caffeine

Pharmacokinetics

Absorption: PO: 60% absorbed
Distribution: PB: 92%
Metabolism: t½: 24 h
Excretion: In urine and feces

Pharmacodynamics

PO: Onset: erratic
Peak: 2-6 h
Duration: 24-72 h
IM: Onset: 15-30 min
Peak: 30-45 min
Duration: 4-8 h
IM: Decanoate: Onset: UK
Peak: 6-7 d
Duration: 3-4 wk

Therapeutic Effects/Uses

To treat acute and chronic psychoses, to treat children with severe behavior problems who are combative, to suppress narcotic withdrawal symptoms, to treat schizophrenia resistant to other drugs, to treat Tourette syndrome, to treat symptoms of dementia in older adults
Mode of Action: Alters the effect of dopamine on CNS; mechanism for antipsychotic effects are unknown

Side Effects

Sedation, extrapyramidal symptoms, orthostatic hypotension, headache, photosensitivity, dry mouth and eyes, blurred vision

Adverse Reactions

Tachycardia, seizures, urinary retention
Life-threatening: Laryngospasm, respiratory depression, cardiac dysrhythmias, NMS, agranulocytosis

A, Adult; *b.i.d.,* twice a day; *C,* child; *CNS,* central nervous system; *d,* day; *h,* hour; *IM,* intramuscular; *min,* minute; *NMS,* neuroleptic malignant syndrome; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *t ½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week; *y,* year; *<,* less than.

and constipation. Blood pressure decreases with the use of antipsychotics; aliphatics and piperidines cause a greater decrease in blood pressure than the others.

EPS can begin within 5 to 30 days after initiation of antipsychotic therapy and are most prevalent with the phenothiazines, butyrophenones, and thioxanthenes. These symptoms include pseudoparkinsonism, akathisia, **dystonia** (prolonged muscle contractions with twisting, repetitive movements), and tardive dyskinesia. Tardive dyskinesia may develop in 20% of patients taking antipsychotics for long-term therapy. Antiparkinsonian anticholinergic drugs may be given to control EPS, but they are not always effective in treating tardive dyskinesia.

High dosing or long-term use of some antipsychotics can cause **blood dyscrasias** (blood cell disorders) such as agranulocytosis. White blood cell (WBC) count should be closely monitored and reported to the health care provider if there is an extreme decrease in leukocytes.

Dermatologic side effects seen early in drug therapy are pruritus and marked photosensitivity. Patients are urged to use sunscreen, hats, and protective clothing and to stay out of the sun.

Drug Interactions

Because phenothiazine lowers the seizure threshold, dosage adjustment of an anticonvulsant may be necessary. If either aliphatic phenothiazine or the thioxanthene group is administered, a higher dose of anticonvulsant might be necessary to prevent seizures.

Antipsychotics interact with alcohol, hypnotics, sedatives, narcotics, and benzodiazepines to potentiate the sedative effects of antipsychotics. Atropine counteracts EPS and potentiates antipsychotic effects. Use of antihypertensives can cause an additive hypotensive effect.

Antipsychotics should *not* be given with other antipsychotic or antidepressant drugs except to control psychotic behavior for selected individuals who are refractory to drug therapy. Under ordinary circumstances, if one antipsychotic drug is ineffective, a different one is prescribed. Individuals should *not* take alcohol or other CNS depressants (e.g., narcotic analgesics, barbiturates) with antipsychotics, because additive depression is likely to occur.

When discontinuing antipsychotics, the drug dosage should be reduced gradually to avoid sudden recurrence of psychotic symptoms. Table 27-2 lists common antipsychotic

TABLE 27-2 PHENOTHIAZINES AND NONPHENOTHIAZINES

GENERIC (BRAND)	DRUG POTENCY	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Phenothiazines			
Aliphatics			
chlorpromazine HCl (Thorazine)	Low	A: PO: 25-100 mg t.i.d./q.i.d. A: IM/IV: 25-50 mg q4-6h C >6 mo: PO: 0.55 mg/kg q4-6h C >6 mo: IM/IV: 0.5-1 mg/kg q6-8h	For psychosis, schizophrenia, intractable hiccups, preoperative sedation, behavioral problems in children, nausea, and vomiting. Pregnancy category: C; PB: 95%; t½: 24 h
Piperazines			
fluphenazine HCl (Prolixin)	High	See Prototype Drug Chart 27-1.	
perphenazine (Trilafon)	Moderate	A: PO: 4-16 mg b.i.d./t.i.d./q.i.d.; *max:* 64 mg/d	For psychotic disorders; to control severe nausea and vomiting; to treat intractable hiccups. Used also before chemotherapy to prevent nausea. Pregnancy category: C; PB: 91%-97%; t½: 9-12 h
Piperidines			
thioridazine HCl (Mellaril)*	Low	A: PO: 50-100 mg t.i.d.; *max:* 300 mg/d Older adults: 10 mg t.i.d.; *max:* 300 mg/d C 2-12 y: PO: 0.5-3 mg/kg/d in 2-3 divided doses; *max:* 3 mg/kg/d	For psychosis only when unresponsive to other medications. Higher doses for severe psychosis. Lower doses (10-50 mg t.i.d.) for marked depression, alcohol withdrawal, intractable pain. Few EPS. Little antiemetic effect. Can cause life-threatening dysrhythmias. Pregnancy category: C; PB: 91%-99%; t½: 24-34 h
Nonphenothiazines			
Butyrophenone			
haloperidol (Haldol)	High	See Prototype Drug Chart 27-2.	
Dibenzoxazepine			
loxapine (Loxitane)	Moderate	A: PO: Initially 10-25 mg q12h; maintenance 60-100 mg/d in divided doses; *max:* 250 mg/d Older adults: 5-10 mg daily/b.i.d.; maintenance 40-50 mg/d; *max:* 250 mg/d	For acute psychosis and schizophrenia. Likely to cause EPS. Overdose can cause cardiac toxicity or neurotoxicity. Pregnancy category: C; PB: 95%; t½: 8 h
Dihydroindolone			
molindone HCl (Moban)	Moderate	A: PO: Initial: 50-75 mg in 3-4 divided doses, then 15-50 mg t.i.d./q.i.d.; *max:* 225 mg/d Older adults: ⅓-½ adult dose	Management of schizophrenia. Can cause EPS. Has less sedative effect. Pregnancy category: C; PB: UK; t½: 1.5 h
Thioxanthenes			
thiothixene HCl (Navane)	High	A: PO: 2 mg t.i.d.; *max:* 60 mg/d	Management of psychotic disorders, especially acute and chronic schizophrenia. Can cause EPS. Pregnancy category: C; PB: 90%; t½: 34 h
Atypical Antipsychotics			
clozapine (Clozaril)	Low	A: PO: Initially: 12.5 mg/d or b.i.d.; if tolerated, gradually increase to 300-450 mg/d in 3 divided doses; *max:* 900 mg/d	For severely ill schizophrenic patients, especially those who do not respond to other antipsychotics. With long-term use, monitor white blood cell count. Pregnancy category: B; PB: 95%; t½: 8-12 h

TABLE 27-2 PHENOTHIAZINES AND NONPHENOTHIAZINES—cont'd

GENERIC (BRAND)	DRUG POTENCY	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
olanzapine (Zyprexa Zydis) Extended-release injectable (Zyprexa Relprevv)	UK	A: IM: 5-10 mg/d; *max:* 20 mg/d Older adults: PO: 5 mg q.d.; *max:* 20 mg/d A: IM: IR: 5-10 mg/d Older adults: IM: 2.5-5 mg/d A: IM: ER: 150-300 mg q2wk or 405 mg q4wk Older adults: IM: ER: 150 q4wk	Treatment of schizophrenia. Does not cause EPS. May cause headaches, dizziness, excess weight gain, agitation, insomnia, and somnolence. Pregnancy category: C; PB: 93%; t½: 21-54 h
quetiapine (Seroquel)	UK	A: PO: Initially 25 mg/b.i.d.; increase 25-50 mg b.i.d./t.i.d. first week up to 300-400 mg/d in 2-3 divided doses; *max:* 800 mg/d Older adults: PO: 25 mg b.i.d.; increase q.d.; *max:* 400 mg/d A: XR: 300 mg h.s.; *max:* 800 mg/d Older adults: XR: 50 mg/d, increase 50 mg/d; *max:* 200-800 mg/d	Treatment of schizophrenia, bipolar disorder, and major depression. Not likely to cause EPS. May cause dizziness, headache, sedation. Pregnancy category: C; PB: 83%; t½: 6 h
asenapine (Saphris)	UK	A: SL: 5-10 mg b.i.d.; *max:* 20 mg/d	For treatment of schizophrenia and manic bipolar disorder. Adverse effects include dizziness, appetite stimulation, dysrhythmias, and pseudoparkinsonism. Pregnancy category: C; PB: UK; t½: 24 h
risperidone (Risperdal)	Low	Psychosis: A: PO: Initially 2 mg/d, increase to 4-8 mg/d Older adults: PO: Initially 0.5-1.5 mg b.i.d.; *max:* 4 mg/d Adol: PO: Initially 0.5 mg q.d., increase up to 3 mg/d	For management of schizophrenia. May cause sedation, headaches, sexual dysfunction, hyperglycemia, EPS, and NMS. Pregnancy category: C; PB: 90%; t½: 24 h
ziprasidone (Geodon)	UK	A: PO: 20 mg b.i.d. may increase q2d; *max:* 160 mg/d A: IM: 10 mg q2h or 20 mg q4h; *max:* 40 mg/d	For management of schizophrenia. Pregnancy category: C; PB: 99%; t½: 7 h
iloperidone (Fanapt)	UK	A: PO: Initially 1 mg b.i.d., then 6-12 mg b.i.d.; *max:* 24 mg/d	For treatment of schizophrenia. Adverse effects include GI distress, blurred vision, confusion, dehydration, dysrhythmias, and pseudoparkinsonism. Pregnancy category: C; PB: 95%; t½: 18-33 h
aripiprazole (Abilify)	UK	See Prototype Drug Chart 27-3.	
paliperidone (Invega, Invega Sustenna)	UK	A: PO: 6-12 mg/d in the AM; *max:* 12 mg/d A: IM: ER: 39-234 mg/mo	Treatment of schizophrenia. Extended-release injectable is given once a month. Pregnancy category: C; PB: 74%; t½: 23 h

drugs (phenothiazines and nonphenothiazines) and their dosages, uses, and considerations.

Antipsychotic Dosage for Older Adults

Older adults usually require smaller doses of antipsychotics—from 25% to 50% less than young and middle-aged adults. Regular to high doses of antipsychotics increase the risk of severe side effects. Dosage amounts need to be individualized according to the patient's age and physical status. In addition, dosage changes may be necessary during antipsychotic therapy. Antipsychotics have a black box warning that states: Increased mortality in elderly patients with dementia-related psychosis.

Atypical (Serotonin/Dopamine Antagonists) Antipsychotics

Atypical antipsychotics differ from typical/traditional antipsychotics in that the atypical agents are effective in treating both positive and negative symptoms of schizophrenia. The typical antipsychotics have not been effective in the treatment of negative symptoms. Two advantages of the atypical agents are that (1) they are effective in treating negative symptoms, and (2) they are not likely to cause EPS, including tardive dyskinesia. Atypical drugs available include clozapine, risperidone, olanzapine, ziprasidone, and aripiprazol. These agents have a greater affinity for blocking serotonin and dopaminergic D_4 receptors than primarily blocking the dopaminergic D_2 receptor responsible for mild and severe EPS. Weight gain, drowsiness, unsteady gait, headache, insomnia, depression, diabetes mellitus, and dyslipidemia are common side effects of atypical antipsychotics.

Clozapine (Clozaril) was the first atypical antipsychotic agent used to treat schizophrenia and other psychoses. It is not as likely to cause EPS, although they may occur. Tremors and occasional rigidity have been reported. Serious adverse reactions of clozapine are seizures and agranulocytosis, a decrease in the production of granulocytes that involves the body's immune defenses. Currently clozapine is only indicated for the treatment of severely ill schizophrenic patients who have not responded to traditional antipsychotic drugs. The WBC count needs to be closely monitored for leukopenia; if the WBC (leukocyte) level falls below 3000 mm^3, clozapine should be discontinued. Seizures have been reported in 3% of patients taking the drug. Dizziness, sedation, tachycardia, orthostatic hypotension, and constipation are common side effects.

Another atypical agent used to treat positive and negative symptoms of schizophrenia is risperidone (Risperdal). Its action is similar to that of clozapine, and the occurrence of EPS and tardive dyskinesia is low. It does not cause agranulocytosis. Paliperidone (Invega) is the major active metabolite of risperidone and is an extended-release tablet with once-a-day dosing. Paliperidone should be swallowed whole and not chewed, divided, or crushed. The most common adverse effects include EPS, insomnia, headache, and akathisia.

The atypical antipsychotic olanzapine (Zyprexa), like clozapine and risperidone, is effective for treating positive and negative symptoms of schizophrenia. It does not cause agranulocytosis.

Quetiapine (Seroquel), like all the other atypical antipsychotics, is less likely to cause EPS. Tardive dyskinesia for long-term use has not been determined.

For individuals with cardiac dysrhythmias, ziprasidone (Geodon) must be prescribed with caution, because its use may lead to prolonged Q-T interval; ECGs should be monitored. Ziprasidone is contraindicated in patients with a history of prolonged Q-T interval or with other concurrent drugs known to prolong Q-T interval. Patients taking quetiapine, clozapine, risperidone, olanzapine, ziprasidone, and aripiprazole should be monitored for hyperglycemia and other symptoms of diabetes mellitus.

Prototype Drug Chart 27-3 illustrates drug characteristics of aripiprazole (Abilify), an atypical antipsychotic. When anxiety, hallucinations, agitation, mania, confusion, or depression and other symptoms are noted, the health care provider should check the medications that the patient is taking.

Nursing Process

Patient-Centered Collaborative Care

Phenothiazines and Nonphenothiazines

Assessment

- Assess baseline vital signs for use in future comparison.
- Obtain a health history from patient of present drug therapy. If patient is taking an anticonvulsant, drug dose might need to be increased, because antipsychotics tend to lower seizure threshold.
- Assess mental status, cardiac, eye, and respiratory disorders before start of drug therapy, and continue daily assessment.

Nursing Diagnoses

- Disturbed sleep pattern related to medication adverse effects
- Activity intolerance related to sedation
- Acute confusion related to psychosis
- Self-care deficit related to loss of motivation

Planning

- Patient's psychotic behavior will improve with medication(s) and psychotherapy.

Nursing Interventions

- Monitor vital signs. Orthostatic hypotension is likely to occur.
- Remain with patient while medication is taken and swallowed; some patients hide antipsychotics in the mouth to avoid taking them. ⚡
- Avoid skin contact with liquid concentrates to prevent contact dermatitis. Liquid must be protected from light and should be diluted with fruit juice. ⚡
- Administer oral doses with food or milk to decrease gastric irritation.
- Dilute oral solution of fluphenazine in fruit juice, water, or milk. Avoid apple juice and caffeinated drinks.
- Administer by IM route deep into muscle, because drug irritates fatty tissue. Do not administer intravenously.
- Check blood pressure for marked decrease or increase 30 minutes after drug is injected. ⚡
- Do *not* mix in same syringe with heparin, pentobarbital, cimetidine, or dimenhydrinate.
- Chill suppository in refrigerator for 30 minutes before removing foil wrapper.
- Observe for EPS: acute dystonia, akathisia, pseudoparkinsonism, and tardive dyskinesia (see Figure 27-1). Report these promptly to the health care provider.

PROTOTYPE DRUG CHART 27-3

Aripiprazole

Drug Class
Nonphenothiazine: atypical antipsychotic
Trade Name: Abilify
Pregnancy Category: C

Dosage
Psychosis:
A: PO: 10-15 mg/d, may increase q2wk; *max:* 30 mg/d
Adol: PO: 2 mg/d, may increase q2d; *max:* 30 mg/d

Contraindications
Hypersensitivity, dehydration, alcohol intoxication, hypovolemia, agranulocytosis, neutropenia, leucopenia, heart failure, suicidal ideation, myocardial infarction, diabetes mellitus, hyperglycemia, hypotension, seizures, parkinsonism

Drug-Lab-Food Interactions
Drug: Antidiabetic agents decrease Abilify drug levels and increase risk of hyperglycemia; alpha blockers and antihypertensives increase risk of hypotension; other antipsychotics enhance risk of NMS, EPS, tardive dyskinesia, anticholinergic effects, hypotension, and seizures; CNS depressants may increase sedation and orthostatic hypotension; SSRIs may increase risk of serotonin syndrome; calcium channel blockers may increase blood levels
Food: Grapefruit juice may increase blood levels
Herbal: St. John's wort may decrease blood levels
Lab: Increased blood glucose

Pharmacokinetics
Absorption: Well absorbed, not affected by food
Distribution: PB: 99%
Metabolism: t½: 75 h
Excretion: In urine and feces

Pharmacodynamics
PO: Onset: UK
Peak: 3-5 h
Duration: 24 h
IM: Onset: 1-3 h
Peak: UK
Duration: 24 h

Therapeutic Effects/Uses
To manage symptoms of psychosis, including schizophrenia
Mode of Action: Interferes with the binding of dopamine to dopamine (D_2) and serotonin 5-hydroxytryptamine (5-HT_2) receptors

Side Effects
Sedation, drowsiness, weight gain, weight loss, headaches, fatigue, blurred vision, photosensitivity, alopecia, peripheral edema, amenorrhea, hyperglycemia, hypoglycemia, insomnia, anxiety, agitation, dizziness, constipation, nausea, vomiting, arthralgia, dizziness, sexual dysfunction

Adverse Reactions
Orthostatic hypotension, hypertension, tachycardia, bradycardia, EPS, dysrhythmias, seizures, angina, angioedema, diabetes mellitus
Life-threatening: Suicidal ideation, NMS, agranulocytosis, neutropenia, leukopenia

A, Adult; *adol,* adolescent; *b.i.d.,* twice a day; *C,* child; *CNS,* central nervous system; *d,* day; *EPS,* extrapyramidal symptoms; *h,* hour; *IM,* intramuscular; *min,* minute; *NMS,* neuroleptic malignant syndrome; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *t ½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week; *y,* year; *<,* less than.

- Assess for symptoms of NMS: increased fever, pulse, and blood pressure; muscle rigidity; increased creatine phosphokinase and WBC count; altered mental status; acute renal failure; varying levels of consciousness; pallor; diaphoresis; tachycardia; and dysrhythmias.
- Record urine output as urinary retention may result.
- Monitor serum glucose level.

Patient Teaching

General

- Encourage patient to take the drug exactly as ordered. In schizophrenia and other psychotic disorders, antipsychotics do not cure the mental illness but do alleviate symptoms. Many patients on medication can function outside of the institution setting. Adherence to drug regimen is extremely important.
- Inform patient that medication may take 6 weeks or longer to achieve full clinical effect.
- Caution patient not to consume alcohol or other CNS depressants such as narcotics; these drugs intensify the depressant effect on the body.
- Recommend patient not to abruptly discontinue the drug. Seek advice from health care provider before making any changes in dosage.
- Encourage patient to read labels on OTC preparations. Some are contraindicated when taking antipsychotics.
- Teach smoking cessation, because smoking increases metabolism of some antipsychotics.
- Guide patient to maintain good oral hygiene by frequently brushing and flossing teeth.
- Encourage patient to talk with health care provider regarding family planning. The effect of antipsychotics on the fetus is not fully known; however, there may be teratogenic effects.

- Explain to the breastfeeding patient that phenothiazine passes into breast milk, possibly causing drowsiness and unusual muscle movement in the infant.
- Warn patient about importance of routine follow-up examinations.
- Encourage patient to obtain laboratory tests on schedule. WBCs are monitored for 3 months, especially during the start of drug therapy. Leukopenia, or decreased WBCs, may occur. Be alert to symptoms of malaise, fever, and sore throat, which may be an indication of agranulocytosis, a serious blood dyscrasia.
- Teach patient to report symptoms of infection promptly to the health care provider, especially when patient is taking clozapine.
- Advise patient to wear an identification bracelet indicating the medication taken.
- Inform patient that tolerance to sedative effect develops over a period of days or weeks.

Side Effects

- Direct patient to avoid potentially dangerous situations, such as driving, until drug dosing has been stabilized.
- Inform patient about EPS; instruct patient to promptly report symptoms to health care provider.
- Encourage patient to wear sunglasses for photosensitivity, to limit exposure to direct sunlight, and to use sunscreen and protective clothing to prevent a skin rash.
- Warn patient about orthostatic hypotension and possible dizziness.
- Teach patient who is taking aliphatic phenothiazines such as chlorpromazine that the urine might be pink or red-brown; this discoloration is harmless.
- Inform patient that changes may occur related to sexual functioning and menstruating. Women could have irregular menstrual periods or amenorrhea, and men might experience impotence and gynecomastia (enlargement of breast tissue).
- Suggest lozenges or hard candy if mouth dryness occurs. Advise patient to consult health care provider if dry mouth persists for more than 2 weeks.
- Encourage patient to avoid extremes in environmental temperatures and exercise.
- Advise patient to rise slowly from sitting or lying to standing to prevent a sudden decrease in blood pressure.

Cultural Considerations

- Recognize that some cultural groups may have difficulty in accepting the patient's disorder and need for medication.

Evaluation

- Evaluate the effectiveness of the drug and whether the patient has acceptably reduced psychotic symptoms at the *lowest* dose possible.
- Ascertain whether patient can cope with everyday living situations and attend to activities of daily living.
- Determine if any side effects of or adverse reactions to the drug have occurred.

SAFETY: Preventing Medication Errors

Do not confuse …

- **Seroquel** with **Serzone** (an antidepressant) or **sertindole** (Serlect)

ANXIOLYTICS

Anxiolytics, or *antianxiety drugs,* are primarily used to treat anxiety and insomnia. The major anxiolytic group is benzodiazepines (a minor tranquilizer group). Long before benzodiazepines were prescribed for anxiety and insomnia, barbiturates were used. Benzodiazepines are considered more effective than barbiturates, because they enhance the action of gamma-aminobutyric acid (GABA), an inhibitory neurotransmitter within the CNS. Benzodiazepines have fewer side effects and may be less dangerous in overdosing. Long-term use of barbiturates causes drug tolerance and dependence and may cause respiratory distress. Currently barbiturates are not drugs of choice for treating anxiety. Benzodiazepine-like drugs are used to treat insomnia. Selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors, tricyclic antidepressants, and monamine oxidase inhibitors are used to treat various anxiety disorders. These drugs are discussed in Chapter 28.

Table 27-3 lists approved uses for benzodiazepines. Drugs used to treat insomnia, including benzodiazepines, are discussed in Chapter 21.

A certain amount of anxiety may make one more alert and energetic, but when anxiety is excessive, it can be disabling, and anxiolytics may be prescribed. The action of anxiolytics resembles that of the sedative-hypnotics but *not* that of the antipsychotics.

There are two types of anxiety—primary and secondary. *Primary anxiety* is not caused by a medical condition or by drug use; *secondary anxiety* is related to selected drug use or medical or psychiatric disorders. Anxiolytics are not usually given for secondary anxiety unless the medical problem is untreatable, severe, and causes disability. In this case, an anxiolytic could be given for a short period to alleviate any acute anxiety attacks. These agents treat the symptoms but do not cure them. Long-term use of anxiolytics is discouraged, because tolerance develops within weeks or months, depending on the agent. Drug tolerance can occur in less than 2 to 3 months in patients who take phenobarbital.

Nonpharmacologic Measures

Some of the symptoms of a severe attack of anxiety, or panic attack, include dyspnea (difficulty in breathing), choking sensation, chest pain, heart palpitations, dizziness, faintness, sweating, trembling and shaking, and fear of losing control.

TABLE 27-3 APPROVED USES FOR BENZODIAZEPINES

PRESCRIBED USES	DRUGS
Anxiety	alprazolam (Xanax) chlordiazepoxide (Librium) clorazepate (Tranxene) diazepam (Valium) lorazepam (Ativan)
Anxiety associated with depression	alprazolam (Xanax) clonazepam (Klonopin) lorazepam (Ativan)
Insomnia: short-term use	estazolam (Prosom) flurazepam (Somnol) quazepam (Doral) temazepam (Restoril) triazolam (Halcion)
Seizures and status epilepticus	clonazepam (Klonopin) clorazepate (Tranxene) diazepam (Valium)—status epilepticus lorazepam (Ativan)—status epilepticus
Alcohol withdrawal	clorazepate (Tranxene) chlordiazepoxide (Librium) diazepam (Valium) lorazepam (Ativan)
Skeletal muscle spasms	diazepam (Valium)
Preoperative medications	chlordiazepoxide (Librium) diazepam (Valium) lorazepam (Ativan) midazolam (Versed)

Before giving anxiolytics, nonpharmacologic measures should be used for decreasing anxiety. These measures might include using a relaxation technique, psychotherapy, or support groups.

Benzodiazepines

Benzodiazepines have multiple uses as anticonvulsants, sedative-hypnotics, preoperative drugs, substance abuse withdrawal agents, and anxiolytics. Most of the benzodiazepines are used mainly for severe or prolonged anxiety. Examples include chlordiazepoxide (Librium), diazepam (Valium), clorazepate dipotassium (Tranxene), lorazepam (Ativan), and alprazolam (Xanax). The most frequently prescribed benzodiazepine is lorazepam. Many of the benzodiazepines are used for more than one purpose.

Benzodiazepines are lipid-soluble and are absorbed readily from the GI tract. They are highly protein-bound (80% to 98%). Benzodiazepines are primarily metabolized by the liver and excreted in urine, so the drug dosage for patients with liver or renal disease should be lowered accordingly to avoid possible cumulative effects. Traces of benzodiazepine metabolites could be present in the urine for weeks or months after the person has stopped taking the drug. These are controlled substance schedule IV (CSS IV) drugs.

The first benzodiazepine, chlordiazepoxide, became widely used for its sedative effect in 1962. Diazepam was the most frequently prescribed drug in the early 1970s. Lorazepam is the prototype drug of benzodiazepine and is described in Prototype Drug Chart 27-4.

HERBAL ALERT 27-2

Benzodiazepines

Kava kava should not be combined with benzodiazepines, because it increases the sedative effect.

Pharmacokinetics Lorazepam is highly lipid-soluble, and the drug is rapidly absorbed from the GI tract. The drug is highly protein-bound, and the half-life is 10 to 20 hours. Lorazepam is excreted primarily in the urine.

Pharmacodynamics Lorazepam acts on the limbic, thalamic, and hypothalamic levels of the CNS. The onset of action is 15 to 30 minutes by mouth and 1 to 5 minutes by IV. The serum levels of most oral doses of benzodiazepines peak in 2 hours. Oxazepam levels peak in 3 hours. Duration of action varies. The average is 2 to 3 hours when given orally; when given IV, the longest duration of action is 1 hour.

It is recommended that benzodiazepines be prescribed for no longer than 3 to 4 months. Beyond 4 months, the effectiveness of the drug lessens. Table 27-4 lists the anxiolytics and their dosages, uses, and considerations.

Miscellaneous Anxiolytics

The anxiolytic buspirone hydrochloride (BuSpar) binds to serotonin and dopamine receptors. It may not be effective until 1 to 2 weeks after continuous use. It has fewer side effects of sedation and physical and psychological dependency associated with many benzodiazepines. The most common side effects of buspirone include drowsiness, dizziness, headache, nausea, nervousness, and excitement. Note: Buspirone has an interaction with grapefruit juice that can lead to toxicity. To avoid this interaction, buspirone users should be advised to limit intake of grapefruit juice to 8 ounces daily or half of a grapefruit.

Nursing Process

Patient-Centered Collaborative Care

Benzodiazepines

Assessment

- Assess for suicidal ideation.
- Obtain a history of patient's anxiety reaction.
- Determine patient's support system (family, friends, groups), if any.
- Obtain patient's drug history. Report possible drug-drug interaction.

Nursing Diagnoses

- Anxiety related to situational crisis
- Impaired physical mobility related to drowsiness and weakness

PROTOTYPE DRUG CHART 27-4

Lorazepam

Drug Class
Anxiolytic: benzodiazepine
Trade Name: Ativan
Pregnancy Category: D

Dosage
Anxiety:
A: PO: 2-6 mg/d; *max:* 10 mg/d
Older adults: PO: 1-2 mg/d; *max:* 10 mg/d

Contraindications
Hypersensitivity, CNS depression, shock, coma, narrow-angle glaucoma, seizures, alcohol intoxication, liver impairment, pregnancy, lactation
Caution: Hepatic or renal dysfunction, suicidal ideation

Drug-Lab-Food Interactions
Drug: Increases CNS depression when taken with alcohol, CNS depressants, and anticonvulsants; cimetidine increases lorazepam plasma levels, increases phenytoin levels, decreases levodopa effects; smoking decreases antianxiety effects

Pharmacokinetics
Absorption: Rapid from GI tract
Distribution: PB: 91%
Metabolism: $t_{1/2}$: 12-14 h
Excretion: In urine

Pharmacodynamics
PO: Onset: UK
Peak: 2 h
Duration: 12-24 h
IM: Onset: 15-30 min
Peak: 60-90 min
Duration: UK
IV: Onset: 1-5 min
Peak: UK
Duration: UK

Therapeutic Effects/Uses
To control anxiety and to treat status epilepticus; for preoperative sedation; for substance withdrawal
Mode of Action: Potentiate gamma-aminobutyric (GABA) effects by binding to specific benzodiazepine receptors and inhibiting GABA neurotransmission

Side Effects
Drowsiness, dizziness, weakness, confusion, blurred vision, nausea, vomiting, anorexia, restlessness, hallucinations, anterograde amnesia, sleep-related behaviors

Adverse Reactions
Hypertension, hypotension, bradycardia, respiratory depression

A, Adult; *C,* child; *CNS,* central nervous system; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; $t_{1/2}$, half-life; *UK,* unknown.

Planning

- Patient's anxiety and stress will be reduced through nonpharmacologic methods, anxiolytic drugs, or support/group therapy.

Nursing Interventions

- Observe patient for side effects of anxiolytics. Recognize that drug tolerance and physical and psychological dependency can occur with most anxiolytics.
- Recognize that anxiolytic dosages should be lower for older adults, children, and debilitated persons than for middle-aged adults.
- Monitor vital signs, especially blood pressure and pulse; orthostatic hypotension may occur.
- Encourage family to be supportive of patient.

Patient Teaching

General

- Advise patient not to drive a motor vehicle or operate dangerous equipment when taking anxiolytics, because sedation is a common side effect.
- Warn patient not to consume alcohol or CNS depressants such as narcotics while taking an anxiolytic.
- Teach patient ways to control excess stress and anxiety (relaxation techniques, long walks).
- Inform patient that effective response may take 1 to 2 weeks.
- Encourage patient to follow drug regimen and not to abruptly stop taking the drug after prolonged use because withdrawal symptoms can occur. Drug dose is usually tapered when drug is discontinued.

Side Effects

- Encourage patient to rise slowly from sitting to standing position to avoid dizziness from orthostatic hypotension.

Cultural Considerations

- Use simple and clear instructions, modifying methods and materials to meet patient and family needs. Ask family members to assist with translation only if an

TABLE 27-4 **ANXIOLYTICS**

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Benzodiazepines		
alprazolam (Xanax) CSS IV	IR tablet, Orally disintegrating form: A: PO: 0.25-0.5 mg t.i.d.; *max:* 4 mg/d Older adults: 0.125-0.25 mg b.i.d.; *max:* 4 mg/d ER tablet: A: PO: 0.5-1 mg q.d. in morning Older adults: 0.5 mg/d; *max:* 10 mg/d	Management of anxiety and panic disorders and anxiety associated with depression. Side effects include drowsiness, dry mouth, and lightheadedness. Pregnancy category: D; PB: 90%; t½: 11-16 h
chlordiazepoxide HCl (Librium) CSS IV	Anxiety disorders: A: PO: 5-10 mg t.i.d./q.i.d. C: PO: 5 mg b.i.d./q.i.d. Acute alcohol withdrawal: A: PO: 50-100 mg q4h until agitation controlled; *max:* 300 mg/d	Effective for alcohol withdrawal syndrome (DTs), anxiety, and tension. Dose should be less for the older adult. Pregnancy category: D; PB: 96%; t½: 5-30 h
clorazepate dipotassium (Tranxene) CSS IV	A: PO: 15-60 mg/d in divided doses; *max:* 60 mg/d Older adults: 7.5-15 mg/d in divided doses; *max:* 60 mg/d	For anxiety, alcohol withdrawal syndrome, and partial seizures. Avoid taking alcohol or CNS depressants with clorazepate. Drowsiness and dizziness may occur. Pregnancy category: D; PB: 98%; t½: 40-50 h
diazepam (Valium) CSS IV	Anxiety, muscle spasm, and alcohol withdrawal: A: PO: 2-10 mg b.i.d./q.i.d. Older adults: PO: 2-2.5 mg q.d./b.i.d. C <6 mo: PO: 1-2.5 mg b.i.d./t.i.d. A: IM/IV: 2-5 mg; repeat in 3-4 h PRN Preoperative sedation: A: IV: 5-15 mg 15 min before procedure	Management of anxiety, muscle spasms, alcohol withdrawal, status epilepticus, and preoperative sedation. oxazepam (Serax) CSS IV	A: PO: 10-30 mg t.i.d./q.i.d; *max:* 120 mg/d Older adults: PO: 10 mg t.i.d.; *max:* 60 mg/d	For anxiety and acute alcohol withdrawal. Pregnancy category: D; PB: 85%-95%; t½: 5-15 h
Azapirones		
buspirone HCl (BuSpar)	A: PO: Initial: 7.5 mg b.i.d.; then 15-30 mg/d in divided doses; *max:* 60 mg/d Older adults: PO: 5 mg b.i.d.; then 15-30 mg/d in divided doses; *max:* 60 mg/d	For anxiety and anxiety-related depression. Takes several weeks before anxiolytic effects occur. Common side effects include drowsiness, dizziness, headache, and nausea. Pregnancy category: B; PB: 86%; t½: 2-4 h
Benzodiazepine Antagonists		
flumazenil (Romazicon)	A: IV: 0.2 mg over 15-30 sec; repeat 0.2 mg at 1-min intervals; *max:* 3 mg/h	Used to partially or completely reverse benzodiazepine dose from sedation, anesthesia, and overdose. Should not be used with antipsychotics or antidepressants. Pregnancy category: C; PB: 50%; t½: 40-80 min

A, Adult; *b.i.d.,* twice a day; *C,* child; *CNS,* central nervous system; *CSS,* Controlled Substances Schedule; *d,* day; *ER,* extended-release; *h,* hour; *IM,* intramuscular; *IR,* immediate-release; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown.

interpreter is not available, and do not ask private questions in public.

Evaluation

- Evaluate the effectiveness of drug therapy by determining if patient is less anxious and more able to cope with stresses and anxieties.
- Determine if patient is taking the anxiolytic drug as prescribed and adhering to patient teaching instructions.

Side Effects and Adverse Reactions

The side effects associated with benzodiazepines are sedation, dizziness, headaches, dry mouth, blurred vision, rare urinary incontinence, and constipation. Adverse reactions include leukopenia (decreased WBC count) with symptoms of fever, malaise, and sore throat; tolerance to the drug dosage with continuous use; and physical dependency. Box 27-2 lists guidelines for treating benzodiazepine overdose.

Benzodiazepines should not be abruptly discontinued, because withdrawal symptoms are likely to occur. Withdrawal

BOX 27-2 SUGGESTED TREATMENT FOR OVERDOSE OF BENZODIAZEPINES

1. Administer an emetic, and follow with activated charcoal if the patient is conscious; use gastric lavage if the patient is unconscious.
2. Administer the benzodiazepine antagonist flumazenil (Romazicon) IV if required.
3. Maintain an airway, give oxygen as needed for decreased respirations, and monitor vital signs.
4. Give IV vasopressors for severe hypotension.
5. Request a mental health consultation for the patient.

IV, intravenous.

symptoms caused by short-term benzodiazepine use are similar to those from the sedative-hypnotics (agitation, nervousness, insomnia, tremor, anorexia, muscular cramps, sweating). However, they are slow to develop, taking 2 to 10 days, and can last several weeks, depending on the benzodiazepine's half-life. When discontinuing a benzodiazepine, the drug dosage should be gradually decreased over a period of days, depending on dose or length of time on the drug. Withdrawal symptoms from long-term, high-dose benzodiazepine therapy include paranoia, delirium, panic, hypertension, and status epilepticus. Convulsions during withdrawal may be prevented with simultaneous substitution of an anticonvulsant. Alcohol and other CNS depressants should *not* be taken with benzodiazepines, because respiratory depression could result. Tobacco, caffeine, and sympathomimetics decrease the effectiveness of benzodiazepines. Benzodiazepines are contraindicated during pregnancy because of possible teratogenic effects.

KEY WEBSITES

Information on risperidone: *http://psyweb.com/drughtm/jsp/risper.jsp*

Information on lorazepam: *www.drugs.com/lorazepam.html*

CRITICAL THINKING CASE STUDY

FS, a 35-year-old woman, is receiving risperidone, 3 mg b.i.d., to control a psychotic disorder. She has taken the drug for 6 months but has recently become agitated and is complaining of insomnia.

1. What is the relation between FS's drug dose and her complaints? Explain your answer.
2. What further assessment should be made concerning FS and the drug regimen?
3. How does risperidone compare with other antipsychotics such as chlorpromazine, fluphenazine, olanzapine, and haloperidol regarding actions and adverse effects?

NCLEX STUDY QUESTIONS

1. The nurse suspects that a patient who is experiencing facial grimacing, involuntary upward eye movement, and muscle spasms of the tongue and face may have which condition?
   - a. Akathisia
   - b. Acute dystonia
   - c. Tardive dyskinesia
   - d. Pseudoparkinsonism
2. A patient asks the nurse to explain how antipsychotic drugs work to make him feel better. The nurse understands that antipsychotics act in which way?
   - a. Blocking actions of dopamine
   - b. Blocking actions of epinephrine
   - c. Promoting prostaglandin synthesis
   - d. Enhancing the action of gamma-aminobutyric acid
3. An antipsychotic agent, fluphenazine (Prolixin), is ordered for a patient with psychosis. The nurse understands that this agent can lead to extrapyramidal symptoms that may be treated with which medication?
   - a. quetiapine (Seroquel)
   - b. aripiprazole (Abilify)
   - c. benztropine (Cogentin)
   - d. chlorpromazine (Thorazine)
4. An atypical antipsychotic is prescribed for a patient with psychosis. The nurse understands that this category of medications includes which drugs? (Select all that apply.)
   - a. clozapine (Clozaril)
   - b. fluphenazine (Prolixin)
   - c. haloperidol (Haldol)
   - d. olanzapine (Zyprexa)
   - e. aripiprazole (Abilify)
5. A patient is prescribed lorazepam (Ativan). What does the nurse know to be true regarding lorazepam?
   - a. It may cause anterograde amnesia and sleep-related behaviors.
   - b. It has a maximum adult dose of 25 mg/day.
   - c. When combined with cimetidine, it causes plasma levels to be decreased.
   - d. It interferes with the binding of dopamine receptors.

6. A patient is receiving aripiprazole (Abilify). Which nursing intervention(s) will the nurse include in the patient's care plan? (Select all that apply.)
   - **a.** Administer before meals on an empty stomach to facilitate absorption.
   - **b.** Remain with the patient until medication is swallowed.
   - **c.** Monitor vital signs to detect orthostatic hypotension.
   - **d.** Assess the patient for evidence of neuroleptic malignant syndrome.
   - **e.** Observe the patient for acute dystonia, akathisia, and tardive dyskinesia.
7. A patient appears to have had an overdose of phenothiazines. The nurse anticipates that which intervention(s) may be used to treat phenothiazine overdose? (Select all that apply.)
   - **a.** Gastric lavage
   - **b.** Adequate hydration
   - **c.** Maintaining an airway
   - **d.** Fluphenazine (Prolixin)
   - **e.** Risperidone (Risperdal)
   - **f.** Activated charcoal administration

- Unfolding Case Studies

OBJECTIVES

- Contrast the various categories of different antidepressants, giving an example of one drug for each category.
- Describe the side effects and adverse reactions of antidepressants.
- Plan nursing interventions, including patient teaching, for antidepressants (tricyclic antidepressants, monoamine oxidase inhibitors, selective serotonin reuptake inhibitors, selective norepinephrine reuptake inhibitors, and atypical antidepressants).
- Explain the uses of lithium and its serum/plasma therapeutic ranges, side effects and adverse reactions, and nursing interventions.
- Apply the nursing process to the patient taking lithium, carbamazepine, and valproic acid.

KEY TERMS

antidepressants, p. 386
atypical antidepressants, p. 387
bipolar affective disorder, p. 387
depression, p. 386
dysphoria, p. 387
monoamine oxidase inhibitors, p. 387
reactive depression, p. 387
selective serotonin reuptake inhibitors, p. 387
serotonin norepinephrine reuptake inhibitors, p. 387
tricyclic antidepressants, p. 387

Antidepressants are used for depressive episodes that are accompanied by feelings of hopelessness and helplessness. They can be prescribed for 1 month to 12 months or perhaps longer.

Mood-stabilizer agents such as lithium are effective for bipolar affective disorder. Drug therapy for treating bipolar disorder is discussed in this chapter.

DEPRESSION

Depression is the most common psychiatric problem, affecting approximately 10% to 20% of the population. Only 33% of depressed persons receive medical or psychiatric help. Women between the ages of 25 and 45 years are two to three times more likely to experience major depression than men. Depression is characterized primarily by mood changes and loss of interest in normal activities. It is second only to hypertension as the most common chronic clinical condition.

Contributing causes of depression include genetic predisposition, social and environmental factors, and biologic conditions. Some signs of major depression include loss of interest in most activities, depressed mood, weight loss or gain, insomnia or hypersomnia, loss of energy, fatigue, feelings of despair, decreased ability to think or concentrate, and suicidal thoughts. Approximately 66% of all suicides are related to depression. Depressed men, especially older white men, are more likely to commit suicide successfully than depressed women. Antidepressants can mask suicidal tendencies.

The three types of depression are (1) *reactive,* (2) *major,* and (3) *bipolar affective disorder* (previously referred to as *manic depression*). **Reactive depression** usually has a sudden onset after a precipitating event (e.g., depression resulting from a loss, such as death of a loved one). The patient knows why he or she is depressed and may call this "the blues." Usually this type of depression lasts for months. A benzodiazepine agent may be prescribed. *Major depression* is characterized by loss of interest in work and home, inability to complete tasks, and deep depression **(dysphoria).** Major depression can be either primary (i.e., not related to other health problems) or secondary to a health problem (e.g., physical or psychiatric disorder or drug use). Antidepressants have been effective in treating major depression. **Bipolar affective disorder** involves swings between two moods, the manic (euphoric) and the depressive (dysphoria). Lithium (Lithobid) was originally the drug of choice for treating this type of disorder. Other mood stabilizers, such as carbamazepine (Tegretol), valproic acid or divalproex (Depakote, Valproate), and lamotrigine (Lamictal) are also currently first-line drugs of choice for bipolar disorder.

Pathophysiology

There are many theories about the cause of major depression. A common one suggests an insufficient amount of brain monoamine neurotransmitters (norepinephrine, serotonin, perhaps dopamine). It is thought that decreased levels of serotonin permit depression to occur, and decreased levels of norepinephrine cause depression. However, there can be other physiologic causes of depression as well as social and environmental factors.

Herbal Supplements for Depression

St. John's wort and gingko biloba have been suggested for the management of mild depression. St. John's wort can decrease reuptake of the neurotransmitters serotonin, norepinephrine, and dopamine. The use of these and many herbal products should be discontinued 1 to 2 weeks before surgery. The patient should check with the health care provider regarding herbal treatments (Herbal Alert 28-1).

HERBAL ALERT 28-1

Selective Serotonin Reuptake Inhibitors

- Feverfew may interfere with SSRI antidepressants such as fluoxetine (Prozac).
- St. John's wort interacts with SSRIs, which may cause serotonin syndrome (dizziness, headache, sweating, and agitation).

ANTIDEPRESSANT AGENTS

Antidepressants are divided into five groups: (1) **tricyclic antidepressants** (TCAs), or tricyclics; (2) **selective serotonin reuptake inhibitors** (SSRIs); (3) **serotonin norepinephrine reuptake inhibitors** (SNRIs); (4) **atypical antidepressants** that affect various neurotransmitters; and (5) **monoamine oxidase inhibitors** (MAOIs). TCAs and MAOIs were marketed in the late 1950s, and many of the SSRIs and atypical antidepressants were available in the 1980s. The SSRIs and SNRIs are popular antidepressants because they do not cause sedation, hypotension, anticholinergic effects, or cardiotoxicity as do many of the TCAs. Users of SSRIs can experience sexual dysfunction, which can be managed. With unpleasant side effects or lack of improvement, the patient is usually changed to another category.

Tricyclic Antidepressants

TCAs are used to treat major depression because they are effective and less expensive than SSRIs and other drugs. Imipramine was the first TCA marketed in the 1950s.

The action of TCAs is to block the uptake of the neurotransmitters norepinephrine and serotonin in the brain. The clinical response of TCAs occurs after 2 to 4 weeks of drug therapy. If there is no improvement after 2 to 4 weeks, the antidepressant is slowly withdrawn and another antidepressant is prescribed. *Polydrug therapy,* the practice of giving several antidepressants or antipsychotics together, should be avoided if possible because of potential serious side effects.

The effectiveness of TCAs in treating major depression is well documented. This group of drugs elevates mood, increases interest in daily living and activity, and decreases insomnia. For agitated depressed persons, amitriptyline (Elavil), doxepin (Silenor), or trimipramine (Surmontil) may be prescribed, because of their highly sedative effect. Frequently TCAs are given at night to minimize problems caused by their sedative action. When discontinuing TCAs, the drugs should be gradually decreased to avoid withdrawal symptoms such as nausea, vomiting, anxiety, and akathisia. Imipramine hydrochloride (Tofranil) is used for the treatment of enuresis (involuntary discharge of urine during sleep in children).

The TCA drugs include amitriptyline, imipramine, trimipramine, doxepin, desipramine, nortriptyline, and protriptyline. The TCA drugs desipramine and nortriptyline are major metabolites of imipramine and amitriptyline.

Pharmacokinetics Amitriptyline is strongly protein-bound. The half-life is 10 to 50 hours, and a cumulative drug effect may result. Amitriptyline is primarily excreted in urine.

Pharmacodynamics Amitriptyline is well absorbed, but antidepressant effects develop slowly over several weeks. The onset of the antidepressant effect of amitriptyline is 1 to 4 weeks, and the peak concentration is 2 to 12 hours. Drug doses are decreased for older patients to reduce side effects.

Side Effects and Adverse Reactions

The TCAs have many side effects: orthostatic hypotension, sedation, anticholinergic effects, cardiotoxicity, and seizures. Rising from a sitting position too rapidly can cause dizziness and lightheadedness, so the patient should be instructed to rise slowly to an upright position to avoid *orthostatic hypotension.* This group of antidepressants blocks the histamine receptors; thus, sedation is likely to occur initially but decreases with continuous use of the drug. Because TCAs block the cholinergic receptors, they can cause anticholinergic effects such as tachycardia, urinary retention, constipation, dry mouth, and blurred vision. Other side effects of TCAs include allergic reactions (skin rash, pruritus, and petechiae) and sexual dysfunction (impotence and amenorrhea). Most TCAs can cause blood dyscrasias (leukopenia, thrombocytopenia, and agranulocytosis) requiring close monitoring of blood cell counts. Amitriptyline may lead to extrapyramidal symptoms (EPS). Clomipramine may cause neuroleptic malignant syndrome (NMS). Seizure threshold is decreased by TCAs; therefore, patients with seizure disorders may need to have the TCA dose adjusted. The most serious adverse reaction to TCAs is cardiotoxicity, such as dysrhythmias that may result from high doses of the drug. The therapeutic serum range is 100 to 200 ng/mL.

Drug Interactions

Alcohol, hypnotics, sedatives, and barbiturates potentiate central nervous system (CNS) depression when taken with TCAs. Concurrent use of MAOIs with amitriptyline may lead to cardiovascular instability and toxic psychosis. Antithyroid medications taken with amitriptyline may increase the risk of dysrhythmias.

Selective Serotonin Reuptake Inhibitors

SSRIs block the reuptake of serotonin into the nerve terminal of the CNS, thereby enhancing its transmission at the serotonergic synapse. These drugs do not block the uptake of dopamine or norepinephrine, and they do not block cholinergic and alpha$_1$-adrenergic receptors. SSRIs are more commonly used to treat depression than are TCAs. They have fewer side effects than TCAs.

The primary use of SSRIs is for major depressive disorders. They are also effective for treating anxiety disorders such as obsessive-compulsive disorder, panic, phobias, posttraumatic stress disorder, and other forms of anxiety. Fluvoxamine (Luvox) is useful for treating obsessive-compulsive disorder in children and adults. SSRIs have also been used to treat eating disorders and selected drug abuses. Miscellaneous uses for SSRIs include decreasing premenstrual tension syndrome, preventing migraine headaches, and preventing or minimizing aggressive behavior in patients with borderline personality disorder.

The SSRIs include fluoxetine (Prozac), fluvoxamine (Luvox), sertraline (Zoloft), paroxetine (Paxil), citalopram (Celexa), and escitalopram (Lexapro). Fluoxetine (Prozac) has been effective in 50% to 60% of patients who fail to respond to TCA therapy (TCA-refractory depression). Of all of the SSRIs, sertraline (Zoloft) is the most commonly prescribed antidepressant. The U.S. Food and Drug Administration (FDA) approved a weekly fluoxetine dose of 90 mg. However, before taking the weekly dose, the patient should respond to a daily maintenance dose of 20 mg/d without serious effects. It has been reported that there are some side effects to the weekly 90 mg fluoxetine dose.

Note: Many SSRIs have an interaction with grapefruit juice that can lead to possible toxicity. It is recommended that daily intake be limited to 8 ounces of grapefruit juice or one half of a grapefruit.

Prototype Drug Chart 28-1 describes the drug characteristics of the SSRI fluoxetine (Prozac). Table 28-1 lists the side effects of the various antidepressants.

Pharmacokinetics Fluoxetine is strongly protein-bound. The half-life is 2 to 3 days; therefore a cumulative drug effect may result from long-term use. Fluoxetine is metabolized and excreted by the kidneys.

Pharmacodynamics Fluoxetine is well absorbed; however, its antidepressant effect develops slowly over several weeks. The onset of fluoxetine's antidepressant effect is between 1 and 4 weeks, and peak concentration is at 6 to 8 hours after ingestion. The drug dose for older adults should be decreased to reduce side effects.

Side Effects and Adverse Reactions

Fluoxetine produces common side effects such as dry mouth, blurred vision, insomnia, headache, nervousness, anorexia, nausea, diarrhea, and suicidal ideation. Fluoxetine has fewer side effects than amitriptyline (see Table 28-1).

Some patients may experience sexual dysfunction when taking SSRIs. Men have discontinued taking fluoxetine (Prozac) after experiencing a decrease in sexual arousal. Some women have become anorgasmic when taking paroxetine HCl (Paxil). The side effects often decrease or cease over the 2- to 4-week period of waiting for the therapeutic effect to emerge.

Serotonin Norepinephrine Reuptake Inhibitors

Venlafaxine (Effexor) was the first SNRI approved for major depression in 1993. SNRIs inhibit the reuptake of serotonin and norepinephrine, increasing availability in the synapse. SNRIs are used for major depression. Other approved uses are for generalized anxiety disorder and social anxiety disorder. Other SNRIs include duloxetine (Cymbalta) and desvenlafaxine (Pristiq). The concurrent interaction of venlafaxine and St. John's wort may increase the risk of serotonin syndrome and neuroleptic malignant syndrome. Prototype Drug Chart 28-2 describes the drug characteristics of venlafaxine.

Pharmacokinetics Venlafaxine is well absorbed. The protein binding capacity of venlafaxine is 27%, and the half-life is 5 hours. It is mostly excreted in the urine.

PROTOTYPE DRUG CHART 28-1

Fluoxetine

Drug Class Antidepressant: selective serotonin reuptake inhibitor Trade Name: Prozac Pregnancy Category: C	**Dosage** A: PO: Initially 20 mg/d in AM; *max:* 80 mg/d C >7 y: PO: Initially 10 mg/d; *max:* 40 mg/d Therapeutic range: 90-300 ng/mL
Contraindications Hypersensitivity, acute myocardial infarction, taking MAOIs, dehydration, breastfeeding Caution: Severe depression with suicidal tendency, severe liver or kidney disease, glaucoma, seizure disorder, diabetes mellitus, underweight adult	**Drug-Lab-Food Interactions** Drug: Increase effects of CNS and respiratory depression, and hypotensive effect with alcohol and CNS depressants Herb: St. John's wort increases risk for serotonin syndrome Increase effect of hypoglycemics
Pharmacokinetics Absorption: PO: well absorbed Distribution: PB: 95% Metabolism: fluoxetine: t½: 4-6 d Excretion: Excreted primarily in urine	**Pharmacodynamics** PO: Onset: 2-4 wk Peak: 6-8 wk Duration: UK
Therapeutic Effects/Uses To treat depression with or without melancholia; bulimia disorder; obsessive-compulsive disorder; panic disorder; and premenstrual dysphoric disorder Mode of Action: Serotonin is increased in nerve cells because of blockage from nerve fibers.	
Side Effects Headache, nervousness, restlessness, insomnia, blurred vision, mydriasis, tremors, dry mouth, anorexia, nausea, diarrhea, weight loss, menstrual irregularities, sexual dysfunction	**Adverse Reactions** Seizures, hyponatremia, dehydration, bleeding, osteopenia, suicidal ideation

A, Adult; *CNS,* central nervous system; *d,* day; *ECG,* electrocardiogram; *GI,* gastrointestinal; *MAOI,* monoamine oxidase inhibitor; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *wk,* week.

Pharmacodynamics The onset and duration of venlafaxine are unknown. The peak action is 2 to 4 hours for immediate-release tablets and 5.5 to 9 hours for extended-release tablets.

Side Effects and Adverse Effects

Side effects for venlafaxine include drowsiness, dizziness, insomnia, headache, euphoria, amnesia, blurred vision, photosensitivity, and ejaculation dysfunction. Adverse effects of this drug are hyponatremia, bleeding, hypertension, angioedema, blood dyscrasias, suicidal ideation, and Stevens-Johnson syndrome.

Atypical Antidepressants

Atypical antidepressants, or *second-generation antidepressants*, became available in the 1980s and have been used for major depression, reactive depression, and anxiety. They affect one or two of the three neurotransmitters: serotonin, norepinephrine, and dopamine. One of the first atypical antidepressants marketed was amoxapine (Asendin); others are maprotiline, nefazodone, and trazodone.

Amoxapine and maprotiline are sometimes considered to be TCAs because of their pharmacologic similarities. Atypical antidepressants should not be taken with MAOIs and should not be used within 14 days after discontinuing MAOIs. Trazodone may have a potential drug interaction with ketoconazole, ritonavir, and indinavir that may lead to increased trazodone levels and adverse effects. Table 28-2 lists the antidepressants and how each affects the various neurotransmitters.

Monoamine Oxidase Inhibitors

Another group of antidepressants is the MAOIs. The enzyme monoamine oxidase (MAO) inactivates norepinephrine, dopamine, epinephrine, and serotonin. By inhibiting MAO, the levels of these neurotransmitters rise. In the body, there are two forms of MAO enzyme: MAO-A and MAO-B. These enzymes are found primarily in the liver and brain. MAO-A inactivates dopamine in the brain, whereas MAO-B inactivates norepinephrine and serotonin. The MAOIs are nonselective, inhibiting both MAO-A and MAO-B. Inhibition of MAO by MAOIs is thought to relieve the symptoms of depression. Four MAOIs are currently prescribed: tranylcypromine sulfate (Parnate), isocarboxazid (Marplan), selegiline HCl (Emsam, Eldepryl), and phenelzine sulfate (Nardil). These MAOIs are detailed in Table 28-2.

For the treatment of depression, MAOIs are as effective as TCAs, but because of adverse reactions such as the risk of hypertensive crisis resulting from food and drug interactions, only 1% of patients taking antidepressants take an MAOI. Currently, MAOIs are not the antidepressants of choice and are usually prescribed when the patient does not respond to TCAs or second-generation antidepressants. However, MAOIs

PROTOTYPE DRUG CHART 28-2

Venlafaxine

Drug Class

Antidepressant: serotonin and norepinephrine reuptake inhibitor
Trade name: Effexor
Pregnancy Category: C

Dosage

Immediate-release:
A: PO: 75 mg/d in 2-3 divided doses; *max:* 225 mg/d in 3 divided doses
Extended-release:
A: PO: Initially 75 mg once daily or 37.5 once daily for 4-7 days to allow patient to adjust, then increase to 75 mg/d; *max:* 225 mg/d
Therapeutic serum range: 100-200 ng/mL

Contraindications

Hypersensitivity, taking MAOIs, CNS depression, SIADH, anticoagulant therapy, pregnancy, breastfeeding, children
Caution: Suicidal tendency, kidney dysfunction, narrow-angle glaucoma, seizures, underweight, hypovolemia, hyperthyroidism, recent MI, heart failure

Drug-Lab-Food Interactions

Drug: Increase effects of CNS, respiratory depression, and hypotensive effect with alcohol and CNS depressants
Hypertensive crisis and death may occur with MAOIs.
Increase drug levels and toxicity with cimetidine, haloperidol
Increase bleeding with anticoagulants, aspirin
Increase risk of serotonin syndrome and neuroleptic malignant syndrome with other SNRIs, SSRIs, serotonin receptor agonists (triptans), and amphetamines
Herb: St. John's wort may cause serotonin syndrome (potentially life-threatening state with tachycardia, hypertension, confusion, twitching, hyperreflexia, hyperthermia)

Pharmacokinetics

Absorption: PO: Well absorbed
Distribution: PB: 27%
Metabolism: t½: 5 h
Excretion: Excreted primarily in urine

Pharmacodynamics

Immediate-release:
PO: Onset: UK
Peak: 2-4 h
Duration: UK
Extended-release:
PO: UK
Peak: 5.5-9 h
Duration: UK

Therapeutic Effects/Uses

To treat depression with or without melancholia; generalized anxiety disorder; social anxiety disorder; panic disorder; and posttraumatic stress disorder
Mode of Action: Serotonin and norepinephrine are increased in nerve cells because of blockage from nerve fibers.

Side Effects

Drowsiness, dizziness, nervousness, insomnia, headache, euphoria, confusion, amnesia, blurred vision, cataracts, mydriasis, dry mouth and eyes, gingivitis, hirsutism, alopecia, sweating, photosensitivity, urinary retention, constipation, diarrhea, weight loss, nausea, anorexia, increased intraocular pressure, ejaculation dysfunction

Adverse Reactions

Bradycardia, tachycardia, hyponatremia, bleeding, hypertension, serotonin syndrome, neuroleptic malignant syndrome, angioedema
Life-threatening: Agranulocytosis, thrombocytopenia, leukopenia, seizures, suicidal ideation, myocardial infarction, heart failure, Stevens-Johnson syndrome

A, Adult; *b.i.d.,* twice a day; *C,* child; *CNS,* central nervous system; *d,* day; *ECG,* electrocardiogram; *h,* hour; *IM,* intramuscular; *MAOI,* monoamine oxidase inhibitor; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; SIADH, syndrome of inappropriate antidiuretic hormone secretion; *t ½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week; *>,* greater than.

are still used for mild, reactive, and atypical depression (chronic anxiety, hypersomnia, fear). MAOIs and TCAs should not be taken together when treating depression.

Drug and Food Interactions

Certain drug and food interactions with MAOIs can be fatal. Any drugs that are CNS stimulants or sympathomimetics (e.g., vasoconstrictors and cold medications containing phenylephrine and pseudoephedrine) can cause a hypertensive crisis when taken with an MAOI. In addition, foods that contain tyramine (cheese [cheddar, Swiss, bleu], cream, yogurt, coffee, chocolate, bananas, raisins, Italian green beans, liver, pickled foods, sausage, soy sauce, yeast, beer, and red wines) have sympathomimetic-like effects and can cause a hypertensive crisis. MAOI users *must avoid* these types of food and drugs. Frequent blood pressure monitoring is essential, and patient teaching regarding foods and over-the-counter (OTC) drugs to avoid is an important nursing responsibility. Because of the danger associated with hypertensive crisis, many psychiatrists will not prescribe MAOIs for depression unless other drugs have failed to be effective for the patient. However, this group of drugs is effective for treating depression if properly taken.

TABLE 28-2 ANTIDEPRESSANTS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Tricyclic Antidepressants		
amitriptyline HCl (Elavil, Tryptanol)	A: PO: 25-75 mg/d; *max:* 300 mg/d for inpatients, 200 mg/d for outpatients Older adults: PO: 10-25 mg h.s.; *max:* 150 mg/d Therapeutic serum range: 100-200 ng/mL	For depression with or without melancholia. Common side effects include drowsiness, dizziness, orthostatic hypotension, dry mouth, constipation, and urinary retention. Pregnancy category: C; PB: 95%; t½: 10-50 h
clomipramine HCl (Anafranil)	A: PO: 25-100 mg/d; *max:* 250 mg/d; after titration, entire dose may be given at bedtime C >10 y: PO: initially 25 mg/d, then 3 mg/kg/d; *max:* 200 mg/d	For depression and obsessive-compulsive disorder. Given at bedtime to reduce daytime sedation. Common side effects include tremor, dizziness, weight gain, and dry mouth. Pregnancy category: C; PB: 97%; t½: 20-30 h
desipramine HCl (Norpramin)	A: PO: Initially 50-75 mg/d; increase to 200 mg/d for outpatients; *max:* 300 mg/d for inpatients Adol/Older adults: Initially 25 mg/d h.s.; increase to 100 mg/d in divided doses; *max:* 150 mg/d Therapeutic serum range: 150-250 ng/mL	For depression. Has been used for attention deficit/hyperactivity disorder (ADHD). Take with food if GI distress occurs. Common side effects include drowsiness, dry mouth, urinary retention, and postural hypotension. Pregnancy category: C; PB: 90%; t½: 12-60 h
doxepin HCl (Sinequan)	A: PO: Initially 75 mg/d h.s. or in 2-3 divided doses; *max:* 300 mg/d Older adults/PO: Initially 10-25 mg/d; *max:* 300 mg/d C >12 y: PO: Initially 25-50 mg/d; *max:* 100 mg/d Therapeutic serum range: 30-50 ng/mL	For depression and anxiety related to involutional depression or bipolar disorder. Has less effect on cardiac status than other drugs in this group. Pregnancy category: C; PB: 80%-85%; t½: 6-8 h
imipramine HCl (Tofranil)	A: PO: 75-200 mg/d; *max:* 200 mg/d for outpatients, 300 mg/d for inpatients Older adults: 25-100 mg/d; *max:* 200 mg/d for outpatients, 300 mg/d for inpatients Therapeutic serum range: 150-250 ng/mL	For depression. Can be taken at bedtime to lessen dangers from sedative effect. Take with food if GI distress occurs. Avoid taking with alcohol or CNS depressants. Common side effects include drowsiness, dry mouth, hypotension, delayed micturition. Pregnancy category: UK; PB: 85%-95%; t½: 8-15 h
nortriptyline HCl (Pamelor, Aventyl)	A: PO: Initially 25-50 mg t.i.d./q.i.d.; *max:* 150 mg/d Older adults: PO: Initially 10-25 mg/d h.s.; *max:* 150 mg/d Adol: PO: 1-3 mg/kg/d in 3-4 divided doses or h.s.; *max:* 150 mg/d Therapeutic serum range: 50-150 ng/mL	For depression. Similar to imipramine HCl. Pregnancy category: C; PB: 90%-95%; t½: 16-90 h
protriptyline HCl (Vivactil)	A: PO: Initially 5-10 mg t.i.d.; *max:* 60 mg/d Older adults: Initially 5 mg t.i.d.; *max:* 30 mg/d Therapeutic serum range: 70-250 ng/mL	For depression. Has little sedative effect. May increase suicidal ideation. Effects are similar to imipramine HCl. Pregnancy category: C; PB: 90%; t½: 60-98 h
trimipramine maleate (Surmontil)	A: Initially 75 mg/d in divided doses or h.s.; *max:* 200 mg/d for outpatients, 300 mg/d for inpatients Adol/older adults: Initially 50 mg/d in divided doses or h.s.; *max:* 100 mg/d	For depression. Similar to imipramine HCl. Pregnancy category: C; PB: 95%; t½: 20-26 h
Selective Serotonin Reuptake Inhibitors (SSRIs)		
citalopram (Celexa)	A: PO: 20-40 mg/d; *max:* 40 mg/d Older adults >60 y: PO: 20 mg/d; *max:* 20 mg/d	For depression, panic disorder, obsessive-compulsive disorder. Wait 14 days after stopping MAOIs. May cause sexual dysfunction, insomnia, nausea, and dry mouth. Pregnancy category: C; PB: 80%; t½: 35 h
fluoxetine HCl (Prozac)	See Prototype Drug Chart 28-1.	
paroxetine HCl (Paxil)	Depression: Regular-release tablets A: PO: Initially 20 mg/d; *max:* 50 mg/d Older adults: PO: Initially: 10 mg/d; *max:* 40 mg/d Controlled-release tablets A: PO: Initially 25 mg/d AM; *max:* 62.5 mg/d Older adults: PO: Initially 12.5 mg/d; *max:* 50 mg/d	For depression and obsessive-compulsive disorder. Lower dose for older adults and those with renal and hepatic disorders. Side effects include dizziness, insomnia, headache, nausea, dry mouth, tremors, and postural hypotension. Pregnancy category: D; PB: 95%; t½: 24 h
sertraline HCl (Zoloft)	A: PO: 50 mg/d; *max:* 200 mg/d	For major depressive disorders. Do not take with MAOIs or TCAs. Take with food if GI distress occurs. Urine may be pink-red-brown color. Pregnancy category: C; PB: 98%; t½: 24 h

TABLE 28-2 ANTIDEPRESSANTS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
fluvoxamine (Luvox)	A: PO: 50-200 mg/d; *max:* 300 mg/d C >8 y: PO: 25 mg/d; *max:* 300 mg/d	For obsessive-compulsive disorder and social anxiety disorder. Caution: Do not use with renal or hepatic disorder. Pregnancy category: C; PB: 77%; t½: 15 h
escitalopram (Lexapro)	A: PO: 10 mg/d, may increase to 20 mg/d after 1 wk; *max:* 20 mg/d Older adults: PO: 10 mg/d; *max:* 10 mg/d for depression Adol: PO: 10 mg/d; *max:* 20 mg/d	For depression and generalized anxiety disorder. Pregnancy category: C; PB: 80%; t½: 25-35 h
vilazodone (Viibryd)	A: PO: 10 mg/d for 7 d; then 20 mg/d for 7 d; then 40 mg/d	For major depression. Common adverse effects include dizziness, insomnia, diarrhea, nausea, dry mouth, decreased libido. Pregnancy category: C; PB: 96%-97%; t½: 25 h
Atypical (Heterocyclic or Second-Generation) Antidepressants		
amoxapine (Asendin)	A: PO: 50 mg b.i.d./q.i.d.; *max:* 400 for outpatients, 600 for inpatients Older adults: PO: 25 mg b.i.d./q.i.d.; *max:* 300 mg/d	For depression with anxiety and for reactive depression. Do not take with MAOIs. Side effects include drowsiness, dizziness, EPS, postural hypotension, increased appetite, urinary retention. Pregnancy category: C; PB: >90%; t½: 8 h
maprotiline HCl (Ludiomil)	A: PO: 75 mg h.s. or in divided doses; *max:* 150-225 mg/d Older adults: 25 mg h.s.; *max:* 150-225 mg/d	Same as amoxapine. Can be taken at bedtime. Pregnancy category: B; PB: 88%; t½: 27-58 h
trazodone HCl (Desyrel)	A: PO: 150 mg/d in divided doses; *max:* 400 mg/d for outpatients, 600 mg/d for inpatients	For depression. Can be taken at bedtime to lessen dangers from sedative effect. Drowsiness, lightheadedness, postural hypotension, and dry mouth might occur. Take with food to decrease GI distress. Pregnancy category: C; PB: 85%-95%; t½: 5-10 h
Norepinephrine and Dopamine Reuptake Inhibitors (NDRIs)		
bupropion HCl (Wellbutrin)	A: PO: 75-100 mg b.i.d.; *max:* 300 mg/d	For depression, seasonal affective disorder, and nicotine withdrawal. May cause increased risk of seizures. Avoid with a history of seizures. Many side effects. Pregnancy category: B; PB: 84%; t½: 8-24 h
Miscellaneous Antidepressants		
mirtazapine (Remeron)	A: PO: Initially 15 mg h.s., then 15-30 mg/d; *max:* 45 mg/d Older adults: PO: Initially 7.5 mg h.s., then 15-30 mg/d; *max:* 45 mg/d	For depression, anxiety, and insomnia. Increases both norepinephrine and serotonin neurotransmitters. Has low anticholinergic activity. Pregnancy category: C; PB: 85%; t½: 20-40 h
Serotonin and Norepinephrine Reuptake Inhibitors		
desvenlafaxine (Pristiq)—extended-release tablet	A: Extended-release tablet PO: 50 mg/d; *max:* 400 mg/d	For depression, feelings of guilt and worthlessness, and anxiety. Decrease dose with renal and hepatic disorders and for anxiety. Does not cause cardiovascular problems or sedation. Pregnancy category: C; PB: 30%; t½: 11 h
duloxetine (Cymbalta)	A: PO: 40-60 mg/d in single or divided doses; *max:* 60 mg/d	For major depression, diabetic neuropathy, fibromyalgia, generalized affective disorder, musculoskeletal pain, and osteoarthritis. Wait 14 days after stopping MAOIs. Pregnancy category: C; PB: 90%; t½: 12 h
venlafaxine (Effexor)	See Prototype Drug Chart 28-2.	
Monoamine Oxidase Inhibitors (MAOIs)		
isocarboxazid (Marplan)	A: PO: 10-20 mg/d; *max:* 40 mg/d	For depression that is refractory to TCAs. Avoid certain foods such as cheese, sour cream, wine, beer, figs, anchovies, shrimp, bananas, and chocolate, and avoid drugs (e.g., TCAs). Pregnancy category: C; PB: UK; t½: 2.5 h
phenelzine sulfate (Nardil)	A: PO: 15 to 60 mg/d in divided doses; *max:* 90 mg/d	For depression. Avoid certain foods and drugs (see isocarboxazid). Pregnancy category: C; PB: UK; t½: 12 h
tranylcypromine sulfate (Parnate)	A: PO: 30 mg/d in 2 divided doses; *max:* 60 mg/d	For depression. Avoid certain foods and drugs (see isocarboxazid). Pregnancy category: C; PB: 90%; t½: 2.5 h

TABLE 28-2 ANTIDEPRESSANTS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
selegiline HCl (Emsam, Eldepryl)	A: PO: Regular-release: 10 mg/d A: Orally disintegrating tablet: 2.5 mg/d A: Transdermal: 6 mg/d; *max:* 12 mg/d	For major depression. No dietary restrictions are necessary at low doses. Pregnancy category: C; PB: 85%-90%; t½: PO: 10 h; transdermal 2-20.5 h
Mood Stabilizers		
lithium citrate (Eskalith, Lithobid)	See Prototype Drug Chart 28-3.	
carbamazepine (Tegretol)	A: PO: 200 mg b.i.d.; increase to 200 mg/d as needed; *max:* 1600 mg/d Therapeutic serum level: 4-12 mcg/mL	For acute manic and mixed episodes associated with bipolar disorder. Contraindicated in bone marrow depression. Pregnancy category: D; PB: 76%; t½: 25-65 h
divalproex (Valproate, Depakote)	750 mg/d in divided doses b.i.d.; *max:* 3000 mg/d or 60 mg/kg/d	For major depression, bipolar disorder, mania, tonic-clonic seizures, and migraine prophylaxis. Pregnancy category: C; PB: 90%; t½ 6-16 h
lamotrigine (Lamictal)	25 mg/d for 2 weeks, then 50 mg/d for 2 weeks, then 100 mg/d for 3 weeks; thereafter give 200 mg/d	For major depression; partial seizures, and tonic-clonic seizures Pregnancy category: C; PB: 55%; t½ 25-30 h

A, Adult; *adol,* adolescent; *b.i.d.,* twice a day; *C,* child; *CNS,* central nervous system; *d,* day; *EPS,* extrapyramidal symptoms; *GI,* gastrointestinal; *h,* hour; *h.s.,* at bedtime; *IM,* intramuscular; *maint,* maintenance; *MAOIs,* monoamine oxidase inhibitors; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *t.i.d.,* three times a day; *TCAs,* tricyclic antidepressants; *UK,* unknown; *y,* year; *<,* less than; *>,* greater than.

HERBAL ALERT 28-2

Monoamine Oxidase Inhibitors

- Ginseng, ephedra, ma-huang, and St. John's wort may lead to palpitations, heart attack, and hypertensive crisis when taken with antidepressant MAOIs.
- Ginseng may lead to manic episodes when taken in combination with MAOIs such as tranylcypromine sulfate.
- An excessive dose of anise may interfere with MAOIs.
- An increased use of brewer's yeast with MAOIs can increase blood pressure.

In teaching patients about the foods and drugs to avoid when taking MAOIs, some individuals respond better to verbal instructions and education with reinforcement from videos than to printed communications. Herbal Alert 28-2 details herb interactions with MAOIs.

Side Effects and Adverse Reactions

Side effects of MAOIs include CNS stimulation (agitation, restlessness, and insomnia), orthostatic hypotension, and anticholinergic effects.

Nursing Process

Patient-Centered Collaborative Care

Antidepressants

Assessment

- Assess patient's baseline vital signs and weight for future comparison. TCAs should be avoided in patients with cardiovascular disease and hypertension.
- Note patient's liver and renal function by assessing urine output (>1500 mL/d), blood urea nitrogen (BUN), and serum creatinine and liver enzyme levels.
- Obtain a health history of episodes of depression; assess mental status, and assess for suicidal tendencies.
- Secure a drug history of the current drugs, alcohol, and herbs patient is taking. CNS depressants can cause an additive effect. Antidepressants that cause anticholinergic-like symptoms are contraindicated if patient has glaucoma.
- Assess for tardive dyskinesia and neuroleptic malignant syndrome (NMS), including hyperpyrexia, muscle rigidity, tachycardia, and cardiac dysrhythmias.

Nursing Diagnoses

- Risk for self-directed violence and injury related to feelings of despair
- Anxiety related to situational crises
- Social isolation related to feelings of sadness
- Ineffective coping related to negative thought patterns
- Hopelessness related to feelings of despair
- Deficient knowledge related to inexperience with medication
- Ineffective health maintenance related to lack of interest

Planning

- Patient's depression or bipolar behavior will be decreased.

Nursing Interventions

- Observe patient for signs and symptoms of depression: mood changes, insomnia, apathy, or lack of interest in activities.

- Monitor patient's vital signs. Orthostatic hypotension is common. Check for anticholinergic-like symptoms: dry mouth, increased heart rate, urinary retention, or constipation. Check weight two to three times per week.
- Monitor patient for suicidal tendencies when marked depression is present.
- Observe patient for seizures when patient is taking an anticonvulsant; antidepressants lower the seizure threshold. The anticonvulsant dose might need to be increased.
- Monitor for drug-drug and food-drug interactions. Sympathomimetic-like drugs and foods containing tyramine may cause a hypertensive crisis if taken with MAOIs.
- Check patient for extremely high blood pressure when taking MAOIs.
- Provide patient with a list of foods to avoid when taking MAOIs to avoid hypertensive crisis. These foods include cheese, red wine, beer, liver, bananas, yogurt, and sausage.

Patient Teaching

General

- Teach patient to take the medication as prescribed. Compliance is important.
- Inform patient that full effectiveness of drug may not be evident until 1 to 2 weeks after start of therapy.
- Encourage patient to keep medical appointments.
- Caution patient not to consume alcohol or any CNS depressants because of their addictive effect.
- Inform patient that many herbal products interact with antidepressants, especially MAOIs and SSRIs. Herbs may need to be discontinued, or the antidepressant drug dosage may need to be modified (see Herbal Alerts 28-1 and 28-2).
- Warn patient not to drive or be involved in potentially dangerous mechanical activity until stabilization of drug dose has been established.
- Advise patient not to abruptly stop taking the drug. Drug dose should be gradually decreased by health care provider.
- Encourage patient who is planning pregnancy to consult with health care provider about possible teratogenic effects of the drug on the fetus.
- Take with food if gastrointestinal (GI) distress occurs.

Side Effects

- Advise patient that antidepressants may be taken at bedtime to decrease dangers from the sedative effect. Have patient check with health care provider. Transient side effects include nausea, drowsiness, headaches, and nervousness.

Cultural Considerations

- Explain to Asian patients taking an antipsychotic (such as TCA or lithium) that the dose may need to be decreased. Explain to Hispanic patients that the dose for the antidepressant may be lower than is required for other cultural groups.

Evaluation

- Evaluate the effectiveness of the drug therapy regarding whether patient's depression is controlled or has ceased.

MOOD STABILIZERS

Mood stabilizers are used to treat bipolar affective disorder. Lithium was the first drug used to manage this disorder. Some refer to lithium as an *antimania drug* that is effective in controlling manic behavior that arises from underlying bipolar disorder. Lithium has a calming effect but may cause some memory loss and confusion. It controls any evidence of flight of ideas and hyperactivity. If the person stops taking lithium, manic behavior may return. Lithium (Lithobid), carbamazepine (Tegretol), valproic acid or divalproex (Depakote, Valproate), and lamotrigine (Lamictal) are currently first-line drugs for bipolar disorder.

Lithium is an inexpensive drug that must be closely monitored. Lithium has a narrow therapeutic serum range: 0.5 to 1.5 mEq/L. Serum lithium levels greater than 1.5 to 2 mEq/L are toxic. The serum lithium level should be monitored biweekly until the therapeutic level has been obtained and then monitored monthly on the maintenance dose. Serum sodium levels also need to be monitored because lithium tends to deplete sodium. Lithium must be used with caution, if at all, by patients taking diuretics. Prototype Drug Chart 28-3 lists the pharmacologic behavior of lithium.

Pharmacokinetics More than 95% of lithium is absorbed through the GI tract. The average half-life of lithium is 24 hours; however, in older adults the half-life can be up to 36 hours. Because of its long half-life, cumulative drug action may result. Lithium is metabolized by the liver, and most of the drug is excreted unchanged in the urine.

Pharmacodynamics Lithium is prescribed mostly for the stabilization of bipolar affective disorder. The onset of action is fast, but the patient may not achieve the desired effect for 5 to 6 days. Increased sodium intake increases renal excretion, so the sodium intake needs to be closely monitored. Increased urine output can result in body fluid loss and dehydration. Adequate fluid intake of 1 to 2 L should be maintained daily.

Anticonvulsants, such as carbamazepine (Tegretol), lamotrigine (Lamictal), and divalproex/valproic acid (Depakote) have been used in place of lithium for some patients. These agents are further discussed in Chapter 22. The antipsychotic drugs olanzapine (Zyprexa), ziprasidone (Geodon), and aripiprazole (Abilify) are approved to treat acute mania and mixed episodes of bipolar disorder. Antipsychotic drugs are discussed further in Chapter 27.

Side Effects and Adverse Reactions

The many side effects of lithium—dry mouth, thirst, increased urination (loss of water and sodium), weight gain, bloated feeling, metallic taste, and edema of the hands and ankles—can be annoying to the patient. If taken during pregnancy, lithium may have teratogenic effects.

Lithium and nonsteroidal antiinflammatory drugs (NSAIDs) should *not* be given together on a continuous basis

PROTOTYPE DRUG CHART 28-3

Lithium

Drug Class

Mood stabilizer

Trade Names: Eskalith, Lithane, Lithonate, Lithobid, 🍁 Carbolith, Lithizine

Pregnancy Category: D

Dosage

A: PO: initially 600 mg t.i.d.; maint: 300 mg t.i.d./q.i.d.; *max:* 2.4 g/d

C: PO: 15 to 20 mg/kg/d in 3-4 divided doses

Therapeutic drug range: 0.5-1.5 mEq/L

Contraindications

Liver and renal disease, pregnancy, lactation, severe cardiovascular disease, severe dehydration, hyponatremia, children <12 y

Caution: Thyroid disease, seizure disorder

Drug-Lab-Food Interactions

Drug: May increase lithium level with thiazide diuretics, methyldopa, haloperidol, NSAIDs, antidepressants, carbamazepine, calcium channel blockers, spironolactone, ACE inhibitors, sodium bicarbonate, phenothiazines

May increase lithium excretion with theophylline, aminophylline

May increase risk of serotonin syndrome with SSRIs and SNRIs

May increase hyperglycemia with antidiabetics

Caffeine may decrease lithium levels

Amphetamines may increase risk of mania

Lab: Increase urine and blood glucose, protein; decrease serum sodium level

Food: Increase sodium intake; lithium may cause sodium depletion

Herbs: Use of St. John's wort, kava kava, and valerian may lead to neurotoxicity

Pharmacokinetics

Absorption: PO: well absorbed

Distribution: PB: UK

Metabolism: t½: 21-30 h

Excretion: 98% in urine, mostly unchanged

Pharmacodynamics

PO: Onset: UK

Peak: 2-4 h

Duration: 24 h

Therapeutic Effects/Uses

To treat bipolar psychosis, manic episodes

Mode of Action: Alteration of ion transport in muscle and nerve cells; increased receptor sensitivity to serotonin

Side Effects

Headache, memory impairment, blurred vision, metallic taste, dental caries, lethargy, drowsiness, dizziness, tremors, slurred speech, dry mouth, anorexia, vomiting, diarrhea, polyuria, dehydration, hypotension, abdominal pain, muscle weakness, restlessness

Adverse Reactions

Urinary and fecal incontinence, hyperglycemia, hyponatremia, proteinurea, polyurea, leukocytosis, nephrotoxicity

Life-threatening: Cardiac dysrhythmias, seizures, cardiac arrest, serotonin syndrome, neuroleptic malignant syndrome

A, Adult; *C,* child; *d,* day; *h,* hour; *max,* maximum; *NSAIDs,* nonsteroidal antiinflammatory drugs; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *SR,* sustained-release; *t.i.d.,* three times a day; *t ½,* half-life; *UK,* unknown; *<,* less than; *>,* greater than; 🍁, Canadian drug name.

and should not be prescribed for patients who have a cardiac "sick sinus syndrome." If the patient has taken lithium for a long period, laboratory tests to determine thyroid function should be closely monitored.

Nursing Process
Patient-Centered Collaborative Care

Mood Stabilizer: Lithium

Assessment

- Assess for suicidal ideation.
- Assess patient's baseline vital signs for future comparison.
- Evaluate patient's neurologic status, including gait, level of consciousness, reflexes, and tremors.
- Note patient's hepatic and renal function by assessing urine output (>600 mL/d) and whether BUN and serum creatinine and liver enzyme levels are within normal range. Assess for toxicity. Draw weekly blood levels initially and then every 1 to 2 months. Therapeutic serum levels for acute mania are 1 to 1.5 mEq/L; for maintenance, levels are 0.5 to 1.5 mEq/L. Signs and symptoms of toxicity at serum levels of 1.5 to 2 mEq/L are persistent nausea and vomiting, severe diarrhea, ataxia, blurred vision, and tinnitus. At 2 to 3.5 mEq/L, signs and symptoms of toxicity are excessive output of dilute urine, increasing tremors, muscular irritability, psychomotor retardation, mental confusion, and giddiness. At 3.5 mEq/L or higher, levels are life-threatening and may result in impaired consciousness, nystagmus, seizures, coma, oliguria/anuria, cardiac dysrhythmias, myocardial infarction, and cardiovascular collapse.

Withhold medication and notify health care provider immediately if any of these occur.

- Obtain a health history of episodes of depression or manic-depressive behavior.
- Obtain patient's drug history. Diuretics, NSAIDs (e.g., ibuprofen), tetracyclines, methyldopa, and probenecid decrease renal clearance of lithium, causing drug accumulation.

Nursing Diagnoses

- Risk for injury or violence related to impulsiveness
- Ineffective coping related to manic behavior
- Noncompliance related to lack of adequate education regarding lithium

Planning

- Patient's manic-depressive behavior will be decreased.

Nursing Interventions

- Observe patient for signs and symptoms of depression: mood changes, insomnia, apathy, or lack of interest in activities.
- Monitor patient's vital signs. Orthostatic hypotension is common.
- Draw blood samples for lithium levels immediately before the next dose (8 to 12 hours after the previous dose).
- Monitor for signs of lithium toxicity. Report high (greater than 1.5 mEq/L) and toxic (greater than 2.0 mEq/L) serum lithium levels immediately to health care provider.
- Monitor patient for suicidal tendencies when marked depression is present.
- Evaluate patient's urine output and body weight. Fluid volume deficit may occur as a result of polyuria.
- Observe patient for fine- and gross-motor tremors and presence of slurred speech, which are signs of adverse reaction.
- Check patient's cardiac status. Loss of fluids and electrolytes may cause cardiac dysrhythmias.
- Monitor patient's serum electrolytes. Report abnormal findings.

Patient Teaching

General

- Teach patient to take lithium as prescribed. Emphasize importance of adherence to the therapy, laboratory tests, and follow-up visits with health care provider. If lithium is stopped, manic symptoms will reappear.
- Encourage patient to keep medical appointments. Have patient check with health care provider before taking OTC preparations.
- Warn patient not to drive a motor vehicle or be involved in potentially dangerous mechanical activity until stable lithium level is established.
- Advise patient to maintain adequate fluid intake: 2 to 3 L/d initially and 1 to 2 L/d maintenance. Fluid intake should increase in hot weather.
- Teach patient to take lithium with meals to decrease gastric irritation.
- Inform patient that effectiveness of drug may not be evident until 1 to 2 weeks after the start of therapy. Compliance in taking the prescribed lithium doses on a daily basis is a major problem with bipolar patients. When patient has a period of emotional stability, he or she does not believe that the drug is needed; thus, patient stops taking the lithium.
- Advise patient who is planning pregnancy to consult with health care provider about possible teratogenic effects of the drug on the fetus, especially during the first 3 months.
- Encourage patient to wear or carry an identification tag or bracelet indicating the drug taken.

Diet

- Inform patient to avoid caffeine products (coffee, tea, cola), because they can aggravate the manic phase of bipolar disorder.
- Advise patient to maintain adequate sodium intake and to avoid crash diets that affect physical and mental health.

Side Effects

- Advise patient to contact health care provider if experiencing symptoms of toxicity. Early symptoms include diarrhea, drowsiness, loss of appetite, muscle weakness, nausea, vomiting, slurred speech, trembling. Late symptoms include blurred vision, confusion, increased urination, convulsions, severe trembling, and unsteadiness.

Cultural Considerations

- Obtain an interpreter when necessary; do not rely on family members, who may not fully disclose because of honor, shame, or lack of understanding of medical terminology.

Evaluation

- Evaluate the effectiveness of the drug therapy. Patient is free of bipolar behavior.
- Allow patient to verbalize understanding of symptoms of toxicity.
- Determine if patient demonstrates a subsiding or resolution of symptoms.

CRITICAL THINKING CASE STUDY

ST, a 37-year-old woman, is receiving fluoxetine (Prozac) 20 mg in the evening for depression. ST complains of insomnia and GI upset.

1. What could you suggest to ST to help her avoid insomnia? Explain your answer.
2. How might ST avoid GI upset when taking fluoxetine?

   ST states that she does not think the fluoxetine is helping. She states that she has heard about herbal supplements that may be taken for depression. She has also heard that fluoxetine can be taken weekly.
3. Is ST's fluoxetine dose within normal dosage range? Explain your answer.
4. How would you respond to ST about the use of certain herbal supplements for depression?
5. What would your response be concerning the use of fluoxetine in a weekly dose?

NCLEX STUDY QUESTIONS

1. A patient is admitted with bipolar affective disorder. The nurse acknowledges that which medication is used to treat this disorder for some patients in place of lithium?
   a. thiopental
   b. gingko biloba
   c. fluvoxamine (Luvox)
   d. divalproex (Depakote)
2. The nurse realizes that some herbs interact with selective serotonin reuptake inhibitors. Which herb interaction may cause serotonin syndrome?
   a. feverfew
   b. ma-huang
   c. St. John's wort
   d. gingko biloba
3. A selective serotonin reuptake inhibitor (SSRI) is prescribed for a patient. The nurse knows that which drug is an SSRI?
   a. paroxetine (Paxil)
   b. amitriptyline (Elavil)
   c. divalproex sodium (Depakote)
   d. bupropion HCl (Wellbutrin)
4. A patient is taking tranylcypromine sulfate (Parnate) for depression. What advice should the nurse include in the teaching plan for this medication?
   a. Warn the patient about severe hypotension.
   b. Instruct the patient to avoid beer and cheddar cheese.
   c. Encourage the patient to take ginseng and ephedra.
   d. Encourage the patient to eat fruit such as bananas.
5. Which statement is true concerning lithium?
   a. The maximum dose is 3.4 g/d.
   b. The therapeutic drug range is 2.5 to 3.5 mEq/L.
   c. Lithium increases receptor sensitivity to GABA.
   d. Concurrent NSAIDs may increase lithium levels.
6. When a patient is taking an antidepressant, what should the nurse do? (Select all that apply.)
   a. Monitor the patient for suicidal tendencies.
   b. Observe the patient for orthostatic hypotension.
   c. Teach the patient to take the drug with food if GI distress occurs.
   d. Tell the patient that the drug may not have full effectiveness for 1 to 2 weeks.
   e. Advise the patient to maintain adequate fluid intake of 2 L/d.
7. A patient is taking lithium. The nurse should be aware of the importance of which nursing intervention(s)? (Select all that apply.)
   a. Observe the patient for motor tremors.
   b. Monitor the patient for orthostatic hypotension.
   c. Draw lithium blood levels immediately after a dose.
   d. Advise the patient to drink 750 mL/d of fluid in hot weather.
   e. Advise the patient to avoid caffeinated foods and beverages.
   f. Teach the patient to take lithium with meals to decrease gastric irritation.

Answers: 1, d; 2, c; 3, a; 4, b; 5, d; 6, a, b, c, d; 7, a, b, e, f.

UNIT IX

Antibacterial and Antiinfective Agents

Disease-producing microorganisms may be gram-positive or gram-negative bacteria, viruses, or fungi. The degree to which they are pathogenic depends on the microorganism and its virulence. The cell walls of bacteria differ in their structure: bacilli are elongated, cocci are spherical, and spirilla are helical.

This unit discusses agents prescribed to combat disease-producing microorganisms. Included are antibacterials-antibiotics (penicillins, cephalosporins, macrolides, tetracyclines, aminoglycosides, fluoroquinolones) and sulfonamides.

Chapter 29 discusses penicillins and cephalosporins; Chapter 30 addresses macrolides, tetracyclines, aminoglycosides, and fluoroquinolones; and Chapter 31 focuses on the sulfonamides.

CHAPTER 29

Penicillins and Cephalosporins

- Unfolding Case Studies

OBJECTIVES

- Explain the mechanisms of action of antibacterial drugs.
- Differentiate between bacteria that are naturally resistant and those that have acquired resistance to an antibiotic.
- Summarize the three general adverse effects associated with antibacterial drugs.
- Differentiate between narrow-spectrum and broad-spectrum antibiotics.
- Compare the effects of the natural, broad-spectrum (extended), penicillinase-resistant, and antipseudomonal penicillins.
- Contrast the effects of first-, second-, third-, and fourth-generation cephalosporins.
- Apply the nursing process for patients receiving penicillins and cephalosporins.

This chapter discusses the antibacterials and their effects, which include mechanisms of antibacterial action, body defenses, resistance to antibacterials, use of antibacterial combinations, general adverse reactions to antibacterials, and narrow- and broad-spectrum antibiotics. This chapter also discusses two antibacterials in detail: penicillin and cephalosporin.

PATHOPHYSIOLOGY

Bacteria, known as *prokaryotes,* are single-celled organisms lacking a true nucleus and nuclear membrane. Most bacteria have a rigid cell wall, and the structure of the cell wall determines the shape of the bacteria. One classification of bacteria involves the appearance or shape under a microscope. A *bacillus* is a rod-shaped organism. *Cocci* are spherical. When cocci appear in clusters, they are called *staphylococci;* when cocci are arranged in chains, they are called *streptococci.* Bacteria reproduce by cell division about every 20 minutes.

Another classification of bacteria involves staining properties of the cell. The Gram staining method was devised in 1882 by Hans Christian Gram, a Danish bacteriologist. Gram staining is determined by the ability of the bacterial cell wall to retain a purple stain by a basic dye. Crystal violet is normally used in the staining process but may be substituted with methylene blue. If bacteria retain a purple stain, they are classified as *gram-positive* microorganisms. Those bacteria not stained are known as *gram-negative* microorganisms. Examples of gram-positive bacteria include *Staphylococcus aureus, Streptococcus pneumoniae, Group B streptococcus,* and *Clostridium perfringens.* Examples of gram-negative bacteria include *Neisseria meningitides, Escherichia coli,* and *Haemophilus influenzae.*

Bacteria produce toxins that cause cell lysis (cell death). Many bacteria produce the enzyme beta-lactamase, which destroys beta-lactam antibiotics such as penicillins and cephalosporins.

ANTIBACTERIAL DRUGS

Antibacterials/Antibiotics

Although the terms *antibacterial, antimicrobial,* and *antibiotic* are frequently used interchangeably, there are some subtle differences in meaning. **Antibacterials** and **antimicrobials** are substances that inhibit bacterial growth or kill bacteria and other **microorganisms** (microscopic organisms including viruses, fungi, protozoa, and rickettsiae). Technically, the term *antibiotic* refers to chemicals produced by one kind of microorganism that inhibits the growth of or kills another. For practical purposes, however, these terms may be used interchangeably. Several drugs, including antiinfective and chemotherapeutic agents, have actions similar to those of antibacterial and antimicrobial agents. Antibacterial drugs do not act alone in destroying bacteria. Natural body defenses, surgical procedures to excise infected tissues, and dressing changes may be needed along with antibacterial drugs to eliminate the infecting bacteria.

Antibacterial drugs are either obtained from natural sources or manufactured. The use of moldy bread on wounds to fight infection dates back 3500 years. In 1928, a British bacteriologist named Alexander Fleming noted that “mold” was contaminating his bacterial cultures and inhibiting bacterial growth. The mold was called *Penicillium notatum;* thus Fleming called the substance *penicillin.* In 1939 Howard Florey expanded on Fleming’s findings and purified the penicillin so it could be used commercially. Penicillin was used during World War II and marketed in 1945. Sulfonamide, a synthetic antibacterial, was introduced in 1935. Sulfonamides are discussed in greater detail in Chapter 31.

Bacteriostatic drugs inhibit the growth of bacteria, whereas **bactericidal** drugs kill bacteria. Some antibacterial drugs (tetracycline and sulfonamides) have a bacteriostatic effect, whereas other antibacterials (penicillins and cephalosporins) have a bactericidal effect. Depending on the drug dose and serum level, certain drugs can have both bacteriostatic and bactericidal effects.

For drugs with a narrow therapeutic index (e.g., aminoglycosides), peaks and troughs of serum antibiotic levels are monitored to determine if the drug is within the therapeutic range for its desired effect. If the serum *peak* level is too high, drug toxicity could occur. If the serum *trough* level (drawn minutes before administration of the next drug dose) is below the therapeutic range, the patient is not receiving an adequate antibiotic dose to kill the targeted microorganism.

Mechanisms of Antibacterial Action

Five mechanisms of antibacterial action are responsible for the inhibition of growth or destruction of microorganisms: (1) inhibition of bacterial cell-wall synthesis, (2) alteration of membrane permeability, (3) inhibition of protein synthesis, (4) inhibition of the synthesis of bacterial ribonucleic acid (RNA) and deoxyribonucleic acid (DNA), and (5) interference with metabolism within the cell (Table 29-1).

Pharmacokinetics Antibacterial drugs must not only penetrate the bacterial cell wall in sufficient concentration, but also must have an affinity (attraction) to the binding sites on the bacterial cell. The time the drug remains at the binding sites increases the effect of the antibacterial action. This time factor is controlled by the pharmacokinetics (distribution, half-life, and elimination) of the drug.

Antibacterials that have a longer half-life usually maintain a greater concentration at the binding site; therefore, frequent dosing is not required. Most antibacterials are not highly protein-bound, with a few exceptions (e.g., oxacillin, ceftriaxone, cefoperazone, cefprozil, cloxacillin, nafcillin, clindamycin). Protein binding does not have a major influence on the effectiveness of most antibacterial drugs. The steady state of the antibacterial drug occurs after the fourth to fifth half-lives, and the drug is eliminated from the body, mainly through urine, after the seventh half-life.

Pharmacodynamics The drug concentration at the site or the exposure time for the drug plays an important role in bacterial eradication. Antibacterial drugs are used to achieve the minimum effective concentration (MEC) necessary to halt the growth of a microorganism. Many antibacterials have a bactericidal effect against the pathogen when the drug concentration remains constantly above the MEC during the dosing interval. Duration of time for use of the antibacterial varies according to the type of pathogen, site of infection, and immunocompetence of the host. With some severe infections, a continuous infusion regimen is more effective than intermittent dosing because of constant drug concentration and time exposure. Once-daily antibacterial dosing (e.g., aminoglycosides, macrolides, fluoroquinolones) has been effective in eradicating pathogens and has not caused severe adverse reactions (ototoxicity, nephrotoxicity) in most cases. The ease of compliance with once- or twice-daily drug dosing also increases the patient’s adherence to the drug regimen.

Figure 29-1 illustrates the effect of three methods of drug dosing. The drug dose is effective when it remains above the MEC.

Body Defenses

Body defenses and antibacterial drugs work together to stop the infectious process. The effect that antibacterial drugs have on an infection depends not only on the drug but also on the host’s defense mechanisms. Factors such as age, nutrition, immunoglobulins, white blood cells (WBCs), organ function, and circulation influence the body’s ability to fight infection.

TABLE 29-1 MECHANISMS OF ACTIONS OF ANTIBACTERIAL DRUGS

ACTION	EFFECT	DRUGS
Inhibition of cell wall synthesis	Bactericidal effect Enzyme breakdown of cell wall Inhibition of enzyme in synthesis of cell wall.	penicillin cephalosporins bacitracin vancomycin
Alteration in membrane permeability	Bacteriostatic or bactericidal effect Increases membrane permeability. Loss of cellular substances causes lysis of the cell.	amphotericin B nystatin polymyxin colistin
Inhibition of protein synthesis	Bacteriostatic or bactericidal effect Interferes with protein synthesis without affecting normal cell. Inhibits steps of protein synthesis.	aminoglycosides tetracyclines erythromycin lincomycin
Inhibition of synthesis of bacterial RNA and DNA	Inhibits synthesis of RNA and DNA in bacteria. Binds to nucleic acid and enzymes needed for nucleic acid synthesis.	fluoroquinolones
Interference with cellular metabolism	Bacteriostatic effect Interferes with steps of metabolism within cells.	sulfonamides trimethoprim isoniazid (INH) nalidixic acid rifampin

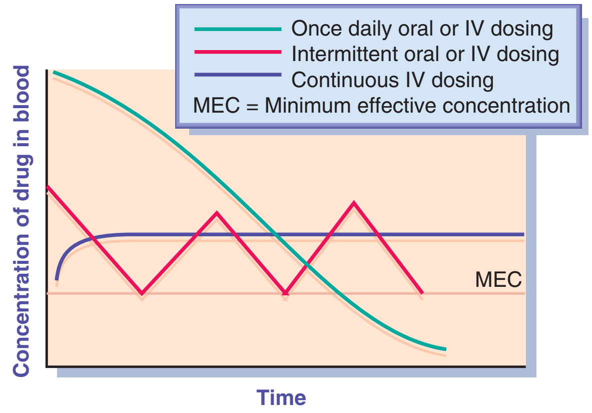

FIGURE 29–1 Effects of concentrated drug dosing.

Older adults and undernourished individuals have less resistance to infection than younger, well-nourished populations. If the host's natural body defense mechanisms are inadequate, drug therapy might not be as effective. As a result, drug therapy may need to be closely monitored or revised. When circulation is impeded, an antibacterial drug may not be distributed properly to the infected area. In addition, **immunoglobulins** (antibody proteins such as IgG and IgM) and other elements of the immune response system (WBCs) needed to combat infections may be depleted in individuals with poor nutritional status.

Resistance to Antibacterials

Bacteria may be sensitive or resistant to certain antibacterials. When bacteria are sensitive to a drug, the pathogen is inhibited or destroyed. If bacteria are resistant to an antibacterial, the pathogen continues to grow, despite administration of that antibacterial drug.

Bacterial resistance may result naturally **(inherent resistance)** or it may be acquired. A natural, or inherent, resistance occurs without previous exposure to the antibacterial drug. For example, the gram-negative (non–gram-staining) bacterium *Pseudomonas aeruginosa* is inherently resistant to penicillin G. An **acquired resistance** is caused by prior exposure to the antibacterial. Although *Staphylococcus aureus* was once sensitive to penicillin G, repeated exposures have caused this organism to evolve and become resistant to it. Penicillinase, an enzyme produced by the microorganism, is responsible for causing its penicillin resistance. Penicillinase metabolizes penicillin G, causing the drug to be ineffective. Penicillinase-resistant penicillins that are effective against *S. aureus* are available.

Antibiotic resistance is a major problem. In the early 1980s, pharmaceutical companies thought that enough antibiotics were on the market, so these companies concentrated on developing antiviral and antifungal drugs. As a result, fewer new antibiotics were developed during the 1980s. Now pharmaceutical companies have developed many new antibiotics, but antibiotic resistance continues to develop, especially when antibiotics are used frequently. As bacteria reproduce, some mutation occurs, and eventually the mutant bacteria survive the effects of the drug. One explanation is that the mutant bacteria strain may have grown a thicker cell wall.

In large health care institutions, there is a tendency toward drug resistance in bacteria. Mutant strains of organisms have developed, thus increasing their resistance to antibiotics that were once effective against them. Infections acquired while patients are hospitalized are called **nosocomial infections.** Many of these infections are caused by drug-resistant bacteria and can prolong hospitalization, which is costly to both the patient and third-party health care insurers.

Another problem related to antibiotic resistance is that bacteria can transfer their genetic instruction to another bacterial species. The other bacterial species becomes resistant to that antibiotic as well. Bacteria can pass along high resistance to a more virulent and aggressive bacterium (e.g., *S. aureus,* enterococci).

Methicillin (Staphcillin) was the first penicillinase-resistant penicillin developed in 1959 in response to a resistance of *S. aureus.* In 1968, strains of *S. aureus* were beginning to become resistant to methicillin. Highly resistant bacteria, known as methicillin-resistant *Staphylococcus aureus* (MRSA), became resistant not only to methicillin, but to all penicillins and cephalosporins as well. Resistance that was once found only in hospitals began to emerge in 1981 in the community as well. Methicillin is now off the market. The treatment of choice for MRSA is vancomycin (Vancocin). Other effective drugs used to treat MRSA include linezolid (Zyvox), daptomycin (Cubicin), trimethoprim/sulfamethoxazole (Bactrim), doxycycline (Vibramycin), and clindamycin (Cleocin). Telavancin (Vibativ), a glycopeptides antiinfective, was approved in September 2009 to treat gram-negative bacteria, including MRSA.

Many enterococcal strains are resistant to penicillin, ampicillin, gentamicin, streptomycin, and vancomycin. Another big resistance problem is vancomycin-resistant *Enterococcus faecium* (VREF), which can cause death in many persons with weakened immune systems. The incidence of VREF in hospitals has increased. A strain of MRSA has been reported to be resistant to vancomycin (vancomycin-resistant *Staphylococcus aureus,* or VRSA). Major medical problems result. One antibiotic after another is ineffective against new resistant strains of bacteria. As new drugs are developed, drug resistance will probably develop as well. Pharmaceutic companies and biotechnical firms are working on new classes of drugs to overcome the problem of bacterial resistance to antibiotics. A class of antibiotics, oxazolidinones, was discovered by a pharmaceutical company in 1988, but the company could not overcome toxicity problems in this class of drug. Another pharmaceutical company has taken the compound and made it less toxic. This antibiotic, linezolid, is effective against MRSA, VREF, and penicillin-resistant *Streptococci*. Quinupristin/dalfopristin (Synercid), which consists of two streptogramin antibacterials, is marketed in a combination of 30 : 70 for intravenous (IV) use against life-threatening infection caused by VREF and for treatment of bacteremia, *S. aureus,* and *Streptococcus pyogenes.*

Another way to attack antimicrobial resistance is to develop drugs that disable the antibiotic-resistant mechanism in the bacteria. Patients would take the antibiotic-resistance disabler along with the antibiotic already on the market, making the drug effective again. Developing a bacterial vaccine is another way to combat bacteria and lessen the need for antibiotics. The bacterial vaccine against pneumococcus has been effective in decreasing the occurrence of pneumonia and meningitis among various age groups.

Antibiotic misuse, a major problem today, increases antibiotic resistance. Studies reveal that 23% to 37.8% of patients in hospitals receive antibiotics and 50% of this population is receiving antibiotics inappropriately. When antibiotics are taken unnecessarily (e.g., for viral infections, when no infection is present) or incorrectly (e.g., skipping doses, not taking the full antibiotic regimen), one may develop resistance to antibacterials. Consumer education is important because many patients "demand" antibiotics for viral conditions. Antibiotics are ineffective against viruses. However, viral infections that persist could decrease the body's immune system, thus promoting a bacterial infection. The nurse should teach patients about the proper use of antibiotics to prevent situations that promote drug resistance to bacteria.

Cross-resistance can also occur between antibacterial drugs that have similar actions, such as the penicillins and cephalosporins. To ascertain the effect antibacterial drugs have on a specific microorganism, culture and sensitivity or antibiotic susceptibility laboratory testing is performed. A *culture and sensitivity* test (C&S) can detect the infective microorganism present in a sample (e.g., blood, sputum, swab) and what drug can kill it. The organism causing the infection is determined by culture, and the antibiotics the organism is sensitive to are determined by sensitivity. The susceptibility or resistance of one microorganism to several antibacterials can be determined by this method. Multiantibiotic therapy (daily use of several antibacterials) delays the development of microorganism resistance.

Use of Antibiotic Combinations

Combination antibiotics should not be routinely prescribed or administered except for specific uncontrollable infections. Usually a single antibiotic will successfully treat a bacterial infection. When there is a severe infection that persists and is of unknown origin or has been unsuccessfully treated with several single antibiotics, a combination of two or three antibiotics may be suggested. Before beginning antibiotic therapy, a culture or cultures should be taken to identify the bacteria.

When two antibiotics are combined, the result is additive, potentiative, or antagonistic. The *additive* effect is equal to the sum of the effects of two antibiotics. The *potentiative* effect occurs when one antibiotic potentiates the effect of the second antibiotic, increasing their effectiveness. The *antagonistic* result is a combination of a drug that is bactericidal, such as penicillin, and a drug that is bacteriostatic, such as tetracycline. When these two drugs are used together, the desired effect may be greatly reduced.

General Adverse Reactions to Antibacterials

Three major adverse reactions associated with the administration of antibacterial drugs are allergic (hypersensitivity) reactions, superinfection, and organ toxicity. Table 29-2 describes these adverse reactions, all of which require close monitoring of the patient.

Narrow-Spectrum and Broad-Spectrum Antibiotics

Antibacterial drugs are either narrow spectrum or broad spectrum. The **narrow-spectrum antibiotics** are primarily effective against one type of organism. For example, penicillin and erythromycin are used to treat infections caused by gram-positive bacteria. Certain **broad-spectrum antibiotics** (tetracycline and cephalosporins) can be effective against both gram-positive and gram-negative organisms. Because narrow-spectrum antibiotics are selective, they are more active against those single organisms than the broad-spectrum antibiotics. Broad-spectrum antibiotics are frequently used to treat infections when the offending microorganism has not been identified by C&S.

TABLE 29-2 GENERAL ADVERSE REACTIONS TO ANTIBACTERIAL DRUGS

TYPE	CONSIDERATIONS
Allergy or hypersensitivity	Allergic reactions to drugs may be mild or severe. Examples of mild reactions are rash, pruritus, and hives. An example of a severe response is anaphylactic shock. Anaphylaxis results in vascular collapse, laryngeal edema, bronchospasm, and cardiac arrest. Shortness of breath is frequently the first symptom of anaphylaxis. Severe allergic reaction generally occurs within 20 minutes. Mild allergic reaction is treated with an antihistamine; anaphylaxis requires treatment with epinephrine, bronchodilators, and antihistamines.
Superinfection	Superinfection is a secondary infection that occurs when the normal microbial flora of the body are disturbed during antibiotic therapy. Superinfections can occur in the mouth, respiratory tract, intestine, genitourinary tract, or skin. Fungal infections frequently result in superinfections, although bacterial organisms (e.g., *Proteus, Pseudomonas,* staphylococci) may be the offending microorganisms. Superinfections rarely develop when the drug is administered for less than 1 week. They occur more commonly with the use of broad-spectrum antibiotics. For fungal infection of the mouth, nystatin is frequently used.
Organ toxicity	The liver and kidneys are involved in drug metabolism and excretion. Antibacterials may result in damage to these organs. For example, aminoglycosides can be *nephrotoxic* (as well as ototoxic).

PENICILLINS AND CEPHALOSPORINS

Penicillins

Penicillin, a natural antibacterial agent obtained from the mold genus *Penicillium,* was introduced to the military during World War II and is considered to have saved many soldiers' lives. It became widely used in 1945 and was labeled a "miracle" drug. With the advent of penicillin, many patients survived who would have normally died from wound and severe respiratory infections.

Penicillin's beta-lactam structure (beta-lactam ring) interferes with bacterial cell-wall synthesis by inhibiting the bacterial enzyme that is necessary for cell division and cellular synthesis. The bacteria die of cell lysis (cell breakdown). The penicillins can be both bacteriostatic and bactericidal, depending on the drug and dosage. Penicillin G is primarily bactericidal.

Penicillins are mainly referred to as *beta-lactam antibiotics.* Bacteria can produce a variety of enzymes, such as beta-lactamases, that can inactivate penicillin and other beta-lactam antibiotics such as the cephalosporins. The beta-lactamases, which attack penicillins, are called *penicillinases.*

Penicillin G was the first penicillin administered orally and by injection. With oral administration, only about one third of the dose is absorbed. Because of its poor absorption, penicillin G given by injection (intramuscular [IM] and intravenous [IV]) is more effective in achieving a therapeutic serum penicillin level. Aqueous penicillin G has a short duration of action, and the IM injection is very painful, because it is an aqueous drug solution. As a result, a longer-acting form of penicillin, procaine penicillin (milky color), was produced to extend the activity of the drug. Procaine in the penicillin decreases the pain related to injection.

Penicillin V was the next type of penicillin produced. Although two thirds of the oral dose is absorbed by the gastrointestinal (GI) tract, it is a less potent antibacterial drug than penicillin G. Penicillin V is effective against mild to moderate infections, including anthrax as a biologic weapon of bioterrorism.

Initially penicillin was overused. It was first introduced for the treatment of staphylococcal infections, but after a few years mutant strains of *Staphylococcus* developed that were resistant to penicillins G and V because of the bacterial enzyme penicillinase, which destroys penicillin. This led to the development of new broad-spectrum antibiotics with structures similar to penicillin to combat infections resistant to penicillins G and V.

Food in the stomach does not significantly alter absorption of penicillin V, so it should be taken after meals. Amoxicillins are penicillins that are unaffected by food.

Broad-Spectrum Penicillins (Aminopenicillins)

Broad-spectrum penicillins are used to treat both gram-positive and gram-negative bacteria. They are not, however, as "broadly" effective against all microorganisms as they were once considered to be. This group of drugs is costlier than penicillin and therefore should not be used when ordinary penicillins, such as penicillin G, are effective. The broad-spectrum penicillins are effective against some gram-negative organisms: *Escherichia coli, Haemophilus influenzae, Shigella dysenteriae, Proteus mirabilis,* and *Salmonella.* However, these drugs are not penicillinase resistant. They are readily inactivated by beta-lactamases, thus ineffective against *S. aureus.* Examples of this group are ampicillin (Omnipen), and amoxicillin (Amoxil) (Table 29-3). Amoxicillin is the most prescribed penicillin derivative for adults and children.

Penicillinase-Resistant Penicillins (Antistaphylococcal Penicillins)

Penicillinase-resistant penicillins (antistaphylococcal penicillins) are used to treat penicillinase-producing *S. aureus.* Dicloxacillin is an oral preparation of these antibiotics; nafcillin and oxacillin are IM and IV preparations. This group of drugs is not effective against gram-negative organisms and is less effective than penicillin G against gram-positive organisms. Prototype Drug Chart 29-1 compares the similarities and differences in the broad-spectrum

PROTOTYPE DRUG CHART 29-1

Amoxicillin and Dicloxacillin

Drug Class
amoxicillin: Broad-spectrum penicillin
dicloxacillin: Penicillinase-resistant penicillin
Trade Names:
amoxicillin: Amoxil
dicloxacillin: Dynapen
Pregnancy Category: B

Dosage
amoxicillin:
A: PO: 250 q8h or 500 mg q12h
C: PO: 20-40 mg/kg/d in 3 divided doses
dicloxacillin:
A: PO: 125-500 mg q6h
C: PO: 12.5-25 mg/kg/d q6h

Contraindications
amoxicillin/dicloxacillin: Allergic to penicillin, asthma, inflammatory bowel disease, pseudomembranous colitis, ulcerative colitis
amoxicillin: mononucleosis
Caution: amoxicillin/dicloxacillin: Hypersensitivity to cephalosporins
amoxicillin: renal impairment

Drug-Lab-Food Interactions
Drug: amoxicillin/dicloxacillin: Increase effect with aspirin, allopurinol, probenecid; increase bleeding with oral anticoagulants; increase effect of methotrexate; decrease effect with tetracycline, erythromycin
Lab: Increase serum AST, ALT, BUN, and creatinine; increase PT, INR
Food: Decrease effect with acidic fruits or juices

Pharmacokinetics
Absorption: PO:
amoxicillin: >80% in GI tract
dicloxacillin: 35%-76% in GI tract
Distribution: PB:
amoxicillin: 20%
dicloxacillin: 95%-99%
Metabolism: t½:
amoxicillin: 1-1.5 h
dicloxacillin: 0.5-1 h
Excretion:
amoxicillin: 70% in urine; clavulanate: 30%-40% in urine
dicloxacillin: Excreted in bile and urine

Pharmacodynamics
amoxicillin:
PO: Onset: 0.5 h
Peak: 1-2 h
Duration: 6-8 h
dicloxacillin:
PO: Onset: 0.5 h
Peak: 1 h
Duration: 4-6 h

Therapeutic Effects/Uses
amoxicillin: To treat respiratory tract infection, urinary tract infection, otitis media, and sinusitis
dicloxacillin: To treat *Staphylococcus aureus* infection
Mode of Action: amoxicillin/dicloxacillin: Inhibition of the enzyme in cell wall synthesis; bactericidal effect

Side Effects
amoxicillin/dicloxacillin: Nausea, vomiting, diarrhea, rash, stomatitis, seizures, pseudomembranous colitis
amoxicillin: Edema, insomnia, dysphagia
dicloxacillin: Abdominal pain, flatulence

Adverse Reactions
amoxicillin/dicloxacillin: Superinfections (vaginitis)
Life-threatening: amoxicillin/dicloxacillin: Blood dyscrasias, thrombocytopenia, neutropenia, hemolytic anemia, bone marrow depression, Stevens-Johnson syndrome
amoxicillin: Respiratory distress
dicloxacillin: Eosinophilia, agranulocytosis, angioedema, liver toxicity

A, Adult; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *BUN,* blood urea nitrogen; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *PB,* protein-binding; *PO,* by mouth; *t ½,* half-life; *>,* greater than.

penicillin amoxicillin and the penicillinase-resistant penicillin dicloxacillin.

Extended-Spectrum Penicillins (Antipseudomonal Penicillins)

The antipseudomonal penicillins are a group of broad-spectrum penicillins. This group of drugs is effective against *Pseudomonas aeruginosa,* a gram-negative bacillus that is difficult to eradicate. These drugs are also useful against many gram-negative organisms such as *Proteus* spp., *Serratia* spp., *Klebsiella pneumoniae, Enterobacter* spp., and *Acinetobacter* spp. The antipseudomonal penicillins are not penicillinase-resistant. Their pharmacologic action is similar to that of aminoglycosides, but they are less toxic.

Table 29-3 lists the drugs in the four categories of penicillin-type antibacterials. The administration route of various types of penicillins (oral, IM, IV), along with the cephalosporins, are available on the Evolve website.

TABLE 29-3 ANTIBACTERIALS: PENICILLINS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Basic Penicillins		
penicillin G procaine (Crysticillin, Wycillin)	A: IM: 600,000-1 million units/d in 1-2 divided doses C: IM: 300,000 units/d in 1-2 divided doses	For moderately serious infections. Slow IM absorption with prolonged action. Solution is milky. Pregnancy category: B; PB: 60%; t½: 0.5-1 h
penicillin G benzathine (Bicillin L-A)	A: IM: 1.2 million units as a single dose C >27 kg: IM: 900,000 units/dose C <27 kg: IM: 300,000-600,000 units/dose	Long-acting penicillin when given by injection. Used as prophylaxis for rheumatic fever. Pregnancy category: B; PB: 60%; t½: 0.5-1 h
penicillin G sodium/ potassium (Pfizerpen)	A: IM/IV: 5-24 million units/d in divided doses q4-6 h; *max:* 80 million units/d C: IM/IV: 150,000-300,000 units/d in divided doses q4-6h; *max:* 24 million units/d Neonates: IM/IV: 50,000- 75,000 units/kg/d in divided doses q6-12h; *max:* 100,000/kg/d	Treatment of lower respiratory infections. Monitor electrolyte levels with high doses. Injectable solution is clear. Pregnancy category: B; PB: 45%-68%; t½: 20-30 min
penicillin V potassium (Veetids)	A/C >12 y: PO: 125-500 mg q6h	Treatment of upper respiratory infections. Acid-stable and less active than penicillin G against some bacteria. Not recommended in renal failure. Take drug after meals. Pregnancy category: B; PB: 75%-89%; t½: 0.5 h
Broad-Spectrum Penicillins		
amoxicillin (Amoxil)	See Prototype Drug Chart 29-1.	
amoxicillin-clavulanate (Augmentin)	A/C >40 kg: PO: 250-500/125 mg q8-12h for 10 d	Treatment of lower respiratory infections, otitis media, sinusitis, skin infections, and UTIs. Pregnancy category: B; PB: 17%-30%; t½: 1-1.5 h
ampicillin (Principen)	A: PO/IM/IV: 250-500 mg q6h C: PO/IM/IV: 25-50 mg/kg/d in 4 divided doses	Treatment of lower respiratory tract infections. First broad-spectrum penicillin. Effective against gram-negative and gram-positive bacteria. Individuals with penicillin allergies may also be allergic to ampicillin. Pregnancy category: B; PB: 15%-28%; t½: 1-1.5 h
ampicillin-sulbactam (Unasyn)	A: IM/IV: 1.5-3 g q6h; *max:* 4 g sulbactam/d C: IV: 100-300 mg/kg/d, in divided doses q6h	Same as ampicillin. Treatment of streptococcus pneumonia, nosocomial pneumonia, skin infections, and *Neisseria gonorrhoeae.* Sulbactam inhibits beta-lactamase thus extending the spectrum. Pregnancy category: B; PB; 28%-38%; t½: 1-2 h
Penicillinase-Resistant Penicillins		
dicloxacillin sodium (Dynapen)	See Prototype Drug Chart 29-1.	
nafcillin (Nallpen)	A: IM/IV: 500 mg-2 g q4-6h; *max:* 12 g/d	Highly effective against penicillin G–resistant *Staphylococcus aureus.* Not recommended orally due to instability in gastric juices. Pregnancy category: B; PB: 70%-90%; t½: 0.5-1.5 h
oxacillin sodium	A/C >40 kg: IM/IV: 250 mg-1 g q4-6h; *max:* 6 g C <40 kg: IM/IV: 50-100 mg/kg/d in divided doses q4-6h; *max:* 6 g/d Neonates: IM/IV: 25 mg/kg/d in divided doses q6h	For penicillin-resistant staphylococci in bone, joint, and skin infections. Pregnancy category: B; PB: 89%-94%; t½: 0.5 h
Extended-Spectrum Penicillins		
carbenicillin indanyl (Geocillin)	A: PO: 382-764 mg q6h	The first penicillin-like drug developed to treat infections caused by *Pseudomonas aeruginosa* and *Proteus* spp. Contains large amounts of sodium. Use with caution when administering to patients with hypertension or heart failure. Pregnancy category: B; PB: 30%-60%; t½: 1 h
piperacillin-tazobactam (Zosyn)	A: IV: 3.375 g, q6h over 30 min, 7-10 d	To treat severe appendicitis, skin infections, pneumonia, and beta-lactamase–producing bacteria. Tazobactam is a beta-lactamase inhibitor. Pregnancy category: B; PB: 30%; t½: 0.7-1.5 h
ticarcillin-clavulanate (Timentin)	A: IV: 3.1 g q6h C >3 mo: IV: 50 mg/kg/d in 4-6 divided doses	Clavulanic acid protects ticarcillin from degradation by beta-lactamase enzymes. Effective for treating septicemia and lower respiratory tract, urinary tract, skin, bone, and joint infections. Pregnancy category: B; PB: 45%-65%; t½: 1 h

A, Adult; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *NB,* newborn; *NSS,* normal saline solution; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *UTI,* urinary tract infection; *y,* year; *>,* greater than; *<,* less than.

Beta-Lactamase Inhibitors

When a broad-spectrum antibiotic (e.g., amoxicillin) is combined with a beta-lactamase (enzyme) inhibitor (e.g., clavulanic acid), the resulting antibiotic (e.g., amoxicillin-clavulanic acid [Augmentin]) inhibits the bacterial beta-lactamases, making the antibiotic effective and extending its antimicrobial effect. There are three beta-lactamase inhibitors: clavulanic acid, sulbactam, and tazobactam. These inhibitors are not given alone but combined with a penicillinase-sensitive penicillin such as amoxicillin, ampicillin, piperacillin, or ticarcillin. The combined drugs currently marketed include the following:

- *Oral use:* amoxicillin-clavulanic acid
- *Parenteral use:* ampicillin-sulbactam (Unasyn), piperacillin-tazobactam (Zosyn), and ticarcillin-clavulanic acid (Timentin)

Pharmacokinetics Amoxicillin is well absorbed from the GI tract, whereas dicloxacillin is only partially absorbed. Protein-binding power differs between the two drugs—amoxicillin is 20% protein-bound and dicloxacillin is highly protein-bound (95%). Drug toxicity may result when other highly protein-bound drugs are used with dicloxacillin. Both drugs have short half-lives. Sixty percent of amoxicillin is excreted in the urine; dicloxacillin is excreted in bile and urine.

Pharmacodynamics Both amoxicillin and dicloxacillin are penicillin derivatives and are bactericidal. These drugs interfere with bacterial cell-wall synthesis, causing cell lysis. Amoxicillin may be produced with or without clavulanic acid, an agent that prevents the breakdown of amoxicillin by decreasing resistance to the antibacterial drug. The addition of clavulanic acid intensifies the effect of amoxicillin. The amoxicillin-clavulanic acid preparation (Augmentin) and amoxicillin trihydrate (Amoxil) have similar pharmacokinetics and pharmacodynamics, as well as similar side effects and adverse reactions. When probenecid is taken with amoxicillin or dicloxacillin, the serum antibacterial levels may be increased. The effects of amoxicillin are decreased when taken with erythromycin and tetracycline. The onset of action, serum peak concentration time, and duration of action for amoxicillin and dicloxacillin are very similar.

Geriatrics

Most beta-lactam antibiotics are excreted via the kidneys. With older adults, assessment of renal function is most important. Serum blood urea nitrogen (BUN) and serum creatinine should be monitored. With a decrease in renal function, the antibiotic dose should be decreased.

Side Effects and Adverse Reactions

Common adverse reactions to penicillin administration are hypersensitivity and **superinfection** (occurrence of a secondary infection when the flora of the body is disturbed) (see Table 29-2). Nausea, vomiting, and diarrhea are common GI disturbances. Rash is an indicator of a mild to moderate allergic reaction. Severe allergic reaction leads to anaphylactic shock. Clinical manifestations of a severe allergic reaction include laryngeal edema, severe bronchoconstriction with stridor, and hypotension. Allergic effects occur in 5% to 10% of persons receiving penicillin compounds; therefore close monitoring during the first dose and subsequent doses of penicillin is essential.

Drug Interactions

The broad-spectrum penicillins—amoxicillin and ampicillin—may decrease the effectiveness of oral contraceptives. Potassium supplements can increase serum potassium levels when taken with potassium penicillin G or V. When penicillin is mixed with an aminoglycoside in IV solution, the actions of both drugs are inactivated.

Cephalosporins

In 1948, a fungus called *Cephalosporium acremonium* was discovered in seawater at a sewer outlet off the coast of Sardinia. This fungus was found to be active against gram-positive and gram-negative bacteria and resistant to beta-lactamase (an enzyme that acts against the beta-lactam structure of penicillin). In the early 1960s, cephalosporins were used with clinical effectiveness. For cephalosporins to be effective against numerous organisms, their molecules were chemically altered, and semisynthetic cephalosporins were produced. Like penicillin, the cephalosporins have a beta-lactam structure and act by inhibiting the bacterial enzyme necessary for cell wall synthesis. Lysis to the cell occurs, and the bacterial cell dies.

First-, Second-, Third-, and Fourth-Generation Cephalosporins

Cephalosporins are a major antibiotic group used in hospitals and in health care offices. These drugs are bactericidal with actions similar to penicillin. For antibacterial activity, the beta-lactam ring of cephalosporins is necessary.

Nursing Process

Patient-Centered Collaborative Care

Antibacterials: Penicillins

Assessment

- Assess for allergy to penicillin or cephalosporins. The patient who is hypersensitive to amoxicillin should not take any type of penicillin products. Severe allergic reaction could occur. A small percentage of patients who are allergic to penicillin could also be allergic to a cephalosporin product.
- Evaluate laboratory results, especially liver enzymes. Report elevated alkaline phosphatase, alanine aminotransferase, or aspartate aminotransferase.
- Record urine output. If amount is inadequate (<30 mL/h or <600 mL/d), drug or drug dosage may need to be changed.

Nursing Diagnoses

- Risk for infection related to invasion of bacteria through surgical incision
- Risk for impaired skin integrity related to rash

- Noncompliance with drug regimen related to decreased finances
- Imbalanced nutrition, less than body requirements, related to nausea and vomiting

Planning

- Patient's infection will be controlled and later eliminated.

Nursing Interventions

- Obtain sample (e.g., swab, blood, sputum) for laboratory culture and antibiotic sensitivity testing of infective organism (also known as C&S) before antibiotic therapy is started.
- Monitor for signs and symptoms of superinfection, especially in patients taking high doses of an antibiotic for a prolonged time. Signs and symptoms include stomatitis (mouth ulcers), genital discharge (vaginitis), and anal or genital itching.
- Examine patient for allergic reaction to the penicillin product, especially after the first and second doses. This may be a mild reaction, such as a rash, or a severe reaction, such as respiratory distress or anaphylaxis.
- Have epinephrine available to counteract a severe allergic reaction.
- Do not mix aminoglycosides with a high-dose or extended-spectrum penicillin G, because this combination may inactivate the aminoglycoside.
- Assess patient for bleeding if high doses of penicillin are being given; a decrease in platelet aggregation (clotting) may result.
- Monitor body temperature and infected area.
- Dilute antibiotic for IV use in an appropriate amount of solution as indicated in the drug pamphlet.

Patient Teaching

General

- Teach patient to take *entire* prescribed penicillin product, such as amoxicillin, until the bottle is empty. If only a portion of the penicillin is taken, drug resistance to that antibacterial agent may develop in the future.
- Advise patient who is allergic to penicillin to wear a medical alert bracelet or necklace and carry a card that indicates the allergy. Patient should notify health care provider of any allergy to penicillin when reporting health history.
- Keep drugs out of reach of small children. Request childproof containers.
- Inform patient to report any side effects or adverse reaction that may occur while taking the drug.
- Encourage patient to increase fluid intake; fluids aid in decreasing the body temperature and in excreting the drug.
- Warn patient or child's parent that chewable tablets must be chewed or crushed before swallowing.
- Advise female patients of childbearing years to use an additional form of birth control while taking penicillins.

Diet

- Advise patient to take medication with food to avoid gastric irritation.

Cultural Considerations

- Recognize that patients and family members from various cultural backgrounds may have alternative practices for alleviating infections. Accept adjunctive alternative methods if not harmful to patient.
- Request a translator to obtain a history of symptoms related to infection and any allergies to antibiotics if patient does not speak English.

Evaluation

- Evaluate effectiveness of antibacterial agent by determining whether infection has ceased and whether any side effects, including superinfection, have occurred.

Four groups of cephalosporins have been developed, identified as *generations.* Each generation is effective against a broader spectrum of bacteria (Table 29-4).

Not all cephalosporins are affected by the beta-lactamases. First-generation cephalosporins are destroyed by beta-lactamases, but not all second-generation cephalosporins are affected by beta-lactamases. Third-generation cephalosporins are resistant to beta-lactamases. Most third- and fourth-generation cephalosporins (e.g., aztreonam, imipenem-cilastatin) are effective in treating sepsis and many strains of gram-negative bacilli. The cephalosporins ceftazidime and cefepime, along with aztreonam and imipenem-cilastatin, are effective against most strains of *Pseudomonas aeruginosa.* Table 29-5 lists the other unclassified beta-lactam antibiotics.

Approximately 10% of persons allergic to penicillin are also allergic to cephalosporins, because both groups of antibacterials have similar molecular structures. If a patient is allergic to penicillin and taking a cephalosporin, the nurse should watch for a possible allergic reaction to the cephalosporin, although the likelihood of a reaction is small.

Only a few cephalosporins are administered orally. These include cephalexin (Keflex), cefadroxil (Duricef), cefaclor (Ceclor), cefuroxime axetil (Ceftin), cefuroxime sodium (Zinacef), cefdinir (Omnicef), and cef-tibuten (Cedax). The rest of the cephalosporins are administered IM and IV. Prototype Drug Chart 29-2 describes the drug data related to ceftriaxone (Rocephin).

Pharmacokinetics Cefazolin is administered IM and IV, and cefaclor is given orally. The protein-binding power of cefazolin is greater than that of cefaclor. The half-life of each drug is short, and the drugs are excreted 60% to 80% unchanged in the urine.

TABLE 29-4 ACTIVITY OF THE FOUR GENERATIONS OF CEPHALOSPORINS

GENERATION	ACTIVITY
First	Effective against gram-positive bacteria (streptococci and most staphylococci). Effective against most gram-negative bacteria (*Escherichia coli* and species of *Klebsiella, Proteus, Salmonella,* and *Shigella*).
Second	Same effectiveness as first generation. Possess a broader spectrum against other gram-negative bacteria *(Haemophilus influenzae, Neisseria gonorrhoeae, Neisseria meningitidis, Enterobacter* spp., and several anaerobic organisms).
Third	Same effectiveness as first and second generations. Also effective against gram-negative bacteria (*Pseudomonas aeruginosa, Serratia* spp., and *Acinetobacter* spp). Less effective against gram-positive bacteria.
Fourth	Similar to third generation. Resistant to most beta-lactamase bacteria. Broader gram-positive coverage than third generation. Effective against *E. coli, Klebsiella, Proteus,* streptococci, certain staphylococci, and *P. aeruginosa.*

TABLE 29-5 OTHER BETA-LACTAM ANTIBIOTICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
aztreonam (Azactam)	Severe infections: A: IM/IV: 1.0-2.0 g q6-8h; *max:* 8 g/d C >9 mo: IV: 30 mg/kg q6-8h; max: 120 mg/kg/d	For treatment of gram-negative infections of the lower respiratory tract, urinary tract, skin, and vagina. Not effective against gram-positive organisms. May be used in combination with other antibiotics. Pregnancy category: B; PB: 56%-60%; t½: 1.7-2.1 h
imipenem-cilastatin (Primaxin)	A/C: IM: 500-750 mg q12h A: IV: 250 mg q6-8h; max 1 g/d C: IV: 15-25 mg/kg q6h	For treatment of septicemia and severe infections of the lower respiratory tract, urinary tract, skin, bones, and joints. Effective against most gram-negative organisms, including *Pseudomonas aeruginosa.* Pregnancy category: C; PB: 20%-40%; t½: 1 h
meropenem (Merrem)	A: IV: 1-2 g q8h C >3 mo: IV: 20-40 mg/kg q8h	A carbapenem antibiotic, similar to cephalosporins. Effective against most strains of gram-negative organisms, including *Pseudomonas aeruginosa,* and effective for complicated appendicitis, peritonitis, meningitis, and soft-tissue infections. Pregnancy category: B; PB: 2%: t½: 1.2 h

A, Adult; *C,* child; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *y,* year; *>,* greater than.

Pharmacodynamics Cefazolin and cefaclor inhibit bacterial cell-wall synthesis and produce a bactericidal action. For IM and IV use of cefazolin, the onset of action is almost immediate, and peak concentration time is 5 to 15 minutes for IV use. The peak concentration time for an oral dose of cefaclor is 30 to 60 minutes.

When probenecid is administered with either of these drugs, urine excretion of cefazolin or cefaclor is decreased, which increases the action of the drug. The effects of cefazolin and cefaclor can be decreased if the drug is given with tetracyclines or erythromycin. These drugs can cause false-positive laboratory results for proteinuria and glucosuria, especially when they are taken in large doses.

Table 29-6 lists the cephalosporins in their designated generation, dosages, and considerations.

Side Effects and Adverse Reactions

The side effects and adverse reactions to cephalosporins include GI disturbances (nausea, vomiting, diarrhea), alteration in blood clotting time (increased bleeding) with administration of large doses, and **nephrotoxicity** (toxicity to the kidney) in individuals with a preexisting renal disorder.

Drug Interactions

Drug interactions can occur with certain cephalosporins and alcohol. For example, alcohol consumption may cause flushing, dizziness, headache, nausea, vomiting, and muscular cramps while taking cefamandole, or cefoperazone. Taking uricosuric drugs concurrently can decrease the excretion of cephalosporins, thereby greatly increasing serum levels. Uricosurics increase the excretion rate of uric acid by inhibiting its reabsorption.

Nursing Process
Patient-Centered Collaborative Care

Antibacterials: Cephalosporins

Assessment

- Assess for allergy to cephalosporins or penicillins. If allergic to one type or class of cephalosporin, patient should not receive any other type of cephalosporin or penicillin.
- Record vital signs and urine output. Report abnormal findings, which may include elevated temperature or decreased urine output.
- Evaluate laboratory results, especially those that indicate renal and liver function (blood urea nitrogen, serum creatinine, aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase, and bilirubin). Report abnormal findings. Use these laboratory results for baseline values.

PROTOTYPE DRUG CHART 29-2

Ceftriaxone

Drug Class

ceftriaxone: third-generation cephalosporin
Trade Name: Rocephin
Pregnancy Category: B

Dosage

ceftriaxone:
A: IM/IV: 1-2/d; *max:* 4 g/d
C: IM/IV: 50-75 mg/kg/d in 2 divided doses; *max:* 100 mg/kg/d

Contraindications

Hypersensitivity to cephalosporins, gallbladder disease, pseudomembranous colitis, bleeding, receiving calcium salts IV
Caution: Hypersensitivity to penicillins; vitamin K deficiency, anticoagulants

Drug-Lab-Food Interactions

Drug: increase nephrotoxicity with loop diuretics, aminoglycosides, calcium salts, vancomycin; increase bleeding with anticoagulants
Lab: May increase AST, ALT, ALP, LDH. May increase PT and INR

Pharmacokinetics

Absorption: IM, IV
Distribution: PB: 85%-95%
Metabolism: t½: 6-9 h
Excretion: Urine

Pharmacodynamics

IM: Onset: UK
Peak: 1.5-4 h
Duration: UK
IV: Onset: immediate
Peak: 30 min
Duration: UK

Therapeutic Effects/Uses

For respiratory, urinary, bone, joint, and skin infections; otitis media; surgical infection prophylaxis, septicemia, gonorrhea, *Klebsiella pneumoniae, E. coli, Streptococcus pneumoniae,* and *S. aureus*
Mode of Action: Inhibition of bacterial cell wall synthesis, causing cell death; bactericidal effect

Side Effects

Anorexia, nausea, vomiting, diarrhea, flatulence, rash, flushing, diaphoresis, dyspepsia, abdominal cramps, fever, pruritus, headaches, dizziness, vertigo, weakness, edema

Adverse Reactions

Superinfections, bleeding, epistaxis, angioedema, palpitations, biliary obstruction, cholelithiasis, jaundice, hematuria
Life-threatening: Seizures, anaphylaxis, agranulocytosis, aplastic anemia, hemolytic anemia, leukopenia, thrombocytopenia, neutropenia, pancytopenia, pseudomembranous colitis, Stevens-Johnson syndrome

A, Adult; *ALP,* alkaline phosphatase; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *BUN,* blood urea nitrogen; *C,* child; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *LDH,* lactic dehydrogenase; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *t ½,* half-life; *UK,* unknown.

TABLE 29-6 ANTIBACTERIALS: CEPHALOSPORINS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
First-Generation		
cefadroxil (Duricef)	A: PO: 1-2 g/d in 1-2 divided doses C: PO: 30 mg/kg/d in 2 divided doses	For urinary tract infections, beta-hemolytic streptococcal infections, and staphylococcal skin infections. Well absorbed by GI tract and not affected by food. Pregnancy category: B; PB: 20%; t½: 1-2 h
cefazolin sodium (Ancef)	A: IM/IV: 250 mg-1 g q6-8h; *max:* 12 g/d C: IM/IV: 25-100 mg/kg/d in 3 divided doses; *max:* 6 g/d	For infections including otitis media, skin, bone, and respiratory or urinary tract. Pregnancy category: B; PB: 85%; t½: 1.5-2.5 h
cephalexin (Keflex)	A: PO: 250-500 mg q6h; *max:* 4 g/d C: PO: 25-100 mg/kg/d in 4 divided doses	First acid-stable cephalosporin sufficiently absorbed from the GI tract. For infections including otitis media, skin, bone, and respiratory or urinary tract. Pregnancy category: B; PB: 5%-15%; t½: 1 h
Second-Generation		
cefaclor (Ceclor, Raniclor)	See Prototype Drug Chart 29-2.	
cefotetan (Cefotan)	A: IM/IV: 500 mg-1 g q12h or 1-2 g q24h; *max:* 6 g/d	Effective against some gram-negative organisms, except *Pseudomonas aeruginosa.* Pregnancy category: B; PB: 75%-90%; t½: 3-4.5 h

TABLE 29-6 ANTIBACTERIALS: CEPHALOSPORINS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
cefoxitin sodium (Mefoxin)	A: IM/IV: 1-2 g q6-8h; *max:* 12 g/d C: IM/IV: 80-100 mg/kg/d in divided doses q6-8h; *max:* 160 mg/kg/d	For severe infections and septicemia. Pregnancy category: B; PB: 65%-95%; t½: 45 min-1 h
cefprozil monohydrate (Cefzil)	A: PO: 250-500 mg/d or q12h × 10 d; *max:* 1 g/d C: PO: 7.5-15 mg/kg q12h × 10 d; *max:* 30 mg/kg/d	Effective against gram-positive bacilli including *Staphylococcus aureus.* With impaired renal function, dose is usually decreased by 50%. Pregnancy category: B; PB: 36%; t½: 1-1.3 h
cefuroxime (Ceftin, Zinacef)	A: PO: 250-500 mg q12h IM/IV: 750 mg-1.5 g q8h C: PO: 125-250 mg q12h IM/IV: 50-100 mg/kg/d in divided doses q6-8h	Similar to cefamandole. Effective in treating meningitis and septicemia and for cardiothoracic procedures and surgical prophylaxis. Pregnancy category: B; PB: 33%-50%; t½: 1.5 h
Third-Generation		
cefdinir (Omnicef)	A/C >43 kg: PO: 300 mg q12h C <43 kg: PO: 7 mg/kg q12h	New third-generation cephalosporin. For otitis media, acute sinusitis, chronic bronchitis, pharyngitis and tonsillitis, pneumonia, and skin infections. Active for *Haemophilus influenzae, Streptococcus pyogenes, Neisseria gonorrhoeae,* and many strains of enteric gram-negative bacilli. Pregnancy category: B; PB: 60%-70%; t½: 1.7 h
cefixime (Suprax)	A/C >50 kg: PO: 400 mg/d in divided doses q12-24h C <50 kg: PO: 8 mg/kg/d in divided doses q12-24h	For UTI, otitis media, and bronchitis. Effective against *Streptococcus pyogenes,* Streptococcus pneumonia, and gram-negative bacilli including *Haemophilus influenzae* and *Neisseria gonorrhoeae.* Pregnancy category: B; PB: 65%-70%; t½: 3-4 h
cefoperazone (Cefobid)	A: IM/IV: 1-2 g q12h	To treat respiratory, urinary tract, and female genital tract infections. Most effective against *Pseudomonas.* Pregnancy category: B; PB: 80%-90%; t½: 2 h
cefotaxime (Claforan)	A/C >50 kg: IM/IV: 1-2 g q8-12h; *max:* 12 g/d C <50 kg: IM/IV: 50-180 mg/kg/d in 4-6 divided doses; *max:* 12 g/d	First of the third generation. Effective against *P. aeruginosa.* Also used in treating gram-negative meningitis. Pregnancy category: B; PB: 13%-38%; t½: 1-2 h
cefpodoxime (Vantin)	A: PO: 200 mg q12h for 10 d C: 6 mo-12 y: PO: 10 mg/kg/d	To treat otitis media and respiratory and urinary tract infections. Food enhances drug absorption. Pregnancy category: B; PB: 22%-33%; t½: 3 h
ceftazidime (Fortaz)	A: IM/IV: 1-2 g q8-12h; *max:* 6 g/d C: IV: 30-50 mg/kg q8h; *max:* 150 mg/kg/d	Most effective against *Pseudomonas spp.* Pregnancy category: B; PB: <10%; t½: 1.5-2 h
ceftriaxone (Rocephin)	See Prototype Drug Chart 29-2.	
ceftizoxime sodium (Cefizox)	A: IM/IV: 500 mg-2 g q8-12h; *max:* 12 g/d C: IV: 50 mg/kg q6-8h; *max:* 200 mg/kg/d	For respiratory, urinary tract, skin, bone, and joint infections. For surgical prophylaxis. Pregnancy category: B; PB: 30%; t½: 1.7 h
ceftibuten (Cedax)	A: PO: 400 mg/d × 10 d C: 6 mo-12 y: PO: 9 mg/kg/d × 10 d; *max:* 400 mg/d	For chronic bronchitis, pharyngitis, and tonsillitis. Active against gram-positive and gram-negative bacteria, *H. influenzae, Streptococcus pneumoniae,* and *Streptococcus pyogenes.* Poor activity against staphylococci and pneumococci. Pregnancy category: B; PB: 65%; t½: 2-2.5 h
cefditoren pivoxil (Spectracef)	A/C: PO: 200-400 mg b.i.d. for 10 d; *max:* 800 mg/d	For chronic bronchitis, pharyngitis, tonsillitis, skin infections, and other mild to moderate bacterial infections. Pregnancy category: B; PB: 88%; t½: 1.6 h
Fourth-Generation		
cefepime (Maxipime)	Mild to moderate infection: A: IV: 0.5-2g q12h; *max:* 6 g/d C: IV: 50 mg/kg q12h; *max:* 50 mg/kg/dose	Similar to third-generation cephalosporins. Resistant to most beta-lactamase bacteria. Effective against pneumonia, *E. coli, Klebsiella, Proteus, streptococci,* certain staphylococci, and *P. aeruginosa.* Has a broader gram-positive coverage than the third-generation cephalosporins. Pregnancy category: B; PB: 16%-19%; t½: 2-2.3 h

A, Adult; *b.i.d.,* two times a day; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscularly; *IV,* intravenously; *max,* maximum; *mo,* month; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown.

Nursing Diagnoses

- Risk for impaired skin integrity related to rash
- Risk for infection related to invasive procedure
- Noncompliance with drug regimen related to lack of knowledge relevant to regimen behavior
- Imbalanced nutrition, less than body requirements, related to nausea and vomiting.

Planning

- Patient's infection will be controlled and later eliminated.

Nursing Interventions

- Culture the infected area before cephalosporin therapy is started. The organism causing the infection can be determined by culture, and the antibiotics the organism is sensitive to are determined by sensitivity (C&S). (Antibiotic therapy may be started before culture result is reported. The antibiotic may need to be changed after C&S test results are received.)

Patient Teaching

General

- Keep drugs out of reach of children. Request childproof containers.
- Tell patient to report signs of superinfection, such as mouth ulcers or discharge from the anal or genital area.
- Advise patient to ingest buttermilk, yogurt, or acidophilus supplement to prevent superinfection of the intestinal flora with long-term use of a cephalosporin.
- Instruct patient to take the complete course of medication, even when symptoms of infection have ceased.
- Infuse all IV cephalosporins over 30 minutes or as ordered to prevent pain and irritation.
- Observe for hypersensitivity reactions.

Side Effects

- Warn patient to report any side effects from use of oral cephalosporin drugs; these may include anorexia, nausea, vomiting, headache, dizziness, itching, and rash.

Diet

- Advise patient to take medication with food if gastric irritation occurs.
- Encourage patient to take an adequate amount of fluids to avoid dehydration from diarrhea.

Cultural Considerations

- Allow adequate time for information processing for patient whose first language is not English. Failing to do so may result in an inaccurate response or no response.
- Provide time for patients to respond to questions, especially when there is a language barrier.
- Speak clearly and slowly, giving time for translation. Obtain an interpreter if necessary.

Evaluation

- Evaluate the effectiveness of the cephalosporin by determining whether the infection has ceased and that no side effects, including superinfection, have occurred.

CRITICAL THINKING CASE STUDY

SA, age 6 years, has otitis media. The health care provider ordered amoxicillin 250 mg every 8 hours. The nurse asks SA's parent if SA is allergic to any drugs, and the parent says that SA is allergic to penicillin.

1. What are the similarities and differences in penicillin and amoxicillin? Explain your answer.
2. What nursing action should the nurse take? Why?

The health care provider changed the amoxicillin order to cefaclor (Ceclor) 250 mg every 8 hours. The therapeutic dosage for children is 20 to 40 mg/kg/d in three divided doses. The child weighs 40 pounds.

3. What are the similarities and differences in amoxicillin and cefaclor? Explain your answer.
4. Is the prescribed cefaclor dosage for SA within safe parameters? Explain your answer.
5. Explain the significance of the nurse asking about allergies to antibiotics such as penicillin. What is the relationship of penicillin and cefaclor in regard to allergies?
6. What should the nurse include in patient teaching for SA and her parents?

NCLEX STUDY QUESTIONS

1. A patient is receiving amoxicillin (Amoxil). The nurse understands that the action of this drug is by which process?
   a. Inhibition of protein synthesis
   b. Alteration of membrane permeability
   c. Inhibition of bacterial cell-wall synthesis
   d. Alteration of bacterial ribonucleic acid synthesis
2. Amoxicillin (Amoxil) is prescribed for a patient who has a respiratory infection. The nurse is teaching the patient about this medication and realizes that more teaching is needed when the patient makes which statement?
   a. "This medication should not be taken with food."
   b. "I will take my entire prescription of medication."
   c. "I should report to the physician any genital itching."
   d. "If I experience any excess bleeding, I will contact the health care provider."
3. A patient is prescribed dicloxacillin (Dynapen). For which adverse effect should the nurse monitor the patient?
   a. Constipation
   b. Renal failure
   c. Hypertension
   d. Hemolytic anemia
4. A patient is taking cefoperazone (Cefobid). The nurse anticipates which appropriate nursing intervention(s) for this medication? (Select all that apply.)
   a. Monitoring renal function studies
   b. Monitoring liver function studies
   c. Infusing IV medication over 30 minutes
   d. Monitoring the patient for mouth ulcers
   e. Advising the patient to take the medication with food
5. A patient has been prescribed amoxicillin (Amoxil). What does the nurse know is true about this medication?
   a. It has a normal adult dose of 2 grams q6h.
   b. It has a common side effect of hypotension.
   c. It has an intramuscular administration route.
   d. It is used to treat respiratory infections.
6. Penicillin G has been prescribed for a patient. Which nursing intervention(s) should the nurse perform for this patient? (Select all that apply.)
   a. Collect culture and sensitivity (C&S) before the first dose.
   b. Monitor the patient for mouth ulcers.
   c. Instruct the patient to limit fluid intake to 1000 mL/day.
   d. Have epinephrine on hand for a potential severe allergic reaction.
   e. No particular interventions are required for this patient.
7. A patient is prescribed cephradine (Velosef). Which actions should the nurse implement? (Select all that apply.)
   a. Report seizures to the health care provider.
   b. Advise the patient to eat yogurt to prevent superinfection.
   c. Monitor the patient for allergic reaction, especially after the first and second dose.
   d. Advise the patient to take medication on an empty stomach, even if GI distress occurs.
   e. Culture the infected area before administering the first dose.

NCLEX Study Questions

OBJECTIVES

- Describe the pharmacokinetics and pharmacodynamics of erythromycin.
- Apply the nursing process for tetracyclines, including patient teaching.
- Summarize the nurse's role in detecting ototoxicity and nephrotoxicity associated with the administration of aminoglycosides.
- Explain the importance for ordering peak and trough concentration levels for aminoglycosides.
- Develop a teaching plan for a patient prescribed a fluoroquinolone (quinolone).
- Contrast the nursing interventions for each of the drug categories: macrolides, tetracyclines, aminoglycosides, and fluoroquinolones.

KEY TERMS

bactericidal, p. 414
bacteriostatic, p. 414
hepatotoxicity, p. 415
nephrotoxicity, p. 419
ototoxicity, p. 418
pathogen, p. 414
photosensitivity, p. 419
superinfection, p. 419

The groups of antibacterials discussed in this chapter include macrolides (erythromycin, clarithromycin, azithromycin, and dirithromycin), lincosamides, glycopeptides, ketolides, tetracyclines, glycylcyclines, aminoglycosides, fluoroquinolones (quinolones), and lipopeptides. The macrolides, lincosamides, and tetracyclines are primarily **bacteriostatic** (inhibit bacterial growth) drugs and may be **bactericidal** (kill bacteria), depending on the drug dose or **pathogen** (microorganism capable of producing disease). Glycopeptides, aminoglycosides, and fluoroquinolones are bactericidal drugs.

MACROLIDES, LINCOSAMIDES, GLYCOPEPTIDES, AND KETOLIDES

These four groups of drugs are discussed together, because they have spectrums of antibiotic effectiveness similar to penicillin, although they differ in structure. Drugs from these groups are used as penicillin substitutes, especially in individuals who are allergic to penicillin. Erythromycin is the drug frequently prescribed if the patient has a hypersensitivity to penicillin.

Macrolides

Macrolides, including azithromycin (Zithromax), clarithromycin (Biaxin), and erythromycin (E-Mycin), are called *broad-spectrum antibiotics*. Erythromycin, the first macrolide, was derived from the funguslike bacteria *Streptomyces erythreus* and was first introduced in the early 1950s. Macrolides bind to the 50S ribosomal subunits and inhibit protein synthesis. At low to moderate drug doses, macrolides have a bacteriostatic effect, and with high drug doses, their effect is bactericidal. Macrolides can be administered orally or intravenously (IV) but not intramuscularly (IM), because it is too painful. Administration of IV macrolides should be infused slowly to avoid unnecessary pain (phlebitis).

Gastric acid destroys erythromycin in the stomach; therefore, acid-resistant salts are added to erythromycin (e.g., ethylsuccinate, stearate, estolate) to decrease dissolution (breakdown in small particles) in the stomach. This allows the drug to be absorbed in the intestine. Normally, food does not hamper the absorption of acid-resistant macrolides. Table 30-1 lists the dosages, uses, and considerations of macrolides.

Macrolides are active against most gram-positive bacteria and moderately active against some gram-negative bacteria. Resistant organisms may emerge during treatment. Macrolides are used to treat mild to moderate infections of the respiratory tract, sinuses, gastrointestinal (GI) tract, skin and soft tissue, and diphtheria, impetigo contagiosa, and sexually transmitted infections (STIs).

Erythromycin is the drug of choice for the treatment of mycoplasmal pneumonia and Legionnaire's disease. Biaxin XL is clarithromycin in a once-a-day extended-release tablet to be taken for 7 days. Azithromycin is frequently prescribed for upper and lower respiratory infections, STIs, and uncomplicated skin infections. Table 30-1 lists the drugs developed from the derivatives of erythromycin. Prototype Drug Chart 30-1 details the pharmacologic behavior of azithromycin.

Pharmacokinetics Clarithromycin and erythromycin are readily absorbed from the GI tract, mainly by the duodenum. Azithromycin is incompletely absorbed from the GI tract, and only 37% reaches systemic circulation. Azithromycin and erythromycin are available IV, but intermittent infusions should be diluted in normal saline (NS) or in 5% dextrose in water (D_5W) to prevent phlebitis or burning sensations at the injection site. Azithromycin 500 mg should be diluted in 250 to 500 mL of fluid, and erythromycin lactobionate 1 g should be diluted in 200 to 1000 mL. Macrolides are excreted in bile, feces, and urine. Because only a small amount is excreted in urine, renal insufficiency is not a contraindication for macrolide use.

Pharmacodynamics Macrolides suppress bacterial protein synthesis. The onset of action of oral preparations of erythromycin is 1 hour, peak concentration time is 4 hours, and duration of action is 6 hours. Newer macrolides have a longer half-life and are administered less frequently. Clarithromycin (Biaxin) is administered twice a day, and Biaxin XL is administered once a day. Azithromycin (Zithromax) has up to a 40- to 68-hour half-life and is prescribed to be taken only once a day for 5 days.

Side Effects and Adverse Reactions

Side effects and adverse reactions to macrolides include GI disturbances such as nausea, vomiting, diarrhea, and abdominal cramping. Conjunctivitis may develop as a side effect of azithromycin. The patient should avoid wearing contact lenses if this occurs. Allergic reactions to erythromycin are rare. **Hepatotoxicity** (liver toxicity) can occur when erythromycin and azithromycin are taken in high doses with other hepatotoxic drugs, such as acetaminophen (high doses), phenothiazines, and sulfonamides. Liver damage is usually reversible when the drug is discontinued. Erythromycin should not be taken with clindamycin or lincomycin because they compete for receptor sites.

Drug Interactions

Macrolides can increase serum levels of theophylline (bronchodilator), carbamazepine (anticonvulsant), and warfarin (anticoagulant). If these drugs are given with macrolides, their drug serum levels should be closely monitored. To avoid severe toxic effects, erythromycin should not be used with other macrolides. Antacids may reduce zithromycin peak levels when taken at the same time.

Extended Macrolide Group

Derivatives of erythromycin have been effective in the treatment of numerous organisms. Like erythromycin, they inhibit protein synthesis. Many of these macrolides have a longer half-life and are administered once a day. The first extended macrolide group developed after the introduction of erythromycin was clarithromycin (Biaxin), which has been effective against many bacterial infections. Clarithromycin is administered twice a day and the XL formulation is given once a day. Another extended macrolide is azithromycin (Zithromax). This drug has a long half-life of up to 40 to 68 hours; therefore it is only prescribed once a day for 5 days.

Elimination of these drugs is via bile and feces. Azithromycin is frequently prescribed for upper and lower respiratory tract infections, STIs, and uncomplicated skin infections.

When erythromycin is given concurrently with verapamil (Calan), diltiazem (Cardizem), clarithromycin (Biaxin), fluconazole (Diflucan), ketoconazole (Nizoral), and itraconazole (Sporanox), erythromycin blood concentration and the risk of sudden cardiac death increase. Table 30-1 lists the drugs developed from the derivatives of erythromycin.

Common side effects of clarithromycin are nausea, diarrhea, and abdominal discomfort. With azithromycin, the side effects of nausea, diarrhea, and abdominal pain are common.

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Macrolides		
azithromycin (Zithromax)	See Prototype Drug Chart 30-1.	
clarithromycin (Biaxin)	A: PO: 250-500 mg q12h × 7-14 d or XL 1 g/d; *max:* 1 g/d C: PO: 7.5 mg/kg b.i.d.; *max:* 15 mg/kg/d	For upper and lower respiratory tract infections, skin and soft-tissue infections, *Helicobacter pylori* and mycobacterial species, and gram-positive and gram-negative organisms. Report persistent diarrhea. Pregnancy category: C; PB: 65%-75%; t½: 3-6 h
erythromycin base (E-Mycin); erythromycin ethylsuccinate (E.E.S., Pediamycin) erythromycin stearate (Erythrocin Stearate)	A: PO: 250-500 mg q6h; *max:* 4 g/d C: PO: 20-50 mg/kg q6h; *max:* 2 g/d	For moderate to severe infections (e.g., pneumococcal pneumonia, acute pelvic inflammatory disease, intestinal amebiasis, Legionnaires' disease, chlamydial infections). Report persistent diarrhea. Pregnancy category: B; PB: 73%-81%; t½: PO: 1-2 h; IV: 3-5 h
erythromycin IV (Erythrocin lactobionate)	A/C/older adults: IV: 15-20 mg/kg/d in 4 divided doses; *max:* 4 g/d	For IV administration. Drug should not be dissolved in solution that contains preservative. Same as erythromycin base.
Fidaxomicin (Dificid)	A: PO: 200 mg b.i.d. for 10 d; *max:* 400 mg/d	For treatment of *Clostridium difficile*–associated diarrhea. May cause GI bleeding, GI obstruction, and elevated liver enzymes. Pregnancy category: B; PB: UK; t½: UK
Lincosamides		
clindamycin HCl (Cleocin) clindamycin palmitate (Cleocin Pediatric) clindamycin phosphate (Cleocin Phosphate)	A: PO: 150-600 mg q6-8h; *max:* 2700 mg/d C: PO: 8-20 mg/kg/d in 3-4 divided doses; *max:* 20 mg/kg/d A: IM/IV: 600-1200 mg/d in divided doses; *max:* 2700 mg/d po, 4800 mg/d IV for severe infections C: IM/IV: 20-40 mg/kg/d in 3-4 divided doses; *max:* 40 mg/kg/d	For serious infections. Available in capsule form. Should be taken with full glass of water. Not affected by food. May cause fatal colitis. Pregnancy category: B; PB: 92%-94%; t½: 2-3 h
lincomycin (Lincocin)	A: IM: 600 mg q12-24h IV: 600 mg-1 g q8-12h; *max:* 8 g/d C: IM: 10 mg/kg q12-24h IV: 10-20 mg/kg/d q8-12h	In most situations, this drug has been replaced by clindamycin. May cause fatal colitis. When IV, dilute in 100 mL of IV fluids. Pregnancy category: B; PB: 72%; t½: 4-6 h
Glycopeptides		
vancomycin HCl (Vancocin)	A: IV: 500 mg q6h or 1 g q12h C: IV: 40 mg/kg/d in 4 divided doses; dilute in IV fluids; infuse over 60-90 min	For *S. aureus*–resistant infections and cardiac surgical prophylaxis in patients with penicillin allergy. Adverse reactions include vascular collapse, ototoxicity, nephrotoxicity, and red neck syndrome. Pregnancy category: B (oral)/C (IV); PB: 55%; t½: 4-8 h
telavancin (Vibativ)	A: IV: 10 mg/kg/d over 60 min for 7-14 d; *max:* 10 mg/kg/d	For treating complicated skin and skin structure infections, as well as MRSA. Adverse reactions include hearing loss, red neck syndrome, and blood dyscrasias. Pregnancy category: C; PB: UK; t½: 4-8 h
Ketolides		
telithromycin (Ketek)	A: PO: 800 mg/d for 7-10 d	For treating community-acquired pneumonia. May cause serious hepatotoxicity and worsen myasthenia gravis. Pregnancy category: C; PB: 60%-70%; t½: 10 h
Lipopeptides		
daptomycin (Cubicin)	A: IV: 4-6 mg/kg/d	To treat complicated skin and skin structure infections. Effective against a broad spectrum of gram-positive bacteria and *S. aureus*–resistant infections. Pregnancy category: B; PB: 92%; t½: 8 h

A, Adult; *C,* child; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *mo,* month; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *UK,* unknown; *y,* year.

PROTOTYPE DRUG CHART 30-1

Azithromycin

Drug Class

Antibacterial macrolide

Trade Names: Zithromax, AzaSite

Pregnancy Category: B

Dosage

A: PO: 250-500 mg/d

IV: 500 mg/d

C >6 mo: PO: 10 mg/kg/d on day 1; then 5 mg/kg/d on days 2-5; *max:* 500 mg/d

Contraindications

Hypersensitivity, bradycardia, hypokalemia, hypomagnesemia

Caution: Hepatic dysfunction, lactation, renal dysfunction

Drug-Lab-Food Interactions

Drug: Increase effect of digoxin, cyclosporine, warfarin; decrease effect of penicillins, clindamycin

Pharmacokinetics

Absorption: PO: 37% absorbed

Distribution: PB: 51%

Metabolism: t½: 68 h

Excretion: In bile and small amount in urine

Pharmacodynamics

PO: Onset: 1 h

Peak: 2.5-5 h

Duration: 24 h

IV: Onset: UK

Peak: UK

Duration: UK

Therapeutic Effects/Uses

To treat gram-positive and some gram-negative organisms; for patients who are allergic to penicillin; to treat upper respiratory tract infections, gonorrhea, and skin infections. AzaSite is given for bacterial conjunctivitis.

Mode of Action: Inhibits the steps of protein synthesis; bacteriostatic or bactericidal effect

Side Effects

Blurred vision, headache, drowsiness, dizziness, fatigue, anorexia, nausea, vomiting, diarrhea, tinnitus, abdominal cramps, pruritus, rash

Adverse Reactions

Superinfections, vaginitis, urticaria, stomatitis; hearing loss, dehydration, angioedema, seizures

Life-threatening: Hepatotoxicity, anaphylaxis, Stevens-Johnson syndrome

A, Adult; *C,* child; *d,* day; *h,* hour; *IV,* intravenous; *PB,* protein-binding; *PO,* by mouth; *t ½,* half-life; *UK,* unknown.

Nursing Process
Patient-Centered Collaborative Care

Antibacterials: Macrolides

Assessment

- Assess vital signs and urine output. Report abnormal findings.
- Check laboratory tests (liver enzyme values) to determine liver function. Order liver enzyme tests periodically for patients taking large doses of azithromycin for a continuous period.
- Obtain a history of drugs patient currently takes. The peak level of azithromycin may be decreased by antacids.

Nursing Diagnoses

- Risk for infection related to invasion of bacteria through broken skin
- Risk for impaired tissue integrity related to azithromycin side effects

Planning

- Patient's infection will be controlled and later eliminated.

Nursing Interventions

- Obtain a sample from infected area and send to laboratory for culture and sensitivity (C&S) test before starting azithromycin therapy. Antibiotic can be initiated after obtaining culture sample.
- Monitor vital signs, urine output, and laboratory values, especially liver enzymes: alkaline phosphatase, alanine aminotransferase, aspartate aminotransferase, and bilirubin.
- Monitor patient for liver damage resulting from prolonged use and high dosage of macrolides such as azithromycin. Signs of liver dysfunction include elevated liver enzyme levels and jaundice.
- Administer oral azithromycin 1 hour before or 2 hours after meals. Give with a full glass of water, *not* fruit juice. Give the drug with food if GI upset occurs. Chewable tablets should be chewed, *not* swallowed whole.
- Dilute in an appropriate amount of solution as indicated in the drug circular for IV azithromycin.
- Administer antacids either 2 hours before or 2 hours after azithromycin.

Patient Teaching

General

- Instruct patient to take full course of antibacterial agent as prescribed. Drug compliance is most important for all antibacterials (antibiotics).

Side Effects

- Encourage patient to report side effects, including adverse reactions (nausea, vomiting, diarrhea, abdominal cramps, itching).
- Teach patient to report any evidence of superinfection. **Superinfection** (a secondary infection resulting from drug therapy) such as stomatitis or vaginitis may occur.
- Tell patient to report onset of loose stools or diarrhea. Pseudomembranous colitis should be ruled out.

Cultural Considerations

- Recognize that patient and family members from various cultural backgrounds may need a written drug schedule as to when the drug should be taken. Have instructions available in the language patient speaks or reads most easily, and emphasize reporting possible side effects to health care provider.

Evaluation

- Evaluate the effectiveness of azithromycin by determining if the infection has been controlled or has ceased and that no side effects, including superinfection, have occurred.

Lincosamides

Like erythromycin, lincosamides inhibit bacterial protein synthesis and have both bacteriostatic and bactericidal actions, depending on drug dosage. Clindamycin (Cleocin) and lincomycin (Lincocin) are examples of lincosamides. Clindamycin is more widely prescribed than lincomycin, because it is active against most gram-positive organisms, including *Staphylococcus aureus* and anaerobic organisms. It is not effective against gram-negative bacteria (e.g., *Escherichia coli, Proteus, Pseudomonas*). Clindamycin is absorbed better than lincomycin through the GI tract and maintains a higher serum drug concentration. Clindamycin is considered more effective than lincomycin and has fewer toxic effects. Table 30-1 lists the lincosamides.

Side Effects and Adverse Reactions

Side effects and adverse reactions to clindamycin and lincomycin include GI irritation, which may manifest as nausea, vomiting, and stomatitis. Rash may also occur. Severe adverse reactions include colitis and anaphylactic shock.

Drug Interactions

Clindamycin and lincomycin are incompatible with aminophylline, phenytoin (Dilantin), barbiturates, and ampicillin.

Glycopeptides

Vancomycin (Vancocin), a glycopeptide bactericidal antibiotic, was widely used in the 1950s to treat staphylococcal infections. Vancomycin is used against drug-resistant *S. aureus* and in cardiac surgical prophylaxis for individuals with penicillin allergies. Serum vancomycin levels should be monitored.

Vancomycin has become ineffective for treating enterococci. Quinupristin/dalfopristin is a combined antibacterial used to treat life-threatening vancomycin-resistant enterococci (VREF) infections. Antibiotic-resistant enterococci can cause staphylococcal endocarditis.

Telavancin (Vibativ), a glycopeptide, treats selected gram-positive bacteria and skin infections. This drug is a semisynthetic derivative of vancomycin, with bactericidal action against MRSA. Telavancin has an advantage of once-daily dosing.

Pharmacokinetics Vancomycin is given orally for treatment of staphylococcal enterocolitis and antibiotic-associated pseudomembranous colitis due to *Clostridium difficile.* When vancomycin is given orally, it is not absorbed systemically and is excreted in the feces. Vancomycin is given IV for severe infections due to MRSA; septicemia; and bone, skin, and lower respiratory tract infections that do not respond or are resistant to other antibiotics. Intermittent vancomycin doses should be diluted in 100 mL for 500 mg and 200 mL for 1 g of D_5W, NS, or LR and administered at a rate of 10 mg/min or a minimum of 60 minutes. Vancomycin is excreted in the urine when given IV. It is 30% protein-bound, and the half-life is 6 hours.

Pharmacodynamics Vancomycin inhibits bacterial cell wall synthesis and is active against several gram-positive microorganisms. The peak action is 30 minutes after the end of the infusion.

Side Effects and Adverse Reactions

Vancomycin may cause nephrotoxicity and ototoxicity. **Ototoxicity** results in damage to the auditory or vestibular branch of cranial nerve VIII. Such damage can result in permanent hearing loss (auditory branch) or temporary or permanent loss of balance (vestibular branch). Side effects may include chills, dizziness, fever, rashes, nausea, vomiting, and thrombophlebitis at the injection site. Too rapid an IV injection of vancomycin can cause a condition known as *"red man" syndrome* or *red neck syndrome.* Characterized by red blotching of the face, neck, and chest, this is a toxic effect rather than an allergic reaction. Other adverse effects include eosinophilia, neutropenia, and Stevens-Johnson syndrome. Severe hypotension, tachycardia, generalized tingling, and, rarely, cardiac arrest are also adverse reactions.

Drug Interactions

Dimenhydrinate (Dramamine) can mask ototoxicity when taken with vancomycin. The risk of nephrotoxicity and ototoxicity may be potentiated when vancomycin is taken with furosemide, aminoglycosides, amphotericin B, colistin, cisplatin, and cyclosporine. Vancomycin may inhibit methotrexate excretion and increase methotrexate toxicity. The absorption of oral vancomycin may be decreased when given with cholestyramine and colestipol.

Ketolides

Ketolides are structurally related to macrolides. The first drug in this class is telithromycin (Ketek), which is used for adults 18 years of age and older to treat mild to moderate community-acquired pneumonia. This disorder is usually caused by *Streptococcus pneumoniae* and *Haemophilus influenza.*

Pharmacokinetics Telithromycin is given orally and is well absorbed by the GI tract and not affected by food intake. Telithromycin is excreted in the feces and urine. It is 60% to 70% protein bound, and the half-life is 10 hours.

Pharmacodynamics Telithromycin inhibits protein synthesis in microorganisms by binding to the bacterial ribosomal RNA site of the 50S subunit, resulting in bacterial cell death. The peak action is 1 hour.

Side Effects and Adverse Reactions

Side effects and adverse reactions to telithromycin include visual disturbances (blurred vision and diplopia), headache, dizziness, altered taste, nausea, vomiting, diarrhea, and liver failure. Telithromycin may also lead to an exacerbation of myasthenia gravis.

Drug Interactions

Telithromycin levels are increased when taken concurrently with antilipidemics (simvastatin, lovastatin, and atorvastatin), itraconazole, ketoconazole, and benzodiazepines. Class 1A or class III antidysrhythmics may lead to life-threatening dysrhythmias. Blood levels of telithromycin are decreased when taken with rifampin, phenytoin, carbamazepine, or phenobarbital, producing a subtherapeutic level. Telithromycin can increase levels of cisapride and pimozide, leading to toxicity; therefore, these two drugs are contraindicated for the patient taking telithromycin. Digoxin, metoprolol, midazolam, ritonavir, sirolimus, and tacrolimus levels are increased when taken concurrently with telithromycin. Concurrent use of telithromycin with ergot alkaloid derivatives leads to ergot toxicity (severe peripheral vasospasm and impaired sensation).

TETRACYCLINES

Tetracyclines, isolated from *Streptomyces aureofaciens* in 1948, were the first broad-spectrum antibiotics effective against gram-positive and gram-negative bacteria and many other organisms—mycobacteria, rickettsiae, spirochetes, and chlamydiae, to name a few. Tetracyclines act by inhibiting bacterial protein synthesis and have a bacteriostatic effect.

Tetracyclines are not effective against *S. aureus* (except for the newer tetracyclines), *Pseudomonas,* or *Proteus.* They can be used against *Mycoplasma pneumoniae.* Tetracycline in combination with metronidazole and bismuth subsalicylate is useful in treating *Helicobacter pylori,* a bacterium in the stomach that can cause a peptic ulcer. For years, oral and topical tetracycline has been used to treat severe acne vulgaris. Low doses are usually prescribed to minimize the toxic effect of the drug.

Continuous use of tetracyclines has resulted in bacterial resistance to the drugs. Tetracycline resistance has increased in the treatment of pneumococcal and gonococcal infections; therefore tetracyclines are not as useful in treating these infections.

The tetracyclines are frequently prescribed for oral use, although they are also available for IM and IV use (Prototype Drug Chart 30-2). Because IM administration of tetracycline causes pain on injection and tissue irritation, this route of administration is seldom used. The IV route is used to treat severe infections. The newer oral preparations of tetracyclines (i.e., doxycycline, minocycline) are more rapidly and completely absorbed. Tetracyclines should not be taken with magnesium and aluminum antacid preparations, milk products containing calcium, or iron-containing drugs, because these substances bind with tetracycline and prevent absorption of the drug. It is suggested that tetracyclines, except for doxycycline and minocycline, be taken on an empty stomach 1 hour before or 2 hours after mealtime. The absorption of doxycycline and minocycline is improved with food ingestion. Table 30-2 describes the tetracycline preparations and their dosages, uses, and considerations. The tetracyclines are listed according to short-acting, intermediate-acting, and long-acting.

Although tetracyclines are widely used, they have numerous side effects, adverse reactions, toxicities, and drug interactions.

Side Effects and Adverse Reactions

GI disturbances such as nausea, vomiting, and diarrhea are side effects of tetracyclines. **Photosensitivity** (sunburn reaction) may occur in persons taking tetracyclines, especially demeclocycline (Declomycin). Pregnant patients should not take tetracycline during the first trimester of pregnancy because of possible teratogenic effects. Women in the last trimester of pregnancy and children younger than 8 years of age should *not* take tetracycline because it irreversibly discolors the permanent teeth. Minocycline (Minocin) can cause damage to the vestibular part of the inner ear, which may result in difficulty maintaining balance. Outdated tetracyclines should always be discarded, because the drug breaks down into a toxic by-product. **Nephrotoxicity** (kidney toxicity) results when tetracycline is given in high doses with other nephrotoxic drugs. Because tetracycline can disrupt the microbial flora of the body, **superinfection** (secondary infection resulting from drug therapy) is another adverse reaction that might result.

Drug Interactions

Antacids (Maalox and others) and iron-containing drugs can prevent absorption of tetracycline from the GI tract. Milk and drugs high in calcium can inhibit tetracycline absorption. To avoid drug interaction, these drugs should be taken at least 2 hours apart from tetracycline. Lipid-soluble tetracyclines (doxycycline and minocycline) are actually better absorbed from the GI tract when taken with milk products and food.

The desired action of oral contraceptives can be lessened when taken with tetracyclines. The activity of penicillins given with a tetracycline can be decreased. Tetracyclines could cause a bacterial resistance to the action of penicillin. Administering tetracycline with an aminoglycoside may increase the risk of nephrotoxicity.

PROTOTYPE DRUG CHART 30-2

Doxycycline

Drug Class
Antibacterial: tetracycline
Trade Names: Vibramycin, Vibra-Tabs
Pregnancy Category: D

Dosage
Systemic infection:
A: PO: 100 mg q12h on day 1, then 100/d
C >8 y & <45 kg: PO: 2.2 mg/kg q12h on day 1, then 2.2 mg/kg/d
A/C >45 kg: IV: 200 mg on day 1, then 100-200 mg/d
C >8 y and <45 kg: 4.4 mg/kg on day 1, then 2.2-4.4 mg/kg/d in 1-2 divided doses

Contraindications
Hypersensitivity, sulfite hypersensitivity, pregnancy, severe hepatic or renal disease
Caution: Renal and hepatic dysfunction, hypokalemia, bradycardia, proton pump inhibitor therapy, breastfeeding

Drug-Lab-Food Interactions
Drug: May increase effects of digoxin and warfarin; decrease doxycycline absorption with sucralfate, antacids, iron, calcium, magnesium, and zinc; decrease effects of oral contraceptives, ciprofloxacin; may alter lithium levels
Lab: Decrease serum potassium level
Food: Dairy products decrease effect

Pharmacokinetics
Absorption: PO: 100% absorbed
Distribution: PB: 23%-93%
Metabolism: t½: 14-24 h
Excretion: Urine and bile

Pharmacodynamics
PO: Onset: 1-2 h
Peak: 2-4 h
Duration: 12 h
IV: Onset: Rapid
Peak: 0.5-1 h
Duration: 12 h

Therapeutic Effects/Uses
To treat infections caused by uncommon gram-positive and gram-negative organisms, respiratory and skin infections or disorders, chlamydial infection, gonorrhea, syphilis, rickettsial infection, and inflammatory papules and pustules associated with rosacea in adults
Mode of Action: Inhibits the steps of protein synthesis; bacteriostatic or bactericidal

Side Effects
Nausea, vomiting, diarrhea, rash, flatulence, abdominal discomfort, headache, photosensitivity, pruritus, heartburn, color vision changes, teeth discoloration

Adverse Reactions
Superinfections, severe photosensitivity, angioedema, hyperglycemia, hypertension
Life-threatening: Blood dyscrasias, hepatotoxicity, intracranial hypertension, pseudomembranous colitis, Stevens-Johnson syndrome

A, Adult; *b.i.d.,* twice a day; *C,* child; *CNS,* central nervous system; *d,* day; *h,* hour; *IV,* intravenous; *PB,* protein binding; *PO,* by mouth; *t½,* half life; *y,* year.

GLYCYLCYCLINES

Tigecycline (Tygacil) is an antibiotic in a category called *glycylcycline*, a synthetic analogue of the tetracyclines. This drug acts by blocking protein synthesis in bacterial cells, resulting in a bacteriostatic action. Indications for use are complicated skin infections and intraabdominal infections, including *Staphylococcus aureus, Escherichia coli, Streptococcus pyogenes, Klebsiella pneumoniae,* and *Clostridium perfringens.*

Pharmacokinetics Tigecycline is administered IV at an initial loading dose of 100 mg over 30 to 60 minutes, followed by 50 mg q12h. The protein-binding capacity of tigecycline ranges from 71% to 89%, and the half-life is 42 hours. The drug is eliminated from the body in bile, feces, and urine, with biliary excretion being the primary route. The pregnancy category is D.

Pharmacodynamics Tigecycline binds to the 30S ribosomal subunit and causes cell death. It has broad-spectrum activity against gram-positive and gram-negative bacterial pathogens.

Side Effects and Adverse Reactions

Because of their related structural formulas, many side effects of tigecycline are similar to those of tetracycline. The most common side effects of tigecycline involve the GI tract and include nausea, vomiting, abdominal pain, and diarrhea. Pseudomembranous colitis may occur but is rare. Other side effects are photosensitivity, headache, dizziness, insomnia, hypertension, hypotension, anemia, leukocytosis, and thrombocythemia. Hyperglycemia, hypokalemia, elevated BUN, and elevated liver enzymes may occur.

Nursing Process

Patient-Centered Collaborative Care

Antibacterials: Tetracyclines

Assessment

- Assess vital signs and urine output. Report abnormal findings.
- Check laboratory results, especially those that indicate renal and liver function (blood urea nitrogen, serum

TABLE 30-2 ANTIBACTERIALS: TETRACYCLINES AND GLYCYLCYCLINES

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Short-Acting Tetracycline		
tetracycline (Sumycin)	A: PO: 250 mg q6h or 500 mg q12h; *max:* 4 g/d C >8y: PO: 25-50 mg/kg/d in 4 divided doses; *max:* 3 g/d	For infections caused by gram-positive and gram-negative microorganisms, respiratory and skin disorders, chlamydial infection, gonorrhea, syphilis, and rickettsial infections. Pregnancy category: D; PB: 65%; t½: 6-12 h
Intermediate-Acting Tetracycline		
demeclocycline HCl (Declomycin)	A: PO: 150 mg q6h or 300 mg q12h C >8 y: PO: 8-12 mg/kg/d in 2-3 divided doses	For gram-positive and gram-negative bacteria. Severe photosensitivity may occur. Pregnancy category: D; PB: 65%-91%; t½: 10-15 h
Long-Acting Tetracyclines		
doxycycline hyclate (Vibramycin)	See Prototype Drug Chart 30-2.	
minocycline HCl (Minocin)	A: PO/IV: Initially: 200 mg; 100 mg q12h C >8 y: PO/IV: Initially: 4 mg/kg/d; 2 mg/kg q12h	For bacterial infections and acne. Should take with food. Pregnancy category: D; PB: 55%-88%; t½: 11-26 h
Glycylcyclines		
tigecycline (Tygacil)	A: IV: Initially: 100 mg; then 50 mg q12h for 5-14 days	For complicated skin and intraabdominal infections. Pregnancy category: D; PB: 71%-89%; t½: 42 h

A, Adult; *C*, child; *d*, day; *h*, hour; *IM*, intramuscular; *IV*, intravenous; *max*, maximum; *PB*, protein-binding; *PO*, by mouth; *t½*, half-life; *UK*, unknown; *y*, year; *>*, greater than.

creatinine, aspartate aminotransferase, alanine aminotransferase, bilirubin).

- Obtain a history of dietary intake and drugs patient currently takes. Dairy products, antacids, iron, calcium, and magnesium decrease drug absorption. Digoxin absorption is increased, which may lead to digitalis toxicity.

Nursing Diagnoses

- Risk for infection related to invasion of bacteria into respiratory tract
- Noncompliance with drug regimen related to denial of illness
- Risk for impaired skin integrity related to adverse effect of tetracycline (sunburn)
- Imbalanced nutrition: less than body requirements, related to nausea and vomiting.

Planning

- Patient's infection will be controlled and later eliminated.

Nursing Interventions

- Obtain a sample for culture from the infected area, and send to laboratory for culture and sensitivity test. Antibiotic therapy can be started after the culture sample has been taken.
- Administer tetracycline 1 hour before or 2 hours after meals for optimum absorption.
- Monitor laboratory values for liver and kidney functions (in particular, liver enzymes, blood urea nitrogen, serum creatinine).
- Record vital signs and urine output.

Patient Teaching

General

- Tell patient to store tetracycline away from light and extreme heat. Tetracycline decomposes in light and heat, causing the drug to become toxic.
- Advise patient to check expiration date on bottle of tetracycline; out-of-date tetracycline can be toxic.
- Inform female patients who are contemplating pregnancy to avoid taking tetracycline because of possible teratogenic effect.
- Warn parents that children younger than 8 years of age should not take tetracycline because it can cause discoloration of permanent teeth.
- Encourage patient to take complete course of tetracycline as prescribed.

Side Effects

- Advise patient to use sun block and protective clothing during sun exposure. Photosensitivity is associated with tetracycline.
- Encourage patient to report signs of a superinfection (mouth ulcers, anal or genital discharge).
- Advise patient to use additional contraceptive techniques and *not* to rely on oral contraceptives when taking the drug, because effectiveness may decrease.
- Teach patient to use effective oral hygiene several times a day to prevent or alleviate mouth ulcers (stomatitis).

Diet

- Educate patient to avoid milk products, iron, and antacids. Tetracycline should be taken 1 hour before or 2 hours after meals with a full glass of water. If GI upset occurs, the drug can be taken with nondairy foods.

Cultural Considerations

- Recognize that patient and family members from various cultural backgrounds may need a written drug schedule as to when the drug should be taken. Explain how dairy products should not be taken with specific tetracyclines, but that food helps with the absorption of minocycline and doxycycline.
- Provide a detailed explanation orally or in written form of the possible side effects that should be reported to the health care provider.

Evaluation

- Evaluate the effectiveness of tetracycline by determining whether the infection has been controlled or has ceased and that there are no side effects.

Drug Interactions

Oral contraceptives may be less effective when given concurrently with tigecycline. Warfarin levels may be increased and may lead to bleeding when taken with tigecycline.

AMINOGLYCOSIDES

Aminoglycosides act by inhibiting bacterial protein synthesis. The aminoglycoside antibiotics are used against gram-negative bacteria such as *E. coli*, *Proteus* spp., and *Pseudomonas* spp. Some gram-positive cocci are resistant to aminoglycosides, so penicillins or cephalosporins may be used.

Streptomycin sulfate, derived from the bacterium *Streptomyces griseus* in 1944, was the first aminoglycoside available for clinical use and was used to treat tuberculosis. Because of its ototoxicity and the bacterial resistance that can develop, it is infrequently used today. Despite its toxicity, streptomycin is the drug of choice to treat tularemia and bubonic pneumonic forms of plague.

Aminoglycosides are for serious infections. Aminoglycosides cannot be absorbed from the GI tract and cannot cross into the cerebrospinal fluid. They cross the blood-brain barrier in children but not in adults. These agents are primarily administered IM and IV, except for a few aminoglycosides (e.g., neomycin, paromomycin) that may be given orally to decrease bacteria and other organisms in the bowel. Neomycin is frequently used as a preoperative bowel antiseptic. Paromomycin is useful in treating intestinal amebiasis and tapeworm infestation.

The aminoglycosides currently used to treat *Pseudomonas aeruginosa* infection include gentamicin, tobramycin, and amikacin. *P. aeruginosa* is sensitive to gentamicin. Amikacin may be used when there is bacterial resistance to gentamicin and tobramycin. Prototype Drug Chart 30-3 lists the drug data related to the aminoglycoside gentamicin.

Pharmacokinetics Gentamicin is administered IM and IV. This drug has a short half-life, and the drug dose can be given three to four times a day. Excretion of this drug is primarily unchanged in the urine.

Pharmacodynamics Gentamicin inhibits bacterial protein synthesis and has a bactericidal effect. Gentamicin has a pregnancy category of C. The onset of action is rapid or immediate. The peak action for gentamicin is 1 to 2 hours.

To ensure a desired blood level, aminoglycosides are usually administered IV. The patient's blood levels are drawn periodically to determine the drug's peak blood level (highest concentration) and trough level (lowest concentration). A therapeutic drug level can be maintained by monitoring the trough level, and peak levels are useful to monitor for toxicity. Many other antibiotics should be monitored as well to maintain effective blood levels.

IV aminoglycosides can be given with penicillins and cephalosporins but should not be mixed together in the same container. When combinations of antibiotics are given IV, the IV line is flushed after each antibiotic has been administered to ensure that the antibiotic was completely delivered.

Side Effects and Adverse Reactions

Serious adverse reactions to aminoglycosides include ototoxicity and nephrotoxicity. Renal function, drug dose, and age are all factors that determine whether a patient will develop nephrotoxicity from aminoglycoside therapy. Careful drug dosing is especially important with younger and older patients. The nurse must assess changes in patients' hearing, balance, and urinary output. Prolonged use of aminoglycosides could result in a superinfection. Specific serum aminoglycoside levels should be closely monitored to avoid adverse reactions. Table 30-3 lists the aminoglycosides and their dosages, uses, and considerations.

Nursing Process

Patient-Centered Collaborative Care

Antibacterials: Aminoglycosides

Assessment

- Record vital signs and urine output. Compare these results with future vital signs and urine output. An adverse reaction to most aminoglycosides is nephrotoxicity.
- Assess laboratory results to determine renal and liver functions, including blood urea nitrogen, serum creatinine, alkaline phosphatase, alanine aminotransferase, aspartate aminotransferase, and bilirubin. Serum electrolytes should also be checked. Aminoglycosides may decrease serum potassium and magnesium levels.
- Obtain a medical history related to renal or hearing disorders. Large doses of aminoglycosides could cause nephrotoxicity or ototoxicity.

Nursing Diagnoses

- Risk for infection related to invasion of bacteria
- Risk for impaired tissue integrity related to aminoglycoside side effect of rash
- Imbalanced nutrition, less than body requirements, related to inability to ingest food
- Risk for ineffective peripheral tissue perfusion: renal related to an aminoglycoside adverse effect of nephrotoxicity

PROTOTYPE DRUG CHART 30-3

Gentamicin Sulfate

Drug Class Antibacterial: aminoglycoside Pregnancy Category: D	**Dosage** A: IM/IV: 3-5 mg/kg/d in 3-4 divided doses C: IM/IV: 2-2.5 mg/kg q8h TDM: Peak: 5-8 mcg/mL; trough: 0.5-2 mcg/mL
Contraindications Hypersensitivity, severe renal disease, pregnancy, and pseudomembranous colitis Caution: Renal disease, neuromuscular disorders (myasthenia gravis, parkinsonism), heart failure, older adults, neonates	**Drug-Lab-Food Interactions** Drug: Increase risk of ototoxicity with loop diuretics, methoxyflurane; increase risk of nephrotoxicity with amphotericin B, polymyxin, cisplatin, furosemide, vancomycin Lab: Increase BUN, serum AST, ALT, LDH, bilirubin, creatinine; decrease serum potassium and magnesium
Pharmacokinetics Absorption: IM, IV Distribution: PB: 0%-30% Metabolism: t½: 2 h Excretion: Unchanged in urine	**Pharmacodynamics** IM/IV: Onset: rapid Peak: 1-2 h Duration: 6-8 h
Therapeutic Effects/Uses To treat serious infections caused by gram-negative organisms (e.g., *Pseudomonas aeruginosa, Proteus*); to treat pelvic inflammatory disease; effective against methicillin-resistant *Staphylococcus aureus* infections Mode of Action: Inhibits bacterial protein synthesis; bactericidal effect	
Side Effects Anorexia, nausea, vomiting, rash, numbness, visual disturbances, headache, confusion, depression, tremors, tinnitus, hearing loss, pruritus, muscle cramps or weakness, photosensitivity, alopecia, arthralgia	**Adverse Reactions** Oliguria, urticaria, palpitations, superinfection, peripheral neuropathy, laryngeal edema, hypokalemia, hypomagnesemia, hyponatremia Life-threatening: Ototoxicity, nephrotoxicity, thrombocytopenia, agranulocytosis, neuromuscular blockade, liver damage

A, Adult; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *BUN,* blood urea nitrogen; *C,* child; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *LDH,* lactic dehydrogenase; *PB,* protein-binding; *t ½,* half-life; *TDM,* therapeutic drug monitoring; *UK,* unknown.

TABLE 30-3 ANTIBACTERIALS: AMINOGLYCOSIDES

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
amikacin sulfate (Amikin)	A: IM/IV: 10-15 mg/kg/d q8-12h; *max:* 15 mg/kg/d C: IM/IV: 7.5-22.5 mg/kg/d in divided doses; *max:* 15 mg/kg/d TDM: Peak: 25-35 mcg/mL; trough: <5 mg/mL	Effective against gram-negative bacteria, including those resistant to other aminoglycosides. Used for respiratory tract, bone, joint, skin, and soft-tissue infections. Monitor for hearing loss, hepatotoxicity, and nephrotoxicity. Pregnancy category: C; PB: 0%-10%; t½: 2-4 h
gentamicin sulfate	See Prototype Drug Chart 30-3.	
kanamycin sulfate (Kantrex)	A/C: IM/IV: 10-15 mg/kg/d in divided doses	Used orally for hepatic coma. Effective against gram-negative bacteria with the exception of *Pseudomonas aeruginosa.* Monitor for hearing loss and nephrotoxicity. Pregnancy category: D; PB: 10%; t½: 2 h
neomycin sulfate (Myciguent, Neo-Fradin)	Bowel prep: A: PO: 1 g q1h for 4 doses; then 1 g q4h for 5 doses Hepatic coma: A: PO: 1-3 g q6h for 5-6 d; *max:* 12 g/d	Decreases bacteria in the bowel and is used as a preoperative bowel antiseptic. Treats skin infections and diarrhea caused by *E. coli.* Pregnancy category: C; PB: 0%-30%; t½: 3 h
streptomycin sulfate (Streptomycin)	A: IM: 1-2 g/d C: IM: 20-40 mg/kg/d TDM: Peak: 40-50 mcg/mL; trough: <10 mcg/mL	For tuberculosis. Ototoxicity is a major problem. Pregnancy category: D; PB: 35%; t½: 2-3 h
tobramycin sulfate (Nebcin)	A: IM/IV: 3-5 mg/kg/d in divided doses C: IM/IV: 2.5 mg/kg/d in divided doses TDM: Peak: 4-8 mcg/mL; trough: 0.5-2 mcg/mL	Very effective against *P. aeruginosa.* Monitor for hearing loss and nephrotoxicity. Fewer toxic effects than other aminoglycosides. Pregnancy category: D; PB: 10%; t½: 2-3 h

A, Adult; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *TDM,* therapeutic drug monitoring; *UK,* unknown; *wk,* week.

Planning

- Patient's infection will be controlled and later eliminated.

Nursing Interventions

- Send sample from infected area to laboratory for culture to determine organism and antibiotic sensitivity before aminoglycoside is started.
- Monitor intake and output. Urine output should be at least 600 mL/d. Immediately report if urine output is decreased. Urinalysis may be ordered daily. Check results for proteinuria, casts, blood cells, or appearance.
- Check for hearing loss. Aminoglycosides can cause ototoxicity.
- Evaluate laboratory results, and compare with baseline values. Report abnormal results.
- Monitor vital signs. Note if body temperature has decreased.
- For IV use, dilute gentamicin in 50 to 200 mL of normal saline solution or 5% dextrose in water (D$_5$W) solution, and administer over 30 to 60 minutes.
- Check that therapeutic drug monitoring has been ordered for peak and trough drug levels. Blood should be drawn 45 to 60 minutes after drug has been administered for peak levels and minutes before next drug dosing for trough levels. Gentamicin peak values should be 5 to 8 mcg/mL, and trough values should be 0.5 to 2 mcg/mL.
- Monitor for signs and symptoms of superinfection: stomatitis (mouth ulcers), genital discharge (vaginitis), and anal or genital itching.

Patient Teaching

General

- Unless fluids are restricted, encourage patient to increase fluid intake.

Side Effects

- Inform patient to report aminoglycoside side effects: nausea, vomiting, tremors, tinnitus, pruritus, and muscle cramps.
- Direct patient to use sun block and protective clothing during sun exposure. Aminoglycosides can cause photosensitivity.

Cultural Considerations

- Do not give directions such as "Take one blue pill" at a specified time. Instead, provide the name and dosage of the medication in the language patient speaks and reads most easily.

Evaluation

- Evaluate the effectiveness of the aminoglycoside by determining whether or not the infection has ceased and no side effects have occurred.

Drug Interactions

When aminoglycosides are administered concurrently with penicillins, the desired effects of aminoglycosides are greatly decreased. Preferably these drugs should be given several hours apart. The drug action of oral anticoagulants such as warfarin (Coumadin) can increase when taken simultaneously with aminoglycoside administration. The risk of ototoxicity increases when ethacrynic acid and aminoglycoside are given.

FLUOROQUINOLONES (QUINOLONES)

The mechanism of action of fluoroquinolones is to interfere with the enzyme DNA gyrase, which is needed to synthesize bacterial deoxyribonucleic acid (DNA). Their antibacterial spectrum includes bactericidal action on both gram-positive and gram-negative organisms. Nalidixic acid (NegGram) and cinoxacin (Cinobac) are the earliest derivatives of the fluoroquinolone group, prescribed primarily for urinary tract infection caused by common gram-negative organisms such as *E. coli.* These two drugs are no longer available on the market in the United States. The fluoroquinolones are effective against some gram-positive organisms, such as *Streptococcus pneumoniae,* and against *Haemophilus influenzae, P. aeruginosa, Salmonella,* and *Shigella.* This group of antibiotics is useful in the treatment of urinary tract, bone, and joint infections; bronchitis; pneumonia; gastroenteritis; and gonorrhea. Table 30-4 lists the various fluoroquinolones.

Ciprofloxacin (Cipro) and norfloxacin (Noroxin) are synthetic antibacterials related to nalidixic acid. These two fluoroquinolones have a broad spectrum of action on gram-positive and gram-negative organisms, including *P. aeruginosa.* Norfloxacin is indicated for urinary tract infections. Ciprofloxacin is approved for use for urinary tract infections; lower respiratory tract infections; and skin, soft-tissue, bone, and joint infections.

The use of fluoroquinolones as urinary antibiotics is discussed in Chapter 34. Prototype Drug Chart 30-4 lists the drug data related to levofloxacin. Levofloxacin's use is not limited to urinary tract infections.

Levofloxacin (Levaquin) is used primarily to treat respiratory problems, such as community-acquired pneumonia, chronic bronchitis, acute sinusitis, urinary tract infections, and uncomplicated skin infections.

Moxifloxacin (Avelox) is available for once-a-day oral and parenteral dosing. This drug is prescribed to treat the same infections other fluoroquinolones are effective against.

Nursing Process
Patient-Centered Collaborative Care

Antibacterials: Fluoroquinolones

Assessment

- Record vital signs and intake and urine output. Compare these results with future vital signs and urine output. Fluid intake should be at least 2000 mL/d.

TABLE 30-4 ANTIBACTERIALS: FLUOROQUINOLONES (QUINOLONES) AND UNCLASSIFIED DRUGS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Fluoroquinolones		
ciprofloxacin HCl (Cipro)	A: PO: 250-500 mg q12h A: IV: 400 mg q12h C: PO: 10-20 mg/kg q12h C: IV: 6-10 mg/kg q8h	For lower respiratory tract, renal, bone, joint, and skin infections. Pregnancy category: C: PB: 20%-40%; t½: 4 h
levofloxacin (Levaquin)	See Prototype Drug Chart 30-4.	
moxifloxacin (Avelox)	A: PO/IV: 400 mg/d for 10 days	For sinusitis, bronchitis, community-acquired pneumonia, and skin infections. It is 4 to 8 times more active than levofloxacin against *Streptococcus pneumoniae.* Side effects similar to other fluoroquinolones. Pregnancy category: C; PB: 30%-50%; t½: 12 h
norfloxacin (Noroxin)	A: PO: 400 mg b.i.d. for 1-3 wk	For acute and chronic UTIs. Most potent drug of fluoroquinolone group. Food may inhibit drug absorption. Pregnancy category: C; PB: 10%-15%; t½: 3-4 h
ofloxacin (Floxin)	A: PO: 200-400 mg q12h for 7-10 days	For respiratory tract infections, UTIs, prostatitis, skin infections. Not to be taken with meals. Superinfection may result. Avoid excessive sunlight. Pregnancy category: C; PB: 32%; t½: 4-8 h
Unclassified Drugs		
chloramphenicol	A/C: IV: 50 mg/kg/d in 4 divided doses NB: 25 mg/kg/d in 4 divided doses	For severe infections. Drug can be toxic; may cause aplastic anemia. Pregnancy category: C; PB: 50%-60%; t½: 4.5 h
quinupristin/dalfopristin (Synercid)	A: IV: 7.5 mg/kg given over 1 h, q8h × 10 days	For vancomycin-resistant *Enterococcus faecium.* Also effective against skin infected by *Staphylococcus aureus* and *Streptococcus pyogenes.* May have thrombophlebitis at infusion site. Pregnancy category: B; PB: UK; t½: 1-3 h

A, Adult; *b.i.d.,* twice a day; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *NB,* newborn; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *UK,* unknown; *UTI,* urinary tract infection; *wk,* week; *y,* year.

- Assess laboratory results to determine renal function: blood urea nitrogen and serum creatinine.
- Obtain a drug and diet history. Antacids and iron preparations decrease absorption of fluoroquinolones such as levofloxacin (Levaquin). Levofloxacin can increase the effects of theophylline and caffeine. Levofloxacin can increase the effects of oral hypoglycemics. When levofloxacin is taken with NSAIDs, CNS reactions including seizures may occur.

Nursing Diagnoses

- Risk for infection related to an invasion of bacteria
- Risk for impaired tissue integrity related to a fluoroquinolone adverse effect of Stevens-Johnson syndrome
- Noncompliance with drug regimen related to lack of understanding of importance of drug regimen

Planning

- Patient's infection will be controlled and later eliminated.

Nursing Interventions

- Obtain specimen from infected site, and send to laboratory for culture and sensitivity before initiating antibacterial drug therapy.
- Monitor intake and output. Urine output should be at least 750 mL/d. Patient should be well hydrated, and fluid intake should be >2000 mL/d to prevent crystalluria. Urine pH should be <6.7.
- Record vital signs. Report abnormal findings.
- Check laboratory results, especially blood urea nitrogen and serum creatinine. Elevated values may indicate renal dysfunction.
- Administer levofloxacin 2 hours before or after antacids and iron products for absorption. Give with a full glass of water. If GI distress occurs, drug may be taken with food.
- For IV levofloxacin, dilute antibiotic in an appropriate amount of solution as indicated in drug circular. Infuse over 60 minutes.
- Check for signs and symptoms of superinfection: stomatitis (mouth ulcers), furry black tongue, anal or genital discharge and itching.
- Monitor serum theophylline levels when taken concurrently. Levofloxacin can increase theophylline levels. Check for symptoms of central nervous system stimulation: nervousness, insomnia, anxiety, and tachycardia.
- Monitor blood sugar. Levofloxacin can increase effects of oral hypoglycemics.

Patient Teaching

General

- Teach patient to drink at least 6 to 8 glasses (8 oz) of fluid daily.
- Encourage patient to avoid caffeinated products.

PROTOTYPE DRUG CHART 30-4

Levofloxacin

Drug Class Antibacterials: quinolone, fluoroquinolone Trade Name: Levaquin Pregnancy Category: C	**Dosage** A: PO: 500-750 mg/d for 7-14 days IV: 500 mg/d infused over 60 min
Contraindications Severe renal disease, hypersensitivity to other quinolones, myasthenia gravis, pregnancy, and breastfeeding Caution: Seizure disorders, renal dysfunction, children <14 y, older adults, theophylline therapy, dehydration, cardiac dysrhythmias	**Drug-Lab-Food Interactions** Drug: Increase effect of oral hypoglycemics and theophylline, caffeine; decrease drug absorption with antacids, iron; may increase warfarin effects Lab: Increase AST, ALT, prolonged bleeding time
Pharmacokinetics Absorption: PO: well absorbed Distribution: PB: 24%-38% Metabolism: $t\frac{1}{2}$: 6-8 h Excretion: Unchanged in urine	**Pharmacodynamics** PO: Onset: 0.5-1 h Peak: 1-2 h Duration: UK
Therapeutic Effects/Uses To treat moderate to severe lower respiratory tract, renal, skin, bone, and joint infections, anthrax, cellulitis, bronchitis, pneumonia, UTI, PID, gonorrhea, *Staphalococcus aureus,* streptococcus Mode of Action: Interferes with the enzyme DNA gyrase, which is needed for bacterial DNA synthesis; bactericidal effect	
Side Effects Nausea, vomiting, diarrhea, abdominal cramps, flatulence, headache, blurred vision, dizziness, fatigue, restlessness, confusion, depression, insomnia, weakness, nightmares, tremors, rash, flushing, tinnitus, photosensitivity, tendonitis, rare possible tendon rupture	**Adverse Reactions** Palpitations, superinfection, edema, blood dyscrasias, anaphylaxis, hyperkalemia, hypotension, angioedema, peripheral neuropathy Life-threatening: Stevens-Johnson syndrome, hepatotoxicity, nephrotoxicity, encephalopathy, seizures, pseudomembranous colitis, dysrhythmias, suicidal ideation

A, Adult; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *DNA,* deoxyribonucleic acid; *h,* hour; *IV,* intravenous; *min,* minute; *PB,* protein binding; *PO,* by mouth; $t\frac{1}{2}$, half-life; *UK,* unknown; *y,* year; <, less than.

Side Effects

- Direct patient to avoid operating hazardous machinery or operating a motor vehicle while taking drug or until drug stability has occurred, because of possible drug-related dizziness.
- Inform patient that photosensitivity is a side effect of most fluoroquinolones. Patient should use sunglasses, sun block, and protective clothing when in the sun.
- Encourage patient to report side effects, such as dizziness, nausea, vomiting, diarrhea, flatulence, abdominal cramps, tinnitus, rash, and very rare tendon rupture. Older adults are more likely to develop side effects.

Cultural Considerations

- Demonstrate an interest in the patient's family and in other personal matters to establish trust among some Hispanic and Appalachian patients.
- Solicit the patient's opinions and advice.

Evaluation

- Evaluate the effectiveness of the fluoroquinolone by determining if the infection has ceased and the body temperature has returned within normal range.

Moxifloxacin is more active than levofloxacin against *S. pneumoniae.* It is also effective against some strains of *S. aureus* and enterococci, but not VREF. The fluoroquinolones are included in Table 30-4.

Pharmacokinetics Levofloxacin (Levaquin) is well absorbed from the GI tract. It has a low protein-binding effect of 50% and a moderately short half-life of 6 to 8 hours. Levofloxacin is excreted unchanged in the urine.

Pharmacodynamics Levofloxacin inhibits bacterial DNA synthesis by inhibiting the enzyme DNA gyrase. The drug has a high tissue distribution. If possible, it should be taken before meals, because food slows the absorption rate. Antacids also decrease absorption rate. Levofloxacin increases the effect of oral hypoglycemics, theophylline, and caffeine.

Levofloxacin has an average onset of action of 0.5 to 1 hour, and the peak concentration time is 1 to 2 hours. The duration of action is unknown.

LIPOPEPTIDES

Daptomycin (Cubicin) is an FDA-approved antibiotic in the category of *lipopeptides*. Daptomycin acts by binding to the bacterial membrane and causing rapid depolarization of its membrane potential, inhibiting protein, DNA, and RNA synthesis. This action results in bacterial cell death.

Indications for daptomycin include complicated skin infections due to gram-positive microorganisms, septicemia due to *Staphylococcus aureus* infections, and infective endocarditis due to MRSA.

Pharmacokinetics Daptomycin is administered IV at a dose of 4 mg/kg/day. Each 500 mg vial of the medication is diluted in 10 mL of NS 0.9% and allowed to stand for 10 minutes. After gentle rotation of vial to ensure dilution, further dilute in 50 to 100 mL of NS and administer over 30 minutes. However, it should *not* be mixed with dextrose-containing diluents. The protein-binding capacity is 92%, with a half-life of 8 hours. Daptomycin is primarily excreted by the kidneys. The pregnancy category is B.

Pharmacodynamics Daptomycin binds to the bacterial membrane and causes cell death. An effective trough concentration of 5.9 mcg/mL is usually achieved by the third dose.

Side Effects and Adverse Reactions

Side effects that may occur when taking daptomycin include hypertension, hypotension, anemia, numbness, tingling, dizziness, insomnia, pain or burning on urination, nausea, vomiting, diarrhea, constipation, and pallor. More serious adverse effects that have occurred with daptomycin are chest pain, hypokalemia, hyperkalemia, hyperglycemia, hypoglycemia, bleeding, rhabdomyolysis, and pleural effusion.

Drug Interactions

When daptomycin is given with HMG-CoA reductase inhibitors, the risk of rhabdomyolysis is increased. Daptomycin toxicity may be increased when given concurrently with tobramycin. Warfarin may lead to increased bleeding when taken with daptomycin.

UNCLASSIFIED ANTIBACTERIAL DRUGS

Several antibacterials, such as chloramphenicol, spectinomycin, and quinupristin/dalfopristin, do not belong to any major drug group. Chloramphenicol (Chloromycetin) was discovered in 1947 and has a bacteriostatic action by inhibiting bacterial protein synthesis. Because of the toxic effects of chloramphenicol, including blood dyscrasias related to bone marrow suppression, it is used only to treat serious infections. It is effective against gram-negative and gram-positive bacteria and many other microorganisms, such as rickettsiae, *Mycoplasma,* and *H. influenzae.*

Quinupristin/dalfopristin (Synercid) is effective for treating vancomycin-resistant *Enterococcus faecium* (VREF) bacteremia and skin infected by *S. aureus* and *S. pyogenes.* It acts by disrupting the protein synthesis of the organism. When administering the drug through a peripheral IV line, pain, edema, and phlebitis may occur.

CRITICAL THINKING CASE STUDY

JN, a 46-year-old woman, has a wound infection. The culture report stated that the infection was caused by *Pseudomonas aeruginosa* and that JN's temperature was 104° F (40° C). Amikacin sulfate (Amikin) is to be administered IV in 100 mL of D_5W over 45 minutes every 8 hours. The dosage is 15 mg/kg/day in three divided doses. JN weighs 165 pounds.

1. What is the drug classification of amikacin? How many milligrams of amikacin should JN receive every 8 hours?
2. What type of IV infusion should be used? What would be the IV flow rate?
3. When would a wound culture be obtained to determine the appropriate antibacterial agent? Explain your answer.
4. What are the similarities of amikacin to other aminoglycosides such as gentamicin? Would one aminoglycoside be preferred over another? Explain your answer.

   The nurse assesses JN for hearing and urinary function before and during amikacin therapy.
5. What should a hearing assessment include?
6. JN's urine output in the last 8 hours was 125 mL. Explain the possible cause for the amount of urine output. What nursing action should be taken?
7. What laboratory tests monitor renal function?
8. The health care provider requests peak and trough serum amikacin levels. When should the blood samples to determine peak serum level and trough serum level be drawn?

NCLEX STUDY QUESTIONS

1. A patient is taking azithromycin (Zithromax). Which nursing interventions would the nurse plan to implement for this patient? (Select all that apply.)
   - a. Monitor periodic liver function tests.
   - b. Dilute with 50 mL of D_5W for IV administration.
   - c. Instruct the patient to report any hearing loss.
   - d. Instruct the patient to report evidence of superinfection.
   - e. Teach the patient to take oral drug 1 hour a.c. or 2 hours p.c.
   - f. Advise the patient to avoid antacids from 2 hours prior to 2 hours after administration.
2. For which serious adverse effect should the nurse closely monitor a patient who is taking lincosamides?
   - a. Seizures
   - b. Ototoxicity
   - c. Hepatotoxicity
   - d. Pseudomembranous colitis
3. The nurse enters a patient's room to find that his heart rate is 120, his blood pressure is 70/50, and he has red blotching of his face and neck. Vancomycin (Vancocin) is running IVPB. The nurse believes that this patient is experiencing a severe adverse effect called "red man syndrome." What action will the nurse take?
   - a. Stop the infusion and call the laboratory.
   - b. Reduce the infusion to 10 mg/min.
   - c. Encourage the patient to drink more oral fluids up to 2 L/day.
   - d. Report onset of Stevens-Johnson syndrome to the health care provider.
4. A patient is receiving tetracycline (Vibramycin). Which advice should the nurse include when teaching this patient about tetracycline?
   - a. Take sunscreen precautions when at the beach.
   - b. Take an antacid with the drug to prevent severe GI distress.
   - c. Obtain frequent hearing tests for early detection of hearing loss.
   - d. Obtain frequent eye checkups for early detection of retinal damage.
5. A patient is taking levofloxacin (Levaquin). What does the nurse know to be true regarding this drug?
   - a. Administered IV only
   - b. May cause hypertension
   - c. Classified as an aminoglycoside
   - d. An adverse effect is dysrhythmia
6. Which instructions will the nurse include when teaching a patient about gentamicin? (Select all that apply.)
   - a. Patient should report any hearing loss.
   - b. Patient should use sunscreen.
   - c. IV gentamicin will be given over 20 minutes.
   - d. Patient will be monitored for mouth ulcers and vaginitis.
   - e. Peak levels will be drawn 30 minutes before IV dose.
   - f. Patient should increase fluid intake.
7. Which nursing intervention(s) should the nurse consider for the patient taking ciprofloxacin (Cipro)? (Select all that apply.)
   - a. Obtain culture before drug administration.
   - b. Tell patient to avoid taking Cipro with antacids.
   - c. Monitor patient for tinnitus.
   - d. Encourage fluids to prevent crystalluria.
   - e. Infuse IV Cipro over 60 minutes.
   - f. Monitor blood glucose, because Cipro can decrease effects of oral hypoglycemic.

OBJECTIVES

- Differentiate between short-acting and intermediate-acting sulfonamides.
- Compare the similarities and differences between the sulfonamides and sulfadiazine.
- Explain the pharmacokinetics of the sulfonamides.
- Apply the nursing process to the patient taking trimethoprim-sulfamethoxazole.

OUTLINE

Sulfonamides
  Trimethoprim and Sulfamethoxazole
  Topical and Ophthalmic Sulfonamides

photosensitivity, p. 430
synergistic effect, p. 431

Sulfonamides are one of the oldest antibacterial agents used to combat infection. When penicillin was initially marketed, the sulfonamide drugs were not widely prescribed, because penicillin was considered the “miracle drug.” However, use of sulfonamides has increased as a result of new sulfonamides and the combination drug of sulfonamide with an antibacterial agent in preparations such as trimethoprim-sulfamethoxazole (Bactrim, Septra).

SULFONAMIDES

Sulfonamides were first isolated from a coal tar derivative compound in the early 1900s and were produced for clinical use against coccal infections in 1935. It was the first group of drugs used against bacteria. Sulfonamides are not classified as an antibiotic, because they were not obtained from biologic substances. The sulfonamides are **bacteriostatic** because they inhibit bacterial synthesis of folic acid, which is essential for bacterial growth. Humans do not synthesize folic acid but acquire it through the diet; therefore, sulfonamides selectively inhibit bacterial growth without affecting normal cells. Folic acid (folate) is required by cells for biosynthesis of ribonucleic acid (RNA), deoxyribonucleic acid (DNA), and proteins.

The clinical usefulness of sulfonamides alone, not in combination, has decreased for several reasons. The availability and effectiveness of penicillin and other antibiotics has increased, and bacterial resistance to some sulfonamides can develop. Sulfonamides may be used as an alternative drug for patients who are allergic to penicillin. They are still used to treat urinary tract and ear infections and may be used for newborn eye prophylaxis. Sulfonamides are approximately 90% effective against *Escherichia coli;* therefore they are frequently a preferred treatment for urinary tract infections, which are often caused by *E. coli.* They are also useful in the treatment of meningococcal meningitis and against the organisms *Chlamydia* and *Toxoplasma gondii*. Sulfonamides are not effective against viruses and fungi.

Pharmacokinetics Sulfonamide drugs are well absorbed by the gastrointestinal (GI) tract and are well distributed to body tissues and the brain. The liver metabolizes the sulfonamide drug, and the kidneys excrete it.

Pharmacodynamics Many sulfonamides are for oral administration, because they are absorbed readily by the GI tract. They are also available in solution and ointment for ophthalmic use and in cream form (silver sulfadiazine [Silvadene] and mafenide acetate [Sulfamylon]) for burns. Most of the early sulfonamides were highly protein-bound and displaced other drugs by competing for protein sites. The following are two categories of sulfonamides, classified according to their duration of action: (1) short-acting sulfonamides (rapid absorption and excretion rate) and (2) intermediate-acting sulfonamides (moderate to slow absorption and slow excretion rate).

Sulfadiazine is useful in prophylactic treatment of streptococcal infections in patients with rheumatic fever who are hypersensitive to penicillin. Sulfadiazine is poorly soluble in urine and can cause crystallization, which could damage the kidneys if there is insufficient fluid and water intake. Table 31-1 lists the protein-binding, half-life, and solubility in urine of most drugs in the sulfonamide group.

TABLE 31-1 PHARMACOKINETICS OF SELECTED SULFONAMIDES

DRUG	PROTEIN-BINDING (%)	HALF-LIFE (HOURS)	SOLUBILITY IN URINE
Short-Acting			
sulfadiazine (Microsulfon)	20-60	17	+1
Intermediate-Acting			
sulfasalazine (Azulfidine)	99	5-10	+1
trimethoprim-sulfamethoxazole (Bactrim)	50-65	8-12	+1-2

Older sulfonamides (e.g., sulfadiazine) have low solubility and may cause crystallization in the urine. The current sulfonamides have greater water solubility; therefore, crystal formations in the urine and renal damage are unlikely. Table 31-2 describes the sulfonamides.

Side Effects and Adverse Reactions

Side effects of sulfonamides may include an allergic response such as skin rash and itching. Anaphylaxis is not common. Blood disorders such as hemolytic anemia, aplastic anemia, and low white blood cell and platelet counts could result from prolonged use and high dosages. GI disturbances (anorexia, nausea, vomiting) may also occur. The early sulfonamides were insoluble in acid urine, and **crystalluria** (crystals in urine) and hematuria were common problems. Increasing fluid intake dilutes the drug, helping prevent crystalluria from occurring. **Photosensitivity** (excessive reaction to direct sunlight or ultraviolet light leading to redness and burning of skin) can occur, so the patient should avoid sunbathing and excess ultraviolet light. **Cross-sensitivity** (a sensitivity or allergy to one sulfonamide may lead to sensitivity to another sulfonamide) might occur with the different sulfonamides but does not occur with other antibacterial drugs. Sulfonamides should be avoided during the third trimester of pregnancy.

SAFETY: Preventing Medication Errors

Do not confuse…

- **Septra** (an antibacterial-sulfonamide) with **Sectral** (a beta-adrenergic antagonist that is used to manage dysrhythmias).
- **Sulfadiazine** (a short-acting antibacterial-sulfonamide) with **sulfasalazine** (an intermediate acting antibacterial-sulfonamide)

Trimethoprim and Sulfamethoxazole

Trimethoprim is an antibacterial agent that interferes with bacterial folic acid synthesis just as sulfonamides do.

TABLE 31-2 ANTIBACTERIALS: SULFONAMIDES

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Short-Acting		
sulfadiazine (Microsulfon)	A: PO: LD: 2-4 g; then 2-4 g/d in 4-6 divided doses C >2 mo: PO: LD: 75 mg/kg; then 150 mg/kg/d in 4-6 divided doses; *max:* 6 g/d	For systemic infections. Could be classified as a short- to immediate-acting sulfonamide. When taking this drug, increase fluid intake to >2000 mL/d. Pregnancy category: C; PB: 38%-48%; t½: 17 h
Intermediate-Acting		
sulfasalazine (Azulfidine)	A: PO: Initially: 1 g q6-8h; *maint:* 500 mg q6h C >6 y: PO: Initially: 40-60 mg/kg/d in 4-6 divided doses; *maint:* 30 mg/kg/d in 4 divided doses; *max:* 2 g/d	For ulcerative colitis, Crohn's disease, rheumatoid arthritis (some cases), and reduces *Clostridium* and *E. coli* in stools. Take after eating. Side effects include nausea, vomiting, bloody diarrhea. Pregnancy category: B (near term: D); PB: 99%; t½: 6 h
trimethoprim-sulfamethoxazole (Bactrim, Septra)	See Prototype Drug Chart 31-1.	

A, Adult; *C,* child; *d,* day; *h,* hour; *LD,* loading dose; *maint,* maintenance; *max,* maximum; *mo,* month; *PB,* protein-binding; *PO,* by mouth; *t½,* half- life; *y,* year; >, greater than; ≥, greater than or equal to.

Trimethoprim is classified as a urinary tract antiinfective that may be used alone for uncomplicated urinary tract infections. This drug is effective against the gram-negative bacteria *Proteus* spp., *Klebsiella* spp., and *E. coli.* In the 1970s it was combined with the sulfonamide sulfamethoxazole (an intermediate-acting sulfonamide) to prevent bacterial resistance to sulfonamide drugs and to obtain a better response against many organisms. Giving both drugs together in one compound form causes bacterial resistance to develop much more slowly than if only one of the drugs is used alone. This combination drug, trimethoprim-sulfamethoxazole (TMP-SMZ [Bactrim, Septra]) is commonly used. The drug ratio is one part trimethoprim to five parts sulfamethoxazole (1:5). The two drugs have a **synergistic effect,** increasing the desired drug response.

TMP-SMZ is effective in treating urinary, intestinal, and lower respiratory tract infections; otitis media; prostatitis; and gonorrhea. It is also used to prevent *Pneumocystis carinii* in patients with acquired immunodeficiency syndrome (AIDS). Increased fluid intake is highly recommended to avoid complications such as crystallization in the urine. Prototype Drug Chart 31-1 describes the pharmacologic behavior of TMP-SMZ.

Pharmacokinetics TMP-SMZ is well absorbed from the GI tract and is moderately protein-bound. Its half-life is 8 to 12 hours; thus it is administered twice a day. It is excreted as unchanged metabolites in the urine.

Pharmacodynamics TMP-SMZ is known generically as *co-trimoxazole* in many countries. Trimethoprim, a nonsulfonamide antibiotic, enhances the activity of the drug combination. TMP-SMZ blocks steps in bacterial synthesis of protein and nucleic acid, producing a bactericidal effect.

TMP-SMZ can be administered orally or intravenously (IV). Orally the drug has a moderately rapid onset of action; drug action is immediate via the IV route. Serum peak concentration time for oral use is 2 to 4 hours and 0.5 to 1 hour for IV use. TMP-SMZ increases the hypoglycemic response when taken with sulfonylureas (oral hypoglycemic agents). It can also increase the activity of oral anticoagulants.

Side Effects and Adverse Reactions

Side effects of TMP-SMZ may include mild to moderate rashes, anorexia, nausea, vomiting and diarrhea, stomatitis, crystalluria, and photosensitivity. Serious adverse reactions are rare; however, agranulocytosis, aplastic anemia, and allergic myocarditis have been reported as possible life-threatening conditions.

PROTOTYPE DRUG CHART 31-1

Trimethoprim-Sulfamethoxazole (TMP-SMZ)

Drug Class Antibacterial: sulfonamide Trade Names: Bactrim, Septra Pregnancy Category: C (D near term)	**Dosage** A: PO: 160 mg TMP/800 mg SMZ q12-24h A/C: IV: 8-10 mg/kg/d in 2-4 divided doses; infuse over 1-1.5 h C <40 kg: PO: 8/40 mg/kg/d in 2 divided doses
Contraindications Severe renal or hepatic disease, hypersensitivity to sulfonamides, megaloblastic or folate-deficiency anemia, pregnancy, breastfeeding, infants Caution: Malnutrition, hypothyroidism, older adults	**Drug-Lab-Food Interactions** Drug: Increase anticoagulant effect with warfarin; increase hypoglycemic effect with an oral hypoglycemic drug, increase potassium with ACE inhibitors and potassium-sparing diuretics, increase digoxin levels, increase phenytoin and methotrexate toxicity Lab: May increase BUN, serum creatinine, AST, ALT, ALP
Pharmacokinetics Absorption: PO: Well absorbed Distribution: PB: 44% for TMP; 70% for SMZ; crosses placenta Metabolism: t½: 8-10 h for TMP; 6-12 h for SMZ Excretion: In urine as metabolites	**Pharmacodynamics** PO: Onset: 0.5-1 h Peak: 1-4 h Duration: UK IV: Onset: Immediate Peak: 0.5-1 h Duration: UK
Therapeutic Effects/Uses To treat urinary tract infection, otitis media, bronchitis, *Streptococcus pneumoniae, Pneumocystis carinii, Klebsiella, Escherichia coli,* cystitis Mode of Action: Inhibits folic acid synthesis and protein synthesis of nucleic acids; bactericidal effect	
Side Effects Anorexia, nausea, vomiting, diarrhea, abdominal pain, rash, stomatitis, fatigue, depression, headache, vertigo, insomnia, photosensitivity	**Adverse Reactions** Life-threatening: Seizures, leukopenia, thrombocytopenia, increased bone marrow depression, hemolytic anemia, aplastic anemia, agranulocytosis, angioedema, hyperkalemia, hyponatremia, hypoglycemia, crystalluria, pseudomembranous colitis, Stevens-Johnson syndrome, renal failure

A, Adult; *AIDS,* acquired immunodeficiency syndrome; *ALP,* alkaline phosphatase; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *BUN,* blood urea nitrogen; *C,* child; *d,* day; *h,* hour; *IV,* intravenous; *PB,* protein-binding; *PO,* by mouth; *SMZ,* sulfamethoxazole; *TMP,* trimethoprim; *t½,* half-life; *UK,* unknown; >, greater than; <, less than.

Topical and Ophthalmic Sulfonamides

Sulfonamides can be administered for topical and ophthalmic uses, but because topical use of sulfonamides can cause hypersensitivity reactions, they are not frequently used. Mafenide acetate (Sulfamylon) is a sulfonamide derivative prescribed to prevent sepsis in cases of second- and third-degree burns. Silver sulfadiazine (Silvadene) is another topical sulfonamide used to treat burns. Both of these drugs are discussed in more detail in Chapter 50.

Nursing Process
Patient-Centered Collaborative Care

Antibacterials: Sulfonamides

Assessment

- Assess patient's renal function by checking urinary output (>600 mL/d), blood urea nitrogen (normal, 8 to 25 mg/dL), and serum creatinine (normal, 0.5 to 1.5 mg/dL).
- Obtain a medical history from patient. Sulfonamides such as co-trimoxazole (trimethoprim-sulfamethoxazole [Bactrim, Septra]) are contraindicated for patients with severe renal or liver disease.
- Determine if patient is hypersensitive to sulfonamides. An allergic reaction can include rash, skin eruptions, and itching. A severe hypersensitivity reaction includes **erythema multiforme** (erythematous macular, papular, or vesicular eruption; if severe, can cover the entire body) or **exfoliative dermatitis** (desquamation, scaling, and itching of skin).
- Obtain a history of drugs patient currently takes. Oral antidiabetic drugs (sulfonylureas) with sulfonamides increase hypoglycemic effect; use of warfarin with sulfonamides increases anticoagulant effect.
- Assess baseline laboratory results, especially complete blood count (CBC). Blood dyscrasias may occur as a result of high doses of sulfonamides over a continuous period, causing life-threatening conditions.

Nursing Diagnoses

- Risk for infection related to indwelling catheter
- Ineffective protection as evidenced by photosensitivity related to sulfonamides
- Impaired urinary elimination related to prolonged high doses of sulfonamides

Planning

- Patient's infection will be controlled and later alleviated.

Nursing Interventions

- Administer sulfonamides with a full glass of water. Extra fluid intake can prevent crystalluria and kidney stone formation.
- Record patient's intake and output. Urine output should be at least 1200 mL/d to decrease the risk of crystalluria. The sulfonamide sulfadiazine is more likely to cause crystalluria than combination drugs. Fluid intake should be at least 2000 mL/d.
- Monitor vital signs. Note if patient's temperature has decreased.
- Observe patient for hematologic reaction that may lead to life-threatening anemias. Early signs are sore throat, purpura, and decreasing white blood cell and platelet counts. Check patient's CBC, and compare with baseline findings.
- Check for signs and symptoms of superinfection (secondary infection caused by a different organism than the primary infection). Symptoms include stomatitis (mouth ulcers), furry black tongue, anal or genital discharge, and itching.

Patient Teaching

General

- Encourage patient to drink several quarts of fluid daily while taking sulfonamides to avoid the complication of crystalluria.
- Advise pregnant patients to avoid sulfonamides during the last 3 months of pregnancy.
- Inform patient not to take antacids with sulfonamides, because antacids decrease the absorption rate.
- Warn patient who has an allergy to one sulfonamide that all sulfonamide preparations should be avoided, with health care provider's approval, because of the possibility of cross-sensitivity. Observe patient for rash or any skin eruptions.

Self-Administration

- Teach patient to take the sulfonamide 1 hour before or 2 hours after meals with a full glass of water.

Side Effects

- Direct patient to report bruising or bleeding that could be a result of drug-induced blood disorder. Advise patient to have blood cell count monitored on a regular basis.
- Warn patient to wear sunglasses, avoid direct sunlight, and use sun block and protective clothing to decrease the risk of photosensitive reactions.

Cultural Considerations

- Respect cultural beliefs and values regarding alternative methods for treating infections. Explain the purpose of the drug therapy and how often the drug should be taken.
- Communicate that patient should increase fluid intake to 10 to 12 glasses per day. Written instructions in patient's own language may be necessary if patient's cultural background prevents understanding of the health problem and drug regimen.

Evaluation

- Evaluate effectiveness of sulfonamide by determining if infection has been alleviated and if blood cell count is within normal range.

Sulfacetamide sodium (AK-Sulf, Cetamide, Sodium Sulamyd, Sulf-10) is a sulfonamide for ophthalmic and topical uses. In ophthalmic preparations (liquid/drop and ointment), sulfacetamide sodium is used to treat conjunctivitis and corneal ulcers. It is often used as prophylactic treatment after an eye injury or the removal of a foreign body. Note: Do not use ointment for the eye unless it has "ophthalmic" printed on the drug label. Sulfacetamide sodium is discussed in more detail in Chapter 49.

Topical sulfacetamide sodium for the skin is an ointment and is used to treat seborrheic dermatitis and secondary bacterial skin infections. This dermatologic form is not used for the eye.

Information on Bactrim (trimethoprim-sulfamethoxazole [TMP/SMZ]): *www.healthsquare.com/newrx/bac1046.htm*

CRITICAL THINKING CASE STUDY

RM, a 46-year-old woman, has a severe urinary tract infection (UTI). She takes trimethoprim-sulfamethoxazole (Bactrim), 160 mg/800 mg every 6 hours.

1. Is the dose within the recommended drug dose and dosing interval? What is the nurse's responsibility?
2. What are the similarities and differences between trimethoprim-sulfamethoxazole (Bactrim) and sulfadiazine?
3. What are the signs of thrombocytopenia, hemolytic anemia, and agranulocytosis for patients who take high doses of sulfonamides? Explain the assessment and nursing interventions regarding these severe adverse reactions to sulfonamides.

Patient teaching is an important part of nursing interventions. Explain the nurse's role regarding patient teaching concerning the following:

4. What is the required amount of daily fluid intake?
5. What are the cross-sensitive effects if a patient is allergic to other sulfonamide preparations? What allergic reactions may occur?
6. What time of day should sulfonamides be taken?
7. Why should bruising and bleeding be reported?
8. What protective measures should be taken to prevent a possible photosensitive reaction? RM takes the anticoagulant Coumadin, 7.5 mg/day.
9. What effect does Bactrim have on warfarin (Coumadin), and what is the nurse's responsibility? Should RM's Coumadin dosage be increased or decreased? Explain your answer.

NCLEX STUDY QUESTIONS

1. Sulfasalazine (Azulfidine) has been ordered for a patient. The nurse knows that this drug is most effective against which organisms?
   a. *Escherichia coli* and *Clostridium*
   b. *Neisseria gonorrhoeae* and *H. Influenzae*
   c. *Pseudomonas aeruginosa* and *Helicobacter pylori*
   d. *Enterococcus faecium* and *Staphylococcus aureus*
2. A patient is taking sulfasalazine (Azulfidine). What should the nurse teach the patient to do?
   a. Drink at least 10 glasses of fluid per day.
   b. Monitor blood glucose carefully to avoid hyperglycemia.
   c. Avoid operating a motor vehicle because this drug may cause drowsiness.
   d. Take this drug with an antacid to decrease the risk of gastrointestinal distress.

3. The nurse is teaching a patient about sulfadiazine (Microsulfon). Which instructions will the nurse include in the teaching?
   - **a.** Avoid caffeine during sulfonamide treatment.
   - **b.** Administer in 50 mL of fluid over 30 minutes.
   - **c.** Avoid sulfonamides during the third trimester of pregnancy.
   - **d.** Use an ultraviolet light to enhance drug effectiveness.
4. A patient is ordered to take trimethoprim-sulfamethoxazole (Bactrim). The nurse knows to be aware of which adverse effect?
   - **a.** Bronchospasm
   - **b.** Dysrhythmias
   - **c.** Pseudomembranous colitis
   - **d.** Stevens-Johnson syndrome
5. A patient is taking a sulfonamide for an acute urinary tract infection. Which medication does the nurse realize is a short-acting sulfonamide?
   - **a.** sulfasalazine (Azulfidine)
   - **b.** sulfadiazine (Microsulfon)
   - **c.** sulfamethoxazole (Gantanol)
   - **d.** co-trimoxazole/TMP-SMZ (Bactrim)
6. The nurse is teaching a patient about trimethoprim-sulfamethoxazole (Bactrim). Which instructions will the nurse plan to include? (Select all that apply.)
   - **a.** Report any bruising or bleeding.
   - **b.** Report any diarrhea or bloody stools.
   - **c.** Report any fever, rash, or sore throat.
   - **d.** Avoid unprotected exposure to sunlight.
   - **e.** Report thirst and polyuria.

Answers: 1, a; 2, a; 3, c; 4, d; 5, b; 6, a, b, c, d.

UNIT X

Additional Antiinfective Agents

Unit 10 discusses agents prescribed to combat disease-producing microorganisms. Included in this unit are antitubercular, antifungal, antiviral, antimalarial, and anthelmintic drugs. Urinary antiseptics and other drugs for urinary tract disorders are also presented.

Disease-producing organisms may be gram-positive or gram-negative bacteria, viruses, or fungi. The degree to which they are pathogenic depends on the microorganism and its virulence.

Viruses are very small organisms that do not have an organized cellular structure. There are numerous families of virus, including herpesviruses, cytomegalovirus, adenovirus, and papovavirus.

The fungi are divided into yeasts and molds. The few fungi that produce disease usually affect the skin and subcutaneous tissues in conditions such as athlete's foot and ringworm. Serious fungal infections are systemic and usually need aggressive drug therapy. Opportunistic fungal infections commonly result from prolonged antibiotic and steroidal therapies and debilitating diseases such as cancer. The yeast *Candida albicans* is a cause of common infections of the mucous membranes of the mouth, gastrointestinal tract, vagina, and skin. *Candida,* like most fungi, is resistant to penicillin-type antibiotics because of its rigid cell wall structure.

Chapter 32 describes the variety of topical and systemic drugs used to treat yeast and mold infections. Chapter 33 discusses antivirals, antimalarials, and anthelmintics, and Chapter 34 addresses drugs for urinary tract disorders.

- Key Points
- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Compare first-line and second-line antitubercular drugs, and give examples of each.
- Differentiate between the five groups of antifungal drugs.
- Explain the uses of polyenes.
- Differentiate the adverse reactions of antitubercular, antifungal, and peptide drugs.
- Apply the nursing process for patients taking antitubercular, antifungal, and peptide drugs.
- Describe the side effects/adverse effects for metronidazole.

This chapter covers antitubercular drugs, antifungal drugs, peptide drugs, and metronidazole. Although these drug categories differ from each other, they each contain drugs that inhibit or kill organisms that cause disease.

TUBERCULOSIS

Tuberculosis (TB) is caused by the acid-fast bacillus *Mycobacterium tuberculosis.* This pathogen is frequently called the *tubercle bacillus.* Tuberculosis is one of the world's major health problems, killing more persons than any other infectious disease, including **acquired immunodeficiency syndrome** (AIDS) (immune disorder characterized by opportunistic diseases). More than 1.5 billion people in the world have TB, and many are unaware of their infection. Each year more than 8 million new cases of TB are diagnosed. Until the 1980s, the incidence of TB had decreased in the United States. The later increase in TB can be attributed, in part, to the increase in people with AIDS in whom active TB has developed because of compromised immune systems. In addition, the increased incidence is partly a result of increasingly crowded living conditions in urban areas. Patients more susceptible to TB are those with alcohol addiction, AIDS, and debilitative conditions.

Pathophysiology

TB is transmitted from one person to another by droplets dispersed in the air through coughing and sneezing. The organisms are inhaled into the alveoli (air sacs) of the lung. If the body's immune system is strong and intact, phagocytes stop the multiplication of the tubercle bacilli. When the immune system is compromised, however, tubercle bacilli can spread from the lungs to other organs of the body via the blood and lymphatic system. Dissemination of TB bacilli can be found in the liver, kidneys, spleen, and other organs. Symptoms of TB include anorexia, cough and sputum production, increased fever, night sweats, weight loss, and positive acid-fast bacilli in the sputum.

ANTITUBERCULAR DRUGS

Before 1944, many people died from TB because of the absence of drug therapy. Streptomycin, a parenteral antibiotic, was the first drug used to treat TB. Isoniazid (INH), discovered in 1952, was the first oral drug preparation effective against the tubercle bacillus. Isoniazid is a bactericidal drug that inhibits tubercle cell wall synthesis and blocks pyridoxine (vitamin B_6), which is used for intracellular enzyme production. When isoniazid is prescribed, pyridoxine may also be prescribed to avoid deficiency and possible occurrence of peripheral neuropathy. Group names for drugs used to treat TB include *antimycobacterial agents* and **antitubercular drugs** (agents that treat tuberculosis).

Prophylactic antitubercular therapy is suggested for individuals who have been in close contact with persons with TB. Prophylaxis is also recommended for those who test positive for **human immunodeficiency virus** (HIV) (virus causing an infection characterized by profound immunosuppression) and also have a positive TB skin test or are in close contact with someone who has TB. Patients who have converted from a negative to a positive TB skin test should be considered candidates for prophylactic isoniazid therapy. Young children who have been in contact with persons with active TB are at high risk and should receive prophylactic antitubercular therapy. When a person is diagnosed with TB, family members are usually given prophylactic doses of isoniazid for 6 months to 1 year. For HIV-positive patients with positive TB skin tests, a 2-month prophylactic treatment with rifampin and pyrazinamide may be recommended.

Prophylactic therapy is contraindicated for persons with liver disease. Isoniazid is the primary antitubercular drug used and may cause isoniazid-induced liver damage. Other antitubercular drugs may also cause liver damage if given in high doses over an extended period.

Single-drug therapy with isoniazid proved ineffective in treating TB, because resistance to the drug developed in a short time. It was discovered that when a combination of antitubercular drugs was used, bacterial resistance did not occur, and the duration of treatment was reduced from 2 years to 6 to 9 months. Different combinations of drugs can be used: (1) isoniazid and rifampin; (2) isoniazid, rifampin, and ethambutol; or (3) isoniazid, rifampin, and pyrazinamide. Rifampin and ethambutol were discovered in the early 1960s; neither drug is effective against the tubercle bacillus when given alone. In fact, if rifampin is taken alone, bacterial resistance occurs quickly. Prototype Drug Chart 32-1 lists the drug data for isoniazid.

Multidrug therapy against TB is more effective. The treatment regimen is divided into two phases: the first, or initial, phase lasts 2 months, and the second phase covers the next 4 to 7 months. The total treatment plan is for 6 to 9 months and depends on the response to the antitubercular therapy. Table 32-1 gives examples of various drug regimens to treat TB.

If multidrug resistance to the tubercle bacilli persists, other antibacterial drugs such as the aminoglycosides (streptomycin, kanamycin, amikacin) or the fluoroquinolones (ciprofloxacin, ofloxacin) may be given as part of multidrug therapy. Susceptibility testing to determine drug resistance should be performed before drug therapy. At times, susceptibility testing of the sputum and antitubercular drugs is performed, but only if the patient has not responded to the drug therapy regimen.

Mycobacterium tuberculosis strains that are resistant to streptomycin can be sensitive to kanamycin. An aminoglycoside should not be taken if renal dysfunction is present. When antibacterial agents are used continuously or at high doses, the serum drug level should be closely monitored to avoid drug toxicity.

Pharmacokinetics Isoniazid is well absorbed from the gastrointestinal (GI) tract. It can also be administered intramuscularly (IM). It has a very low protein-binding rate (10%), and its half-life is 1 to 4 hours. Isoniazid is metabolized by the liver, and 75% of the drug is excreted in the urine.

Pharmacodynamics Isoniazid inhibits cell-wall synthesis of the tubercle bacillus. It is usually prescribed with other antitubercular

PROTOTYPE DRUG CHART 32-1

Isoniazid

Drug Class Antitubercular Trade names: INH, Nydrazid, 🍁 Isotamine Pregnancy Category: C	**Dosage** Prophylaxis: A: PO/IM: 300 mg/d; or 900 mg/d when 2×/wk for 9 mo C: PO/IM: 10-15 mg/kg/d 2-3×/wk; *max:* 900 mg/d Active tuberculosis: A: PO/IM: 5 mg/kg/d for 2 mo; then 15 mg/kg/d or 2-3×/wk; *max:* 900 mg/d C: PO/IM: 10-15 mg/kg/d for 6 mo
Contraindications Severe renal or hepatic disease, alcoholism, diabetic retinopathy	**Drug-Lab-Food Interactions** Drug: Increase effect with alcohol, rifampin, cycloserine, and phenytoin; decrease GI absorption while taking aluminum antacids Lab: Increase AST, ALT, bilirubin
Pharmacokinetics Absorption: PO: Well absorbed Distribution: PB: 10% Metabolism: t½: 1-4 h Excretion: 75% in urine	**Pharmacodynamics** PO: Onset: 0.5 h Peak: 1-2 h Duration: 6-8 h IM: Peak: 1-2 h Duration: 6 h
Therapeutic Effects/Uses To treat tuberculosis; prophylactic measure against tuberculosis Mode of Action: Inhibition of bacterial cell-wall synthesis	
Side Effects Drowsiness, tremors, rash, blurred vision, photosensitivity, tinnitus, dizziness, nausea, vomiting, dry mouth, constipation	**Adverse Reactions** Psychotic behavior, peripheral neuropathy, vitamin B_6 deficiency, hyperglycemia Life-threatening: Blood dyscrasias, seizures, thrombocytopenia, agranulocytosis, hepatotoxicity

A, Adult; *ALT*, alanine aminotransferase; *AST*, aspartate aminotransferase; *C*, child; *d*, day; *GI*, gastrointestinal; *h*, hour; *IM*, intramuscular; *max*, maximum; *mo*, month; *PB*, protein-binding; *PO*, by mouth; *t½*, half-life; *wk*, week; 🍁, Canadian drug name.

TABLE 32-1 POSSIBLE DRUG REGIMENS FOR TUBERCULOSIS

PHASE	EXAMPLE I	EXAMPLE II	EXAMPLE III	EXAMPLE IV
First phase (2 mo)*	isoniazid, rifampin	isoniazid, rifampin, pyrazinamide	isoniazid, rifampin, streptomycin	isoniazid, rifampin, pyrazinamide, kanamycin or ciprofloxacin
Second phase (4-7 mo)	isoniazid, rifampin	isoniazid, rifampin, ethambutol	isoniazid, rifampin, capreomycin or cycloserine	isoniazid, rifampin, ethambutol, streptomycin or kanamycin or ciprofloxacin or clarithromycin or capreomycin

mo, Month.

*If there is bacterial resistance to isoniazid, the first phase of the drug regimen may be rifampin, ethambutol, and pyrazinamide. Adjust drug regimen according to drug susceptibility. The health care provider determines which antitubercular drug and how many combinations to use. Symptoms for drug toxicity should be closely monitored. Examples III and IV may be used in various combinations for multidrug resistance.

agents. The onset of action and peak concentration time for oral and IM routes of isoniazid are the same. Peripheral neuropathy is an adverse reaction to isoniazid, so pyridoxine (vitamin B_6) is usually taken with isoniazid to decrease the probability of neuropathy. Alcohol ingestion with the drug can increase the incidence of peripheral neuropathy. If phenytoin is taken with isoniazid, the effect of phenytoin may be decreased. Antacids decrease isoniazid absorption.

Antitubercular drugs are divided into two categories: first-line and second-line. **First-line drugs** (drugs chosen first) (i.e., isoniazid, rifampin, rifabutin, rifapentine, pyrazinamide, ethambutol, streptomycin) are considered more effective and less toxic than second-line drugs in treating TB. Rifapentine, an analog of rifampin, is the newest first-line drug for treating TB. The patient takes it only twice a week, unlike rifampin, which is given daily. To avoid resistance, rifapentine should be combined with another antitubercular drug. **Second-line drugs** (second-choice drugs) (i.e., para-aminosalicylic acid, kanamycin, cycloserine, ethionamide, capreomycin, pyrazinamide, others) are not as effective as first-line drugs; some can be more toxic. Second-line drugs may be used in combination with first-line drugs, especially to treat disseminated TB. First-line and some second-line drugs are described in Table 32-2.

Side Effects and Adverse Reactions

Side effects and adverse reactions differ according to the drug prescribed. For isoniazid, peripheral neuropathy can be a problem, especially for those who are malnourished, have diabetes mellitus, or are alcoholics. This condition can be prevented if pyridoxine (vitamin B_6) is administered. **Hepatotoxicity** (liver toxicity) is an adverse reaction to isoniazid, rifampin, and streptomycin. Patients with liver disorders should not take these drugs unless liver enzymes are closely monitored, because liver enzymes may become elevated. The patient taking isoniazid, rifampin, and streptomycin may develop headaches, blood dyscrasias, paresthesias, GI distress, and ocular toxicity. Isoniazid may cause hyperglycemia,

TABLE 32-2 ANTITUBERCULAR DRUGS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
First-Line Drugs		
ethambutol HCl (Myambutol)	A: PO: 15-25 mg/kg/d; or 50 mg/kg 2×/wk; or 25-30 mg/kg 3×/wk for 2 mo	Used as a combination drug for active TB. Decrease dose if renal insufficiency is present. May cause leucopenia and thrombocytopenia. Pregnancy category: B; PB: 20%-30%; t½: 3-4 h
isoniazid (INH, Nydrazid)	See Prototype Drug Chart 32-1.	
pyrazinamide PZA	A/C: PO: 15-30 mg/kg/d or 50-70 mg/kg 2×/wk; *max:* 30 mg/kg/d	Used in combination with other antitubercular drugs for short-term and initial phase of therapy. Promote fluid intake. May cause photosensitivity, angioedema, hepatic failure, thrombocytopenia. Pregnancy category: C; PB: 5%-10%; t½: 9-10 h
rifabutin (Mycobutin)	A: PO: 300 mg/d in 1 or 2 divided doses	For *Mycobacterium tuberculosis* infection; to prevent disseminated *Mycobacterium avium* complex disease in patients with advanced HIV infection. Pregnancy category: B; PB: 85%; t½: average 45 h
rifampin (Rifadin)	A: PO: 600 mg/d C: PO: 10-20 mg/kg/d as a single dose for 9-12 mo; *max:* 600 mg/d	Used as a combination drug for active TB. For selective gram-positive and gram-negative bacteria, including *Neisseria meningitidis.* Monitor liver enzymes. Pregnancy category: C; PB: 80%; t½: 3-5 h
rifapentine (Priftin)	A: PO: 600 mg 2×/wk for 2 mo, then 600 mg 1×/wk for 4 mo	For TB. Interval between doses should be at least 72 h. Monitor for toxicity if drug is taken with an anticoagulant, anticonvulsant, or digoxin. Contraindicated with oral contraceptives. Pregnancy category: C; PB: 95%; t½: 13 h
streptomycin sulfate	A: IM: 15 mg/kg/d; *max:* 1 g/d C: IM: 20-40 mg/kg/d	Used against TB as the third drug with isoniazid and rifampin or with isoniazid and ethambutol. First drug used to treat TB. Pregnancy category: D; PB: 35%; t½: 2-3 h
Second-Line Drugs		
aminosalicylate sodium	A: PO: 14-16 g/d in 2-3 divided doses C: PO: 275-420 mg/kg/d in 3-4 divided doses; take with food	Second-line antitubercular drug. To treat pulmonary and extrapulmonary TB. Used in combination with other antitubercular drugs. Take after meals to reduce GI irritation. Pregnancy category: C; PB: 15%; t½: 1 h
capreomycin (Capastat)	A: IM: 15 mg/kg/d for 2-4 mo, then 2-3 ×/wk	Effective against *Mycobacterium tuberculosis,* but should be used in combination with other antitubercular drugs; not effective when used alone. Useful when bacillus is resistant to first-line drug. Hearing loss is an adverse reaction. Patient should take supplemental pyridoxine (vitamin B_6) to avoid peripheral neuropathy. Pregnancy category: C; PB: UK; t½: 4-6 h
ethionamide (Trecator SC)	A/C >12 y: PO: 15-20 mg/kg/q8h; *max:* 1 g/d	Effective against tubercle bacilli. Used when first-line drugs fail. Patient should take pyridoxine (vitamin B_6) to avoid peripheral neuropathy. Side effects include GI discomfort. *Caution:* Patients with diabetes mellitus, alcoholism, and hepatic disorder should be closely monitored when taking this drug. Pregnancy category: C; PB: 30%; t½: 2-3 h

Other Second-Line Drugs

Kanamycin, amikacin, ciprofloxacin, and ofloxacin are effective against tubercle bacilli in combination with antitubercular drugs. Chapter 29 includes more information about aminoglycosides, fluoroquinolones, and other antibacterial drugs.

A, Adult; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *HIV,* human immunodeficiency virus; *IM,* intramuscular; *max,* maximum; *mo,* month; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *TB,* tuberculosis; *UK,* unknown; *wk,* week; *y,* year; >, greater than.

hyperkalemia, hypophosphatemia, and hypocalcemia. Rifampin turns body fluids orange, and soft contact lenses may be permanently discolored. The patient taking ethambutol may develop dizziness, confusion, hallucinations, and joint pain. Streptomycin may lead to many adverse effects, such as ototoxicity, optic nerve toxicity, encephalopathy, angioedema, CNS and respiratory depression, nephrotoxicity, and hepatotoxicity.

SAFETY: Preventing Medication Errors

Do not confuse…

- **rifampin** with other antituberculars, such as **rifabutin** and **rifapentine**, or an antibiotic called **rifaximin,** used to treat diarrhea due to contaminated food or drinking water.

Nursing Process

Patient-Centered Collaborative Care

Antitubercular Drugs

Assessment

- Determine patient history of any past instances of tuberculosis, last purified protein derivative (PPD) tuberculin test and reaction, last chest radiograph and result, and any allergies to antitubercular drugs if taken previously.
- Obtain a general medical history from patient. Most antitubercular drugs are contraindicated if the patient has severe hepatic disease.

- Check laboratory tests for liver enzyme values, bilirubin, blood urea nitrogen (BUN), and serum creatinine. These baseline values can be compared with future laboratory test results.
- Evaluate patient for signs and symptoms of peripheral neuropathy (numbness or tingling of extremities).
- Assess patient for hearing changes if antitubercular drug regimen includes streptomycin. Ototoxicity is an adverse reaction to streptomycin.

Nursing Diagnoses

- Risk for infection related to inadequate primary defenses
- Disturbed sensory perception related to adverse effects of antituberculars
- Risk for impaired skin integrity related to side effects of antituberculars
- Risk for injury related to peripheral neuropathy secondary to side effects of antituberculars
- Knowledge deficit related to unfamiliarity with medications

Planning

- Patient's sputum test for acid-fast bacilli will be negative 2 to 3 months after the prescribed antitubercular therapy.

Nursing Interventions

- Administer the commonly ordered antitubercular drug isoniazid (INH) 1 hour before or 2 hours after meals. Food decreases absorption rate.
- Give pyridoxine (vitamin B_6) as prescribed with isoniazid to prevent peripheral neuropathy.
- Monitor serum liver enzyme levels, especially if patient takes isoniazid, rifampin, or streptomycin. Elevated levels may indicate liver toxicity.
- Collect sputum specimens for acid-fast bacilli early in the morning. Usually three consecutive morning sputum specimens are sent to the laboratory, and the routine is repeated several weeks later.
- Encourage eye examinations for patients taking isoniazid and ethambutol, because these antitubercular drugs may cause visual disturbances.
- Emphasize the importance of complying with the drug regimen.

Patient Teaching

General

- Tell patient to take antitubercular drug such as isoniazid 1 hour before meals or 2 hours after meals for better absorption.
- Direct patient to take antitubercular drugs as prescribed. Ineffective treatment of tuberculosis might occur if drugs are taken intermittently or discontinued when symptoms are decreased or patient is feeling better. *Compliance with the drug regimen is essential.*
- Teach patient not to take antacids while taking antitubercular drugs, because they decrease drug absorption. Patient should also avoid alcohol, because it may increase risk of hepatotoxicity.
- Advise patient to keep medical appointments and participate in sputum testing. Sputum testing is important in evaluating effectiveness of drug regimen.
- Warn patients contemplating pregnancy to first check with health care provider about taking the antitubercular drugs ethambutol and rifampin.

Side Effects

- Guide patient to report any numbness, tingling, or burning of hands and feet. Peripheral neuritis is a common side effect of isoniazid. Vitamin B_6 prevents peripheral neuropathy. Neuritis may not occur if patient eats a balanced diet daily.
- Encourage patient to avoid direct sunlight to decrease risk of photosensitivity. Patient should use sun block while in the sun.
- Inform patient taking rifampin that urine, feces, saliva, sputum, sweat, and tears may turn a harmless red-orange color. Soft contact lenses may be permanently stained.
- Alert patient receiving ethambutol to take daily single doses to avoid visual problems. Divided doses of ethambutol may cause visual disturbances.

Cultural Considerations

- Increase access to health care. Community involvement and culturally sensitive patient education are important. Explain to patients who have active tuberculosis that family members should get a TB skin test and may receive a prophylactic drug for 6 months to 1 year. Emphasize the importance of family members seeking medical care.
- Provide a written sheet for drug and treatment regimens in the language patient speaks or reads most easily. Explain importance of good hygiene (e.g., discarding tissues that contain sputum, separating dishes, using a dishwasher to clean dishes if possible).
- Understand significance of community if multiple individuals in the same community are treated for latent tuberculosis infection. Make all attempts to place community members on a treatment plan to increase compliance through social support.

Evaluation

- Evaluate effectiveness of the antitubercular drugs. Sputum specimen for acid-fast bacilli should be negative after taking antitubercular drugs for several weeks or months.

ANTIFUNGAL DRUGS

An infection caused by a fungus is also called *mycosis.* A fungal or mycotic infection may be superficial or systemic. Superficial fungal infections are acquired via contact with an infected person. Fungi, known as *dermatophytes,* cause superficial fungal infections involving the integumentary system, including mucous membranes, hair, nails, and moist skin areas. An overgrowth of nonsusceptible microorganisms in normal flora following antibiotic treatment may also cause a superficial fungal infection. When *Candida albicans* affects the mouth, it is called *oral candidiasis* or *thrush.* Vaginal candidiasis is common in women who are pregnant, diabetic, or taking antibiotics or oral contraceptives. Systemic fungal infections may involve the lungs, CNS, or abdomen. They are usually transmitted to an individual through inhalation into the lungs from dust, soil, or animal droppings. Fungal infections may be mild, such as tinea pedis (athlete's foot), or severe, such as pulmonary conditions or meningitis.

Fungal infections are also classified as *opportunistic* or *nonopportunistic infections.* **Opportunistic infections** usually occur in the immunocompromised or debilitated population (e.g., patients who have cancer or AIDS) or those taking antibiotics, corticosteroids, chemotherapy, or other immunosuppressives. Fungi such as the *Candida* spp. (yeast) are part of the normal flora of the mouth, skin, intestine, and vagina. An opportunistic infection such as *candidiasis* may occur when the body's defense mechanisms are impaired, allowing overgrowth of the fungus. Other opportunistic infections are *aspergillosis, cryptococcosis,* and *mucormycosis.* Nonopportunistic infections, such as *sporotrichosis, blastomycosis, histoplasmosis,* and *coccidioidomycosis,* can occur in any individual.

Antifungal drugs, also called **antimycotic drugs,** are used to treat fungal infections. Typically, antifungals are fungistatic or fungicidal depending upon the susceptibility of the fungus and the dosage. The antifungal drugs are classified into the following groups (Table 32-3):

- Polyenes (e.g., amphotericin B, nystatin)
- Azoles (e.g., ketoconazole)
- Antimetabolites (e.g., flucytosine)
- Echinocandins (e.g., caspofungin)
- Antiprotozoals (e.g., atovaquone)

Polyenes

Amphotericin B

The polyene antifungal drug of choice for severe systemic infection is amphotericin B. Introduced in 1956 and used currently with close supervision because of its toxicity, amphotericin B is effective against numerous fungal diseases, including *histoplasmosis, cryptococcosis, coccidioidomycosis, aspergillosis, blastomycosis,* and *candidiasis* (systemic infection).

TABLE 32-3 ANTIFUNGAL DRUGS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Polyenes		
amphotericin B (Fungizone)	A: IV: 0.3-1 mg/kg/d diluted in 500 mL D_5W over 2-6 h for 7-14 days using an inline filter and protection from light; *max:* 1.5 mg/kg/d	For a variety of systemic fungal (mycotic) infections, such as aspergillosis, blastomycosis, coccidioidomycosis, cryptococcosis, and histoplasmosis. Requires pretreatment with diphenhydramine, acetaminophen or ibuprofen, hydrocortisone. Nephrotoxicity may occur when given in high doses. Hypokalemia may occur. Pregnancy category: B; PB: 90%; t½: 24 h
nystatin (Mycostatin)	Intestinal infections: A: PO: 500,000-1,000,000 units t.i.d.	For *Candida* infections. Pregnancy category: C; PB: UK; t½: UK
Azoles		
fluconazole (Diflucan)	See Prototype Drug Chart 32-2.	
itraconazole (Sporanox)	A: PO: 200-400 mg/d	For various systemic fungal infections, particularly blastomycosis and histoplasmosis. Pregnancy category: C; PB: 99%; t½: 34-42 h
ketoconazole (Nizoral)	A: PO: 200-400 mg/d as single dose C >2 y: PO: 3.3-6.6 mg/kg/d as single dose	For *Candida* spp., histoplasmosis, blastomycosis, and other infections. Treatment may last 1 to 6 months for systemic infections. Take with food to avoid GI discomfort. Pregnancy category: C; PB: 84%-99%; t½: 2-8 h
miconazole nitrate (Monistat)	A/C >12 y: Intravaginal supp: 100 mg vaginal h.s. for 7 d; 200 mg for 3 d; 1200 mg single dose	For fungal meningitis and fungal bladder infections. Also for vaginal fungal infections. Pregnancy category: C; PB: 92%; t½: 24 h
voriconazole (Vfend)	A/C >40 kg: PO: 400 mg q12h on day 1, then 200 mg q12h C <40 kg: PO: 200 mg q12h on day 1, then 100 mg q12h A/C: IV: 6 mg/kg q12h on day 1, then 3-4 mg/kg q12h	For *Aspergillus* infection. Pregnancy category: D; PB: 58%; t½: 6 h
posaconazole (Noxafil)	A: PO: 100 mg/d up to-200 mg t.i.d. for 14-21 d	For prophylactic treatment of invasive *Aspergillus* and *Candida* infections in immunosuppressed patients. Pregnancy category: C; PB: 98%; t½: 35 h

Continued

TABLE 32-3 ANTIFUNGAL DRUGS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Antimetabolites		
flucytosine (Ancobon)	A: PO: 25 mg/kg q.i.d. for 7-10 d; *max:* 150 mg/kg/d TDM: 50-150 mcg/mL	Use with amphotericin B may increase therapeutic action as well as toxicity. Fungal resistance occurs if drug is given alone. Pregnancy category: C; PB: 2%-4%; t½: 3-6 h
Echinocandins		
caspofungin (Cancidas)	Loading dose: A: IV: 70 mg on day 1 Maintenance dose: A: IV: 50 mg/d over 1 h for 7-14 d	For *Aspergillus* infection. Pregnancy category: C; PB: 97%; t½: 9-11 h
micafungin (Mycamine)	A: IV: 100-150 mg/d over 1 h for 14-21 d	For esophageal candidiasis and prevention of *Candida* infection in patients having bone marrow transplantation. May cause GI distress, headache, and elevated liver enzymes. Pregnancy category: C; PB: 99%; t½: 14-17 h
anidulafungin (Eraxis)	Esophageal candidiasis: A: IV: 100 mg loading dose on day 1, then 50 mg/d IV for 7-14 days after last positive culture Other candidiasis infections: A: IV: 200 mg loading dose on day 1, then 100 mg/d IV for 14 days after last positive culture	For esophageal candidiasis, candidemia, and other *Candida* infections. Pregnancy category: C; PB: 99%; t½: 30-60 min
Antiprotozoals		
atovaquone (Mepron)	A: PO: 750 mg b.i.d. with food × 21 d	For mild to moderate *Pneumocystis carinii* pneumonia. Pregnancy category: C; PB: 99%; t½: 2-3 d
tinidazole (Tindamax)	A: PO: 2 g as a single dose for 3 days with food C >3 y: PO: 50 mg/kg as single dose for 3 days with food; *max:* 2 g	For giardiasis, intestinal amebiasis, trichomoniasis, and bacterial vaginosis. Pregnancy category: D (first trimester) and C (second and third trimesters); PB: 12%; t½: 12-14 h
Miscellaneous Antifungals		
griseofulvin (Fulvicin)	A: PO: 300-500; *max:* 750 mg microsize/d	For tinea capitis, tinea corporis, and tinea cruris. Pregnancy category: C; PB: UK; t½: 9-24 h

A, Adult; *b.i.d.,* twice a day; *C,* child; *d,* day; *D_5W,* 5% dextrose in water; *GI,* gastrointestinal; *h,* hour; *h.s.,* at bedtime; *inf,* infusion; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *min,* minute; *mo,* month; *PB,* protein-binding; *PO,* by mouth; *supp,* suppository; *t½,* half-life; *TDM,* therapeutic drug monitoring; *t.i.d.,* three times a day; *UK,* unknown; *y,* year; *>,* greater than; *<,* less than.

Polyene antifungals act by binding to the fungal cell membrane and forming open channels that increase cell permeability and leakage of intracellular components, especially potassium.

Pharmacokinetics Amphotericin B is highly protein-bound and has a long half-life. Only 5% of the drug is excreted in the urine. Renal disease does not affect the excretion of amphotericin B.

Pharmacodynamics Amphotericin B is not absorbed from the GI tract; therefore it is administered IV in low doses for treating systemic fungal infections. Peak effect occurs 1 to 2 hours after IV infusion, and the duration is 20 hours.

Side Effects and Adverse Reactions

Side effects and adverse reactions for amphotericin B include flush, fever, chills, nausea, vomiting, hypotension, paresthesias, and thrombophlebitis. Amphotericin B is considered *highly toxic* and can cause nephrotoxicity and electrolyte imbalance, especially hypokalemia and hypomagnesemia (low serum potassium and magnesium levels). Urinary output, blood urea nitrogen, and serum creatinine levels need to be closely monitored.

Nystatin

Nystatin (Mycostatin), another polyene antifungal drug, is administered orally or topically to treat *Candida* infection. It is available in suspensions, cream, ointment, and vaginal tablets. Nystatin is poorly absorbed via the GI tract; however, the oral tablet form is used for intestinal candidiasis. The more common use of nystatin is in oral suspension for *Candida* infection in the mouth. The patient is instructed to swish the liquid within the mouth, making contact with the mucous membrane, and then to swallow the liquid after a few minutes. If the throat area is involved, instruct the patient to gargle with nystatin after swishing and before swallowing.

Pharmacokinetics Nystatin is poorly absorbed. Its protein-binding power and half-life are unknown. The drug is excreted unchanged in the feces.

Pharmacodynamics Nystatin increases permeability of the fungal cell membrane, thus causing the fungal cell to become unstable and to discharge its content. This drug has a fungistatic and fungicidal action. The onset of action for both the suspension and tablet is rapid. The onset of action for vaginal tablet or cream is approximately 24 or more hours.

Azole Group

The azole group is effective against candidiasis (superficial and systemic), coccidioidomycosis, cryptococcosis, histoplasmosis, and paracoccidioidomycosis. Ketoconazole was the first effective antifungal drug that was orally absorbed. Fluconazole and itraconazole are also azole drugs used to treat systemic fungal infection. These antifungals can be taken orally, unlike amphotericin B and caspofungin, which are by IV route only. Fluconazole, a systemic azole antifungal agent, is described in Prototype Drug Chart 32-2.

Azoles inhibit cytochrome P450 in fungal cells, interfering with the formation of ergosterol. Because ergosterol is a major sterol in the fungal cell membrane, cell permeability and leakage are increased. Numerous azoles are used in topical preparations to treat candidiasis and the tinea infections. These drugs are available in forms of vaginal tablet, cream, ointment, and solution. Topical antifungal agents (azoles and others) are presented in Table 32-4.

HERBAL ALERT 32-1

Ketoconazole

When ketoconazole is taken with the herb echinacea, hepatotoxicity may develop.

Antimetabolite

The antimetabolite flucytosine acts by selectively penetrating the fungal cell, which converts it into fluorouracil, an antimetabolite that disrupts fungal DNA and RNA synthesis. It is well absorbed from the GI tract. Flucytosine is used in combination with other antifungal drugs, such as amphotericin B (see Table 32-3).

Echinocandins

The action of echinocandins is to inhibit biosynthesis of essential components of the fungal cell wall, which interferes with growth and reproduction. Caspofungin (Cancidas) is used to treat *Candida* and *Aspergillus* infections. This drug is only administered IV because it is not absorbed in the GI tract. Phlebitis at the IV site and increased AST and ALT are common adverse effects.

Antiprotozoal

Atovaquone (Mepron) is an antiprotozoal agent used to treat mild to moderate *Pneumocystis carinii* pneumonia. This drug acts by disrupting mitochondrial electron transport and inhibiting DNA synthesis.

PROTOTYPE DRUG CHART 32-2

Fluconazole

Drug Class
Antifungal
Trade Name: Diflucan
Pregnancy Category: C

Dosage
A: PO/IV: 400 mg/d × 1, then 200-400 mg/d for 4 wk
C: PO/IV: 12 mg/kg on day 1, then 6-12 mg/kg q72h

Contraindications
Hypersensitivity
Caution: Pregnancy

Drug-Lab-Food Interactions
Drug: Increases PT when taking warfarin; increases hypoglycemia when taken with oral sulfonylureas; increases phenytoin, cyclosporine, and haloperidol levels; decreases fluconazole level with cimetidine and rifampin

Pharmacokinetics
Absorption: PO: Well absorbed in GI tract
Distribution: PB: 12%
Metabolism: t½: 20-50 h
Excretion: In urine

Pharmacodynamics
PO: Onset: UK
Peak: 1-2 h
Duration: UK
Vag: Onset: UK
Peak: UK
Duration: UK

Therapeutic Effects/Uses
To treat *Candida* infections and cryptococcal meningitis
Mode of Action: Increase permeability of the fungal cell membrane

Side Effects
PO: Anorexia, nausea, vomiting, diarrhea (large doses), stomach cramps, rash, headache
Vaginal: Rash, burning sensation

Adverse Reactions
None known

A, Adult; *C,* child; *d,* day; *GI,* gastrointestinal; *h,* hour; *IV,* intravenous; *PB,* protein-binding; *PO,* by mouth; *PT,* prothrombin time; *t½,* half-life; *UK,* unknown; *wk,* week.

TABLE 32-4 TOPICAL ANTIFUNGAL AGENTS FOR FUNGAL INFECTIONS

			TINEA INFECTIONS		
DRUG	**DRUG FORM**	**CANDIDIASIS**	**TINEA PEDIS**	**TINEA CRURIS**	**TINEA CORPORIS**
Azoles					
butoconazole nitrate (Femstat)	2% vaginal cream	X			
clotrimazole (Femcare, Mycelex, Gyne-Lotrimin)	1% topical cream; vaginal tablet; PO: 1 troche (lozenge)	X	X	X	X
econazole (Spectazole)	1% topical cream	X	X	X	X
miconazole nitrate (Monistat, Micatin)	Vaginal suppository; 2% vaginal cream	X			
oxiconazole (Oxistat)	Cream		X	X	X
sulconazole (Exelderm)	Cream; solution		X	X	X
terconazole (Terazol-3)	Vaginal suppository; 0.4% and 0.8% vaginal cream	X			
Other Topical Antifungals					
ciclopirox olamine (Loprox)	Cream; lotion	X	X	X	X
haloprogin (Halotex)	1% cream; solution		X	X	X
naftifine (Naftin)	1% cream; gel		X	X	X
terbinafine HCl (Lamisil)	1% cream		X	X	X
tolnaftate (Aftate)	1% cream, gel, solution		X	X	X
sertaconazole (Ertaczo)	2% cream		X		

PO, By mouth.

Nursing Process
Patient-Centered Collaborative Care

Antifungals

Assessment
- Obtain a medical history from patient of any serious renal or hepatic disorder. Antifungal agents such as amphotericin B, fluconazole (Diflucan), flucytosine (Ancobon), and ketoconazole (Nizoral) are contraindicated if patient has a serious renal or liver disease.
- Check laboratory tests for liver enzyme values (alkaline phosphatase [ALP], alanine aminotransferase [ALT], aspartate aminotransferase [AST], gamma-glutamyl transferase [GGT]), blood urea nitrogen (BUN), bilirubin, and serum creatinine. Elevated levels can indicate liver or renal dysfunction. Use these test results for future comparison.
- Assess prior use of antifungals.
- Record baseline vital signs for future comparison.

Nursing Diagnoses
- Risk for infection related to poor health practices
- Impaired urinary elimination related to adverse effects of antifungals
- Deficient fluid volume related to side effects of antifungals

Planning
- Patient's fungal infection will be resolved.

Nursing Interventions
- Obtain a culture to determine fungus type (e.g., *Candida*).
- Monitor patient's urinary output; many antifungal drugs may cause nephrotoxicity.
- Check laboratory results, and compare with baseline findings (BUN, serum creatinine, ALP, ALT, AST, bilirubin, electrolytes). Certain antifungals could cause hepatotoxicity as well as nephrotoxicity when taking high doses over a prolonged period.
- Record vital signs. Compare with baseline findings.
- Observe for side effects and adverse reactions to antifungal drugs (antimycotics): nausea, vomiting, headache, phlebitis, signs and symptoms of electrolyte imbalance (hypokalemia with amphotericin B).

Patient Teaching
General
- Advise patient to take drug as prescribed. Compliance is of utmost importance, because discontinuing drug too soon may result in relapse.
- Monitor laboratory testing of serum liver enzymes, BUN, creatinine, and electrolytes.
- Inform patient taking ketoconazole not to consume alcohol.

Self-Administration
- Educate patient on administration of nystatin (Mycostatin) suspension: Place nystatin dose, usually 1 to 2 teaspoons, in the mouth. Swish solution in the mouth, and swallow afterward (swish and swallow).

Side Effects

- Teach patient to avoid operating hazardous equipment or a motor vehicle when taking amphotericin B, ketoconazole, or flucytosine, because these drugs may cause visual changes, sleepiness, dizziness, or lethargy.
- Encourage patient to report side effects (e.g., nausea, vomiting, diarrhea, dermatitis, rash, dizziness, tinnitus, edema, flatulence). These symptoms may occur when taking certain antifungal drugs.

Cultural Considerations

- Some cultures may not understand the purpose and procedure for the use of vaginal tablets or creams. A detailed explanation may be needed.
- Respect patient's apprehension and fear concerning the use of topical antifungal drugs and the desire to use alternative methods. Evaluate patient's method of topical administration in regard to safe practice. If the method is considered unsafe, explain why and suggest modifications. If appropriate, involve other persons for clarification.

Evaluation

- Evaluate the effectiveness of the antifungal (antimycotic) drug by noting the absence of the fungal infection (e.g., decrease in itching, redness, and rawness).

PEPTIDES

The two groups of **peptides** used as antibiotics are the polymyxins and bacitracin. Peptides are derived from cultures of *Bacillus subtilis,* and this group appears to interfere with bacterial cell membrane function.

Polymyxins

Polymyxins were one of the early groups of antibacterials, but many of the early drugs were discontinued because they caused nephrotoxicity. Polymyxin B is approved for pharmaceutical use. Polymyxins produce a bactericidal effect by interfering with the cell membrane of the bacterium, thereby causing cell death. They affect most gram-negative bacteria, such as *Pseudomonas aeruginosa, Escherichia coli, Klebsiella* spp., and *Shigella* spp.

Except for colistin, which exerts action on the colon and is excreted in the feces, the polymyxins are not absorbed through the oral route. Intramuscular injection of polymyxins produces marked pain at the injection site; therefore IV administration of polymyxins at a slow infusion rate is the suggested method. Table 32-5 lists the polymyxins with their dosage and uses.

Severe Adverse Effects

High serum levels of polymyxins can cause nephrotoxicity and neurotoxicity. With nephrotoxicity, the blood urea nitrogen and serum creatinine levels are elevated; however, when the serum drug level decreases, renal toxicity is usually reversed. Signs and symptoms of **neurotoxicity** (toxicity of the nerves) include **paresthesias** (abnormal sensations such as numbness, tingling, burning, and prickling) and dizziness. Neurotoxicity is usually reversible when the drug is discontinued.

Bacitracin

Bacitracin has a polypeptide structure and acts by inhibiting bacterial cell-wall synthesis and damaging the cell-wall membrane. The drug action can be bacteriostatic or bactericidal. Bacitracin is not absorbed by the GI tract and, if given orally, is excreted in the feces. Bacitracin is effective against most gram-positive bacteria and some gram-negative bacteria. Over-the-counter (OTC) bacitracin ointment is available for application to the skin.

Side Effects and Adverse Reactions

The side effects of bacitracin include redness, rash, nausea, and vomiting. Severe adverse reactions are renal damage and

TABLE 32-5 ANTIBACTERIALS: PEPTIDES

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Peptides		
Bacitracin (BaciiM, Baci-RX)	A/C: topical: Apply thin layer b.i.d. or t.i.d. A/C: ophthalmic ointment: Apply thin film to affected eye q3-4 h for 7-10 days	Topical ointment for skin infections; ophthalmic ointment for eye infections. Pregnancy category: C; PB: <20%; t½: UK
colistimethate sodium (Coly-Mycin M)	A/C: IM/IV: 2.5-5 mg/kg/d in divided doses; *max:* 5 mg/kg/d	For *Pseudomonas aeruginosa* infection. Pregnancy category: C; PB: UK; t½: 2-3 h
Additional Antibacterial Agents		
metronidazole (Flagyl, MetroGel)	A: PO: 250 mg t.i.d. or 500 mg b.i.d. for 7 days A: topical: Apply thin film to cleansed affected area	For serious gram-negative infections (e.g., UTI, septicemia, bacteremia, meningitis, *Pseudomonas aeruginosa*, skin infections) when other antibiotics are ineffective or contraindicated. Side effects may include GI discomfort, headache, and depression. Pregnancy category: B; PB: 10%; t½: 6-8 h

A, Adult; *C,* child; *d,* day; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *PB,* protein-binding; *sol,* solution; *t½,* half-life; *UK,* unknown; *y,* year; *>,* greater than; *<,* less than.

ototoxicity. Mild to severe allergic reactions ranging from hives to anaphylaxis may occur.

METRONIDAZOLE

Metronidazole (Flagyl) acts by impairing DNA function of susceptible bacteria. This drug is used primarily to treat various disorders associated with organisms in the GI tract. It is prescribed to treat intestinal amebiasis, trichomoniasis, inflammatory bowel disease, anaerobic infections, and bacterial vaginosis and is used as perioperative **prophylaxis** (prevention of infection) in colorectal surgery. Metronidazole is commonly used with other agents to treat *Helicobacter pylori,* which is associated with frequent recurrent peptic ulcers. Table 32-5 includes data related to metronidazole. The patient taking metronidazole should avoid alcohol and alcohol-containing medications for at least 48 hours after treatment is completed. Drug interaction with alcohol may produce a *disulfiram reaction* (facial flushing, severe headache, tachycardia, palpitations, hypotension, dyspnea, sweating, slurred speech, abdominal cramps, nausea, and vomiting).

Side Effects and Adverse Reactions

The side effects and adverse reactions of metronidazole include dizziness, headache, confusion, depression, irritability, weakness, and insomnia. The patient taking high doses of metronidazole may develop dark or reddish-brown urine. Dry mouth, metallic or bitter taste, and GI distress may occur. Paresthesias, nasal congestion, decreased libido, dysuria, incontinence, and ECG changes may develop.

KEY WEBSITES

Information on isoniazid: *www.nlm.nih.gov/medlineplus/druginfo/meds/a682401.html*

Information on fluconazole: *www.nlm.nih.gov/medlineplus/druginfo/meds/a690002.html*

CRITICAL THINKING CASE STUDY

CJ, a 41-year-old man, has had a constant cough and night sweats for several months. He consumes 1 pint of whiskey per day. Sputum is positive for acid-fast (tubercle) bacillus. The health care provider orders a 6- to 9-month antitubercular drug regimen (time of therapy to be determined according to sputum and radiograph test results). For 2 months, CJ takes isoniazid, rifampin, and pyrazinamide daily. The next 4 to 7 months, CJ takes isoniazid and rifampin biweekly.

1. What could be contributing causes for CJ's contracting tuberculosis? Give other contributing causes for contracting tuberculosis.
2. CJ received first-line antitubercular drugs for treatment of tuberculosis. How can the health professional determine whether the drugs are effective in eradicating the tubercle bacilli? Explain your answer.
3. What is the nurse's role in patient teaching concerning the drug regimen?
4. Name at least two serious adverse reactions that can occur when antitubercular drugs are given over an extended period.
5. What laboratory tests should be monitored while CJ takes isoniazid and rifampin? Why?

The health care provider orders pyridoxine to be given daily.

6. Give the rationale for the use of pyridoxine. What type of drug is it? What is its purpose, and when should it be administered?
7. What health agencies may the nurse suggest that could be helpful to CJ during and after therapy?

NCLEX STUDY QUESTIONS

1. A patient is beginning isoniazid and rifampin treatment for tuberculosis. The nurse gives the patient which instruction?
   a. Do not skip doses.
   b. Take the drugs t.i.d. with food.
   c. Take an antacid with the drugs to decrease GI distress.
   d. Take rifampin initially, and then begin isoniazid after 2 months.
2. A patient is taking isoniazid and is worried about the side effects. Which of the following does the nurse realize is an adverse effect of isoniazid?
   a. Ototoxicity
   b. Hepatotoxicity
   c. Nephrotoxicity
   d. Optic nerve toxicity

3. The nurse teaches a patient taking amphotericin B to report which signs and symptoms to the health care provider?
- **a.** Change in sight
- **b.** Decrease in hearing
- **c.** Decrease in urine
- **d.** Painful red rash and blisters

4. A patient with a diagnosis of intestinal amebiasis develops severe nausea, vomiting, fever, facial flushing, slurred speech, tachycardia, hypotension, and palpitations. An assessment reveals that the patient has just had several alcoholic beverages. The nurse should obtain a drug history for which drug?
- **a.** bacitracin (Baci-IM)
- **b.** fluconazole (Diflucan)
- **c.** metronidazole (Flagyl)
- **d.** ethambutol (Myambutol)

5. A patient has developed vaginal candidiasis. The nurse knows that which medication is appropriate treatment for this condition?
- **a.** terconazole (Terazol-3)
- **b.** haloprogin (Halotex)
- **c.** terbinafine (Lamisil)
- **d.** tolnaftate (Aftate)

6. A patient has been diagnosed with tuberculosis and is to begin the antitubercular medications isoniazid, rifampin, and ethambutol. What should the nurse do? (Select all that apply.)
- **a.** Encourage periodic eye examinations.
- **b.** Instruct the patient to take medications with meals.
- **c.** Suggest that the patient take antacids with medications to prevent GI distress.
- **d.** Advise the patient to report numbness and tingling of the hands or feet.
- **e.** Alert the patient that body fluids may develop a red-orange color.
- **f.** Teach the patient to avoid direct sunlight and to use sun block.

Answers: 1, a; 2, b; 3, c; 4, c; 5, a; 6, a, d, e, f.

CHAPTER 33

Antivirals, Antimalarials, and Anthelmintics

evolve WEBSITE

- Animations
- Content Updates
- Key Points
- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Explain the uses of antiviral and antimalarial drugs.
- Describe the various helminths and the human body sites used for their infestation.
- Differentiate the action of antivirals, antimalarials, and anthelmintics.
- Compare the side effects and adverse reactions of antiviral, antimalarial, and anthelmintic drugs.
- Apply the nursing process for the patient taking antimalarial and anthelmintic drug therapy.

OUTLINE

Viruses

VIRUSES

Viruses are more difficult to eradicate than most types of bacteria. A **virus** is an obligate intracellular organism that must reside within a living host cell to survive and reproduce. Viruses enter healthy cells and use their deoxyribonucleic acid (DNA) and ribonucleic acid (RNA) to generate more viruses. The growth cycle of viruses depends on the host cell enzymes and cell substrates for viral replication. Viruses live and reproduce when they are within living cells. Examples of common viral infections include influenza, herpes virus infections, and viral hepatitis infections.

Viral Infections

Influenza, also called *the flu,* is a highly contagious viral infection that affects the nose, throat, and lungs. This virus is seasonal and more prevalent from fall to spring. Influenza has three antigen types: A, B, and C. Influenza A causes a moderate to severe infection. Influenza B usually causes mild illness in children. Influenza C is very rare in humans. This viral infection is transmitted easily via contaminated droplets during coughing, sneezing, or talking. Droplets enter into the respiratory tract of the unaffected person and begin replication 24 hours before the appearance of symptoms. Usually influenza has an abrupt onset with the first symptoms being high fever, headache, fatigue, and myalgia (muscle aches). A sore throat, nonproductive cough, watery nasal discharge, weakness, red watery eyes, chills, and photophobia may also occur.

Herpesviruses are large viruses that cause infections. Among the most familiar are herpes simplex virus type 1 (HSV-1) and type 2 (HSV-2); varicella-zoster viruses (HSV-3 or VZV), more commonly known as *chickenpox* and *shingles*; Epstein-Barr virus (HSV-4 or EBV); and cytomegalovirus (HHV-5 or CMV). HSV-1 is usually associated with cold sores (vesicular lesions), which grow in neurons. The HSV-1 virus is capable of latency (ability to maintain disease potential without signs and symptoms). HSV-2 is usually associated with vesicular lesions and small ulcerations on the genitalia (genital herpes). The HSV-2 virus remains dormant by traveling through the peripheral nerves to the sacral dorsal root ganglia. The virus can be transported back the nerve root to the skin for reactivation at any time. While dormant, the virus continues to replicate. Both HSV-1 and HSV-2 are capable of causing recurrent infections. Both viruses can replicate in the mucous membranes and skin of the oropharynx or genitalia. The virus is transmitted by contact with infectious lesions or secretions. HSV-1 is spread by oral secretions from one individual to another. From the mouth, this virus can spread to the genital area by oral intercourse or poor hand washing. HSV-2 is usually spread by intimate sexual contact, or an infected mother can transmit the virus to her infant during childbirth. When signs and symptoms are present, they usually include eruption of small pustules and vesicles; fever; headache; malaise; myalgia; as well as tingling, itching, and pain in the genital area.

The varicella zoster virus (VZV or HSV-3) causes chickenpox and shingles. Chickenpox is a highly contagious viral infection that causes generalized pruritic vesicles and fever. It has become less common since a vaccine was developed; however, some outbreaks still occur. Shingles is a painful vesicular rash that can remain dormant in nerve cells. When a person who has previously been infected with chickenpox becomes older or develops a weakened immune system, the VZV can reactivate causing an outbreak along the region of skin innervated by the nerve where the virus resides. In addition to the rash, the patient may also develop fever, malaise, and myalgia.

Epstein-Barr virus (EBV or HSV-4) most commonly causes infectious mononucleosis, a condition manifested by fever, tonsillitis, and enlarged lymph nodes in the neck. EBV resides in lymphocytes, epithelial cells, and muscle cells and has a latency period.

Cytomegalovirus (CMV or HHV-5) is a very common infectious disease worldwide. It is thought that most adults have had this viral infection at one time and are unaware. Most individuals do not require treatment for CMV unless they are immunocompromised (e.g., babies or individuals who have had organ transplantations). CMV is transmitted via body fluids, especially saliva or urine; by kissing, sexual contact, or sharing food; or by a pregnant patient to the fetus. In susceptible individuals, CMV infection can lead to fatal pneumonia or blindness (due to an infected retina).

Hepatitis B (HBV) is a serious liver infection caused by the hepatitis B virus. The transmission of HBV is usually via a needlestick, intimate sexual contact, or childbirth. HBV is found in all body fluids, including blood, semen, and vaginal fluid. The signs and symptoms of HBV include anorexia, vomiting, diarrhea, jaundice, malaise, and myalgia.

A viral infection usually can be detected only after the virus has replicated itself. Viruses can cause mild to severe infections. General signs and symptoms of an acute viral infection include headache, low-grade fever (with a mild viral infection), nausea, vomiting, diarrhea, muscular pain, fatigue, and cough.

VACCINES

Vaccines are pharmacologic preparations that have been developed to provide immunity against and prevent diseases, such as smallpox, chickenpox, mumps, rabies, and influenza (see Chapter 36). The influenza virus vaccine may change annually because influenza (flu) virus changes its genetic structure each year. However, the influenza vaccine still promotes the production of antibodies by the immune system, despite the viruses' varying genetic structures. After influenza vaccination (flu shot), most individuals develop high antibody titer levels providing protection against similar circulating viral strains. Eggs are used to produce the flu vaccine; therefore any allergies to eggs should be determined before flu vaccine is administered to the patient. The success rate of vaccine use to prevent influenza in healthy children and adults is 65% to 90%. In older adults, vaccines are effective 60% of the time, but less than 60% if an older adult has multiple health problems.

DIAGNOSTIC TESTS FOR INFLUENZA

Several office laboratory tests can be used to diagnose influenza. The diagnostic test Directigen Flu A has been available for many years to detect influenza A; however, it does not detect influenza B. Flu OIA, QuickVue Influenza Test, and ZstatFlu are diagnostic tests that identify both influenza A and B. These tests use throat swabs, nasal swabs, or nasal aspiration. Results are available within 10 to 20 minutes. QuickVue tends to be easy and fast for a rapid diagnosis of influenza A and B.

ANTIVIRAL NON-HIV DRUGS

Antiviral drugs are used to prevent or delay the spread of a viral infection. They inhibit viral replication by interfering with viral nucleic acid synthesis in the cell. There are groups of antiviral drugs effective against various viruses, such as influenza A and B, herpes species, cytomegalovirus (CMV), and human immunodeficiency virus (HIV). Drugs for HIV are discussed in Chapter 35. The non-HIV antiviral drugs are listed in Table 33-1. Interferon alfa-2a and 2b are used to treat hepatitis B and C viruses (see Chapter 39).

Nonclassified Antivirals

The first two related antivirals, amantidine hydrochloride and rimantadine hydrochloride (Flumadine), were used to treat type A influenza. Both these antivirals are *nonclassified antivirals.* Originally, amantidine was used to treat parkinsonism and only later was found to be effective against influenza A. Neither amantidine nor rimantadine are effective against type B influenza. Three other nonclassified antivirals are (1) cidofovir, which is used to treat CMV retinitis; (2) foscarnet (Foscavir), which is used to treat HIV retinitis and herpes simplex infection in patients with **acquired immunodeficiency syndrome** (AIDS) (immune disorder characterized by opportunistic diseases); and (3) vidarabine (Vira-A), which is used to treat herpesvirus. In the late 1990s, the U.S. Food and Drug Administration (FDA) approved zanamivir (Relenza) and oseltamivir phosphate (Tamiflu), two drugs that inhibit the replication and spread of the influenza virus if given within 48 hours of symptoms; thus, early diagnosis of influenza is important.

Side Effects and Adverse Reactions

The side effects and adverse reactions to amantadine include central nervous system (CNS) effects, such as insomnia, depression, anxiety, confusion, and ataxia; orthostatic hypotension; neurologic problems, such as weakness, dizziness, and slurred speech; and gastrointestinal (GI) disturbances, such as anorexia, nausea, vomiting, and diarrhea. The CNS side effects of rimantadine occur less often than with amantadine.

Topical Antivirals

There are three topical antiviral drugs: idoxuridine (Herplex Liquifilm), penciclovir (Denavir), and trifluridine (Viroptic). These topical agents are used to treat herpes simplex viruses.

Neuraminidase Inhibitors

Neuraminidase inhibitors are a group of drugs that decrease the release of the virus from infected cells, thus decreasing viral spread and shortening the duration of flu symptoms. Zanamivir (Relenza) and oseltamivir phosphate (Tamiflu) are two neuraminidase inhibitors that should be taken within 48 hours of flu symptoms. These drugs inhibit the activity of neuraminidase, a viral glycoprotein, and are effective against type A and B influenza viruses. Zanamivir and oseltamivir phosphate are not substitutes for the "flu shot."

Gamma Globulin (Immune Globulin)

Gamma globulin (IgG) is rich in antibodies found in the blood. It provides a passive form of immunity to a virus by blocking the penetration of the virus into the host cell. It is administered during the early infectious stage of an illness to prevent a viral invasion in the body.

Human immune globulin (Gamastan) is administered intramuscularly (IM). A single-dose injection protects for approximately 2 to 3 weeks; it may be repeated 2 to 3 weeks following the first dose. For patients who need an immediate increase in immune globulin levels, intravenous (IV) immune globulin (Gamimune N) may be administered.

Purine Nucleosides

The synthetic purine nucleoside antiviral group is effective in interfering with the steps of viral nucleic acid (DNA) synthesis. Drugs in this group of nucleoside analogs include ribavirin (Virazole), acyclovir (Zovirax), famciclovir (Famvir), ganciclovir sodium (Cytovene), and valacyclovir (Valtrex). These drugs are effective in combating herpes simplex viruses (HSV-1, HSV-2), herpes zoster (shingles), varicella-zoster virus (chickenpox), and CMV. Valganciclovir (Valcyte) is a prodrug of ganciclovir and is effective for treating CMV retinitis in patients with AIDS.

The antiviral drug ribavirin was first marketed in 1986. It is used to treat respiratory syncytial virus (RSV) in children and respiratory infections caused by the influenza A and B viruses in older adults. Ribavirin is administered by aerosol.

Acyclovir

Acyclovir was introduced as an antineoplastic drug and later was found to be effective against herpesvirus, especially HSV-2, but also against HSV-1, herpes zoster (shingles), and CMV (which can cause congenital defects). There has been reported resistance to acyclovir as a result of the lack of viral-producing enzyme (thymidine kinase) needed to convert the drug to an effective antiviral compound. Prototype Drug Chart 33-1 lists the drug data for acyclovir sodium.

Pharmacokinetics Acyclovir is slowly absorbed, depending on the dose, and is widely distributed to body and organ tissues. Half the drug passes into the cerebrospinal fluid. The drug is 10% to 30% protein-bound. Its half-life is 2 to 3 hours with normal renal function. Acyclovir is excreted unchanged in the urine.

Pharmacodynamics Acyclovir interferes with the viral synthesis of DNA, thereby short-circuiting its replication. The onset of action for the oral preparation is unknown; for the intravenous (IV) route, the onset is rapid. Peak concentration time is within 2 hours for both routes of administration, and the duration of action for both is similar.

Probenecid can increase the effect of acyclovir. If an aminoglycoside or amphotericin B is taken with acyclovir, the incidence of nephrotoxicity is increased.

TABLE 33-1 NON-HIV ANTIVIRALS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Systemic Non-HIV Antivirals		
Nonclassified Antivirals		
amantadine HCl	Influenza A: A <65 y/C >9 y: PO: 200 mg/d in 1-2 divided doses Older adults >65 y: 100 mg/d C 1-8 y: PO: 5 mg/kg/d in 2 divided doses	Primary use is prophylaxis against influenza A. Well absorbed by GI tract. Pregnancy category: C; PB: UK; t½: 11-15 h
cidofovir (Vistide)	A: IV: 5 mg/kg in 100 mL NS over 60 minutes once/wk for 2 wk, then 3-5 mg/kg every other week. Take probenecid 2 g, 3 h before infusion, and take 1 g, 8 h after infusion.	For CMV retinitis, especially in patients with AIDS. Kidney damage may occur; monitor kidney function. Pregnancy category: C; PB: UK; t½: 17-65 h
foscarnet (Foscavir)	CMV retinitis: A: IV: 60 mg/kg infused over 1 h, q8h, for 2-3 wk or 90 mg/kg/d infused over 2 h, q12h	For herpesviruses (HSV-1 and HSV-2, VZV) and CMV retinitis. Can cause kidney damage and hyperphosphatemia. Closely monitor kidney function. Does not cause granulocytopenia or thrombocytopenia. Pregnancy category: C; PB: UK; t½: 3-7 h
rimantadine HCl (Flumadine)	A/C >10 y: PO: 100 mg b.i.d. Older adults: PO: 100 mg/d	For prophylaxis and treatment against influenza A virus. Drug dose is usually reduced for patients with severe hepatic or renal impairment. Pregnancy category: C; PB: 40%; t½: 13-65 h
Influenza virus vaccine (FLUCELVAX, Flublok)	Flublok: A: IM: 0.5 mL as single dose at beginning of influenza season	Flublok is for prophylaxis against influenza subtypes A and type B. Given IM only in deltoid muscle of upper arm at the beginning of influenza season. FLUCELVAX is for treatment of influenza subtypes A and B. Given IM only in deltoid muscle of upper arm. Pregnancy category: C; PB: UK; t½: UK
telbivudine (Tyzeka)	A: PO: 600 mg/d	For chronic HBV. Pregnancy category: B; PB: 3.3%; t½: 40-49 h.
adefovir dipivoxil (Hepsera)	A/C >12 y: PO: 10 mg/d	For chronic HBV. Pregnancy category: C; PB: <4%; t½: 7.5 h.
entecavir (Baraclude)	A: PO: 0.5-1 mg/d 2 h a.c. or p.c.	For chronic HBV. Pregnancy category: C; PB: 13%; t½: 128-149 h.
Purine Nucleosides		
acyclovir (Zovirax)	See Prototype Drug Chart 33-1.	
famciclovir (Famvir)	Herpes zoster: A: PO: 500 mg q8h × 7 d Herpes simplex: A: PO: 125 mg b.i.d. × 5 d or 1000 mg b.i.d. for 1 d	For herpes zoster and HSV-1. Pregnancy category: B; PB: <20%; t½: 2-3 h
Varicella-zoster immune globulin (VariZIG)	A/Adol >40 kg: IM: 625 international units/dose within 96 h of exposure C 10-20 kg: 250 international units/dose IM within 96 h of exposure	For postexposure prophylaxis of varicella zoster. Pregnancy category: C; PB: UK; t½: 22-30 d
ganciclovir sodium (Cytovene)	A/C: IV: Initially: 5 mg/kg over 1 h q12h × 14-21 d; *maint:* 5 mg/kg/d over 1 h for 7 d, or 6 mg/kg/d over 1 h for 5 d	For CMV systemic infection in immunocompromised patients. Pregnancy category: C; PB: 1%-2%; t½: 2.5-6 h
ribavirin (Virazole)	RSV: C: Aerosol inhalation: 20 mg over 12-18 h/d for 3-7 d Hepatitis C: A >75 kg: PO: 600 mg b.i.d. for 24-48 wk A <75 kg: PO: 400 mg in morning and 600 mg in evening C: PO: 15 mg/kg/d	For respiratory syncytial viral infection in infants and children and for hepatitis C. Pregnancy category: X; PB: NA; t½: 44 h
valacyclovir HCl (Valtrex)	Herpes zoster: A: PO: 1 g t.i.d. for 7 d Recurrent genital herpes: A: PO: 500 mg b.i.d. for 3 d	Effective against VZV causing herpes zoster (shingles) and recurrent genital herpes. Monitor kidney function. Encourage patient to increase water intake. GI disturbances and headaches are common side effects. Pregnancy category: B; PB: 14%-18%; t½: 2.5-3.5 h
valganciclovir (Valcyte)	A: PO: 900 mg b.i.d. with food for 21 d	To treat CMV-infected cells of retinitis in AIDS patients. Inhibits viral DNA synthesis. May cause leukopenia, thrombocytopenia, bone marrow depression, and aplastic anemia. Pregnancy category: C; PB: 1%-2%; t½: 18 h

Continued

TABLE 33-1 NON-HIV ANTIVIRALS—cont'd

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Neuraminidase Inhibitors		
oseltamivir phosphate (Tamiflu)	A/C >40 kg: PO: 75 mg b.i.d. for 5d C 23-40 kg: PO: 60 mg b.i.d. for 5d C 15-23 kg: PO: 45 mg b.i.d. for 5d C <15 kg: PO: 30 mg b.i.d. for 5d	For uncomplicated acute influenza A and B. Treatment should begin within 48 h of flu symptoms. May be taken with or without food. Side effects include transient nausea and vomiting. Pregnancy category: C; PB: 3%, t½: 1-3 h
zanamivir (Relenza)	A: inhaler: 2 oral inhalations (one 5-mg blister/inhalation) b.i.d. for 5 d	For influenza A and B and H1N1 influenza. Treatment should begin within 48 h of flu symptoms. Less than 20% absorbed systemically. Pregnancy category: C; PB: <10%; t½: 2.5-5 h
Topical Non-HIV Antivirals		
penciclovir (Denavir)	A: topical: Apply cream q2h during the day for 4 d	For recurrent herpes labialis (cold sores). Pregnancy category: B; PB: UK; t½: UK
trifluridine (Viroptic)	A: ophthalmic solution: 1 gt q2h during the day; *max:* 9 gtt/d	Used primarily for keratoconjunctivitis due to herpes simplex virus. Pregnancy category: C; PB: UK; t½: 12 min

A, Adult; a.c., before meals; *AIDS,* acquired immunodeficiency syndrome; *b.i.d.,* twice a day; *C,* child; *CMV,* cytomegalovirus; *d,* day; *DNA,* deoxyribonucleic acid; *GI,* gastrointestinal; *gt,* drop; *gtt,* drops; *h,* hour; *HIV,* human immunodeficiency virus; HSV, herpes simplex virus; *IV,* intravenous; *maint,* maintenance; *max,* maximum; *PB,* protein-binding; p.c. after meals; *PO,* by mouth; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *VZV,* varicella-zoster virus; *wk,* week; *y,* year; *>,* greater than; *<,* less than.

PROTOTYPE DRUG CHART 33-1

Acyclovir Sodium

Drug Class Antiviral Trade Name: Zovirax Pregnancy Category: B	**Dosage** Herpes simplex virus: A: PO: 400 mg t.i.d. for 5-10 d A: IV: 5 mg/kg q8h for 10-21 d Herpes zoster virus: A: PO: 800 mg q4h 5 ×/d for 7-10 d Herpes simplex encephalitis: A: IV: 10 mg/kg q8h for 10 d
Contraindications Hypersensitivity, severe renal or hepatic disease Caution: Electrolyte imbalance, dehydration, seizure disorder, nursing mothers, young children	**Drug-Lab-Food Interactions** Drug: Increase nephro-neurotoxicity with aminoglycosides, probenecid, interferon; decreases effect of phenytoin Lab: May increase AST, ALT, BUN
Pharmacokinetics Absorption: PO: Slowly absorbed Distribution: PB: 10%-30% Metabolism: t½: PO: 2.5-3 h Excretion: Urine and breast milk	**Pharmacodynamics** PO: Onset: UK Peak: 1.5-2 h Duration: 4-8 h IV: Onset: Rapid Peak: 1-2 h Duration: 4-8 h
Therapeutic Effects/Uses To treat HSV-1, HSV-2 (genital) Mode of Action: Interference with viral synthesis of DNA	
Side Effects Nausea, anorexia, vomiting, diarrhea, headache, tremors, agitation, lethargy, rash, pruritus, increased bleeding time, phlebitis at IV site	**Adverse Reactions** Urticaria, anemia, crystalluria, paresthesias Life-threatening: Neuropathy, seizures, nephrotoxicity (large doses), thrombocytopenia, leukopenia,

A, Adult; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *BUN,* blood urea nitrogen; *C,* child; *d,* day; *DNA,* deoxyribonucleic acid; *h,* hour; *HSV,* herpes simplex virus; *IV,* intravenous; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown.

Valacyclovir (Valtrex) is converted to acyclovir, which has inhibitory activity against HSV-1, HSV-2, and varicella-zoster or herpes zoster viruses. With herpes zoster, valacyclovir offers a greater decrease in pain and an increase in healing time (40 to 43 days) than with acyclovir (59 days).

Famciclovir (Famvir), an antiviral drug developed before valacyclovir, is equally effective as acyclovir for treating acute herpes zoster.

Nursing Process

Patient-Centered Collaborative Care

Antiviral: Acyclovir

Assessment

- Obtain a medical history from patient of any serious renal or hepatic disease.
- Determine baseline vital signs and a complete blood count (CBC). Use these findings for comparison with future results.
- Assess baseline laboratory results, particularly blood urea nitrogen (BUN), serum creatinine, liver enzymes, bilirubin, and electrolytes. Use these results for future comparison.
- Evaluate baseline vital signs and urine output. Report abnormal findings.

Nursing Diagnoses

- Risk for infection related to insufficient knowledge about avoiding exposure to pathogens
- Risk for injury related to adverse effects of antivirals as evidenced by gingival hyperplasia and bone marrow depression
- Risk for impaired skin integrity related to adverse effects of antivirals as evidenced by rash and pruritus
- Deficient knowledge related to inexperience with antiviral medications.

Planning

- Patient's symptoms of viral infections will be eliminated or diminished.

Nursing Interventions

- Check patient's CBC. Report abnormal results (leukopenia, thrombocytopenia, low hemoglobin and hematocrit).
- Monitor other laboratory tests (BUN, serum creatinine, liver enzymes); compare with baseline values.
- Record patient's urinary output. An antiviral drug such as acyclovir can affect renal function.
- Monitor vital signs, especially blood pressure. Acyclovir and amantadine may cause orthostatic hypotension.
- Observe for signs and symptoms of side effects. Most antiviral drugs have many side effects (see Prototype Drug Chart 33-1).
- Check for superimposed infection (superinfection) caused by high dose and prolonged use of an antiviral drug such as acyclovir.
- Administer oral acyclovir as prescribed. Oral dose can be taken at mealtime.
- Dilute the antiviral drug in an appropriate amount of solution as indicated in the drug circular when giving IV. Administer IV drug over 60 minutes. Never give acyclovir as a bolus (IV push).

Patient Teaching

General

- Advise patient to maintain adequate fluid intake to ensure sufficient hydration for drug therapy and increase urine output.
- Instruct patient with genital herpes to avoid spreading infection by practicing sexual abstinence or by using condoms. Teach women with genital herpes to have a Pap test done as indicated by health care provider. Cervical cancer is more prevalent in those with genital herpes simplex.
- Direct patients taking zidovudine to have blood cell count monitored.

Side Effects

- Encourage patient to perform oral hygiene several times a day. Gingival hyperplasia (red, swollen gums) can occur with prolonged use of antiviral drugs.
- Guide patient to report adverse reactions, including decrease in urine output and central nervous system changes such as dizziness, anxiety, or confusion.
- Warn patient with dizziness resulting from orthostatic hypotension to arise slowly from a sitting to a standing position.
- Tell patient to report any side effects associated with the antiviral drug: nausea, vomiting, diarrhea, increased bleeding time, rash, urticaria, menstrual abnormalities.

Cultural Considerations

- Teach non–English-speaking patients and family members how to use ophthalmic preparations by using materials in the patients' first language. Pictures may be helpful.

Evaluation

- Evaluate the effectiveness of the antiviral drug in eliminating the virus or in decreasing symptoms.
- Determine whether or not side effects are absent.

Ganciclovir (Cytovene, Vitrasert) is effective in treating the herpesviruses and CMV. Its primary use is to treat CMV infections. It has serious adverse reactions.

Side Effects and Adverse Reactions. Side effects and adverse reactions to acyclovir and ganciclovir include GI disturbances (e.g., nausea, vomiting, diarrhea).

Acyclovir may cause headache, dizziness, and hematuria. Insomnia, depression, and hypotension, although infrequent, can also occur. Elevated blood urea nitrogen (BUN) and serum creatinine levels can result from renal involvement; such involvement is usually transient.

Ganciclovir can cause thrombocytopenia and granulocytopenia. Because of the possible serious adverse reactions, this drug should be prescribed primarily for severe systemic CMV infections for immunocompromised patients.

ANTIVIRAL HIV DRUGS

The microbe of the human immunodeficiency virus (HIV) is the cause of AIDS. HIV is a retrovirus. There are two classes of antiretroviral drugs: (1) reverse transcriptase inhibitors and (2) protease inhibitors. Antiviral drugs classified as reverse transcriptase inhibitors include delavirdine (Rescriptor), didanosine (Videx), lamivudine (Epivir), nevirapine (Viramune), stavudine (Zerit), and zidovudine (Retrovir, AZT). These drugs aid in inhibiting viral replication. Zidovudine was one of the first retroviral drugs approved by the FDA. It inhibits the action of viral reverse transcriptase, thus preventing the synthesis of DNA and allowing the T_4 lymphocytes to increase initially.

The protease inhibitor group includes indinavir (Crixivan), nelfinavir (Viracept), ritonavir (Norvir), and saquinavir (Invirase). This group of antivirals inhibits the replication of retroviruses (HIV-1 and HIV-2). When a protease inhibitor is used in combination with a reverse transcriptase inhibitor, these drugs may greatly reduce the viral level to the point that it is undetectable. The combination of drugs helps decrease HIV drug resistance. Antiviral drugs for suppressing HIV are discussed in Chapter 35.

ANTIMALARIAL DRUGS

Malaria, caused by the protozoan parasites *Plasmodium* spp. carried by infected *Anopheles* mosquitoes, is still one of the most prevalent protozoan diseases. After the mosquito infects the human, the protozoan parasite passes through two phases: the tissue phase and the erythrocytic phase. The **tissue phase** (invasion of body tissue) produces no clinical symptoms in the human, but the **erythrocytic phase** (invasion of the red blood cells) causes symptoms of chills, fever, and sweating. The incubation period is 10 to 35 days, followed by flulike symptoms.

There are approximately 50 species of *Plasmodium,* and 4 types of the species cause malaria: *P. malariae, P. ovale, P. vivax,* and *P. falciparum. P. vivax* is the most prevalent; *P. falciparum* is the most severe. Throughout the world there are about 200 million cases of malaria, but in the United States malaria is confined mainly to persons who enter the country from elsewhere. The incidence of malaria has increased since 1960, primarily because of travel to regions in the world where malaria is endemic, and drug-resistant malaria parasites.

Treatment of malaria depends on the type of *Plasmodium* and the organism's life cycle. Quinine was the only antimalarial drug available from 1820 until the early 1940s. Synthetic **antimalarial drugs** have since been developed that are as effective as quinine and cause fewer toxic effects. When drug-resistant malaria occurs, combinations of antimalarials are used to facilitate effective treatment. Chloroquine is a commonly prescribed drug for malaria. If drug resistance to chloroquine occurs, another antimalarial (e.g., mefloquine HCl, or combinations of antimalarials with or without antibiotics (e.g., tetracycline, doxycycline, clindamycin) may be prescribed.

Three methods used to eradicate malaria are **prophylaxis** (prevention) of malaria, treatment for the acute attack, and prevention of relapse. Many synthetic antimalarials (chloroquine, primaquine) are used prophylactically. Chloroquine and mefloquine are frequently used to treat an acute malarial attack. Mefloquine HCl and the combination drug atovaquone/proguanil (Malarone) are used to treat chloroquine-resistant *P. falciparum.* Chloroquine and hydroxychloroquine can be toxic to children and may even cause death; therefore the drug dose should be closely monitored. Prototype Drug Chart 33-2 lists the drug data for chloroquine HCl.

Pharmacokinetics Chloroquine HCl is well absorbed from the GI tract. It is moderately protein-binding, and the drug has a long half-life. The first two doses have a loading dose effect. Because of its long half-life, the next dose is given in 6 hours, the third and fourth doses are given at 24 and 48 hours, and then a dose is given once a day for 2 days. Chloroquine is metabolized in the liver to active metabolites and excreted in the urine.

Pharmacodynamics Chloroquine HCl inhibits the malaria parasite's growth by interfering with its protein synthesis. Whether the drug is given orally or IM, the onset of action is rapid. The peak effect is slower when given orally. The duration of effect of the drug is very long—days to weeks.

Side Effects and Adverse Reactions

General side effects and adverse reactions to antimalarials include GI upset, cranial nerve VIII involvement (quinine and chloroquine), renal impairment (quinine), and cardiovascular effects (quinine).

Table 33-2 lists commonly ordered antimalarial drugs and their dosage, uses, and considerations. Note: Quinine is an antimalarial drug, and quinidine is an antidysrhythmic drug. A medication guideline developed by the FDA accompanies mefloquine each time it is dispensed. This type of guideline is used only for drugs that require monitoring for serious adverse effects. Adverse effects that may occur after mefloquine use include severe anxiety, restlessness, disorientation, depression, hallucinations, paranoia, and suicidal thoughts.

SAFETY: Preventing Medication Errors

Do not confuse…

- **quinine** (antimalarial) with **quinidine** (antidysrhythmic)

PROTOTYPE DRUG CHART 33-2

Chloroquine HCl

Drug Class

Antimalarial

Trade Name: Aralen HCl

Pregnancy Category: C

Dosage

Acute malaria:

A: PO: 1000 mg/dose; then 500 mg/dose in 6 h; then 500 mg/d at 24 h and 48 h

C/Adol: PO: 16.5 mg/kg, then 8.3 mg/kg in 6 h, 24 h, and 36 h

Prophylaxis:

2 wk before and for 6-8 wk after exposure

A: PO: 500 mg/wk

C: PO: 8.3 mg/kg/wk

Contraindications

Hypersensitivity, renal disease, psoriasis

Caution: Alcoholism; liver dysfunction; G-6-PD deficiency; GI, neurologic (seizures, hearing impairment), and hematologic disorders

Drug-Lab-Food Interactions

Drug: Increase effects of digoxin, neuromuscular blocker; decrease absorption with antacids and laxatives

Lab: Elevated liver enzymes; decreased red blood cell count, hemoglobin, hematocrit

Food: Lemon juice decreases effects

Pharmacokinetics

Absorption: Well absorbed from GI tract

Distribution: PB: 50%-65%

Metabolism: t½: 1-2 months

Excretion: Excreted slowly in urine

Pharmacodynamics

PO: Onset: Rapid

Peak: 1-2 h

Duration: Days to weeks

Therapeutic Effects/Uses

To treat acute malaria; prophylaxis for malaria

Mode of Action: Increased pH in the malaria parasite inhibits parasitic growth

Side Effects

Anorexia, nausea, vomiting, diarrhea, abdominal cramps, fatigue, pruritus, headache, nervousness, visual impairment, insomnia, photosensitivity, hair discoloration

Adverse Reactions

ECG changes, hypotension, psychosis, seizures

Life-threatening: Agranulocytosis, aplastic anemia, thrombocytopenia, ototoxicity, cardiovascular collapse

A, Adult; *Adol,* adolescent; *C,* child; *d,* day; *ECG,* electrocardiogram; *G-6-PD,* glucose-6-phosphate dehydrogenase; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *t ½,* half-life; *wk,* week.

Nursing Process

Patient-Centered Collaborative Care

Antimalarials

Assessment

- Assess patient's hearing, especially if receiving quinine or chloroquine. These drugs may affect cranial nerve VIII.
- Check patient for visual changes. Patients who take chloroquine and hydroxychloroquine should have frequent ophthalmic examinations.

Nursing Diagnoses

- Risk for infection related to insufficient knowledge about avoiding exposure to malarial pathogens
- Risk for impaired skin integrity related to fever and excessive sweating
- Risk for imbalanced nutrition: less than body requirements related to side effects of vomiting and diarrhea
- Risk for visual injury related to side effects of blurred vision
- Deficient knowledge related to inexperience with antimalarial medications.

Planning

- Patient will be free of malarial symptoms.

Nursing Interventions

- Monitor patient's renal and liver function by checking urine output (>600 mL/d) and liver enzymes. Antimalarial drugs concentrate first in the liver; if patient drinks considerable amounts of alcohol or has a liver disorder, liver enzymes require closer monitoring. Renal impairment may occur as an adverse effect of antimalarials.
- Report if patient's serum liver enzymes are elevated or renal function tests are abnormal.

TABLE 33-2 ANTIMALARIALS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
chloroquine HCl (Aralen HCl)	See Prototype Drug Chart 33-2.	
hydroxychloroquine sulfate (Plaquenil sulfate)	Acute malaria: A: PO: 800 mg, then 400 mg at 6, 18, 24, and 36 h C: PO: 13 mg/kg/dose, then 6.5 mg/kg in 6, 18, and 24 h	Alternative to chloroquine. Dosage varies for treating malaria. Can be used adjunctively with primaquine. Give with meals to reduce GI distress. Pregnancy category: C; PB: 45%; t½: 32-50 d
mefloquine HCl	Malaria treatment: A: PO: Single dose: 1250 mg Malaria prophylaxis: A: PO: 250 mg/wk for 1-2 wk before travel and 4 wk after; take with plenty of water	Prophylaxis and treatment of acute malaria. Treatment of choice in U.S. for malaria. Pregnancy category: C; PB: 98%; t½: 10-21 d
primaquine phosphate (Primaquine)	Malaria treatment: A: PO: 15-mg base/d for 14 d Malaria prophylaxis: A: PO: 30-mg base/d for 14 d	For malaria caused by *Plasmodium vivax*, *P. ovale*, and *P. falciparum*, as well as *Pneumocystis carinii* pneumonia. Can affect WBC production (granulocytopenia) and cause acute hemolytic anemia in patients with G-6-PD deficiency. Pregnancy category: C; PB: UK; t½: 3.7-9.6 h
pyrimethamine (Daraprim)	Malaria prophylaxis: A/C >10 y: PO: 25 mg/wk for 2 wk before exposure and continue for 10 wk after C 4-10 y: PO: 12.5 mg/wk C <4 y: PO: 6.25 mg/wk Malaria treatment: A/C >10 y: PO: 25 mg/d for 2 d with a sulfonamide C 4-10 y: PO: 25 mg/d for 2 d	Prophylaxis use for malaria. For chloroquine-resistant *P. falciparum* infections. May be used with quinacrine, quinine, or chloroquine. Pregnancy category: C; PB: 80%-87%; t½: 80-123 h
quinine sulfate (Qualaquin)	Acute malaria: A: PO: 650 mg q8h for 3-7 d	Used in combination drug therapy or for chloroquine-resistant malaria. Pregnancy category: C; PB: 70%; t½: 8-21 h
Combination Antimalarial Drugs		
atovaquone/proguanil (Malarone)	A/C >40 kg: PO: 250/100-mg tabs: 3 tabs/d for 3 d C 31-40 kg: PO: 250/100-mg tabs: 2 tabs/d for 3 d C 11-20 kg: PO: 250/100-mg tabs: 1 tab/d for 3 d	For oral prophylaxis and treatment of malaria. Effective for chloroquine-resistant strains. Pregnancy category: C; PB: 99%/75%; t½: 2-3 d/12-20 h
artemether/lumefantrine (Coartem)	A/C >35 kg: PO: 4 tabs of artemether 80 mg/lumefantrine 480 mg upon diagnosis, then 4 tabs in 8 h, then 4 tabs b.i.d. for 2 d A/C 25-35 kg: PO: 3 tabs artemether 60 mg with lumefantrine 360 mg in same regimen C 15-25 kg: PO: 2 tabs artemether 40 mg with lumefantrine 240 mg in same regimen C 5-15 kg: PO: 1 tab artemether 20 mg with lumefantrine 120 mg in same regimen	For malaria infections that are both drug-sensitive and drug-resistant to *Plasmodium falciparum.* Acts by inhibiting nucleic acid and protein synthesis. Rapid onset allows drug to control fever quickly. Has a high cure rate. Adverse effects include nystagmus, wheezing, hypokalemia, blood dyscrasias, and hepatomegaly. Pregnancy category: C; PB: 95%/99%; t½: 2-3 h/3-6 d

A, Adult; *C,* child; *d,* day; *G-6-PD,* glucose-6-phosphate dehydrogenase; *GI,* gastrointestinal; *h,* hour; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *tab,* tablet; *UK,* unknown; *wk,* week; *y,* year; *>,* greater than; *<,* less than.

Patient Teaching

General

- Advise patients traveling to malaria-infested countries to receive prophylactic doses of antimalarial drug before leaving, during the visit, and upon return.
- Teach patient to take oral antimalarial drugs with food or at mealtime if GI upset occurs.
- Monitor patient returning from a malaria-infested area for malarial symptoms.
- Inform patient who takes chloroquine or hydroxychloroquine to report vision changes immediately.
- Warn patient to avoid consuming large quantities of alcohol.

Side Effects

- Direct patient to report signs and symptoms of anorexia, nausea, vomiting, diarrhea, abdominal cramps, pruritus, visual disturbances, and dizziness.

Cultural Considerations

- Advise patient from a malaria-infested country to be tested for malaria if patient complains of chills, high fever, and profuse sweating.
- Patient may receive an antimalarial drug as a prophylactic measure or for treatment of an acute attack. Explanation is necessary so patient complies with the drug regimen.

Evaluation

- Evaluate the effectiveness of the antimalarial drug by determining that patient is free of symptoms.
- Evaluate patient's understanding of medication regimen.

ANTHELMINTIC DRUGS

Helminths are large organisms (parasitic worms) that feed on host tissue. The most common site for **helminthiasis** (worm infestation) is the intestine. Other sites for parasitic infestation are the lymphatic system, blood vessels, and liver.

Groups of helminthes include (1) cestodes (tapeworms), (2) trematodes (flukes), (3) intestinal nematodes (roundworms), and (4) tissue-invading nematodes (tissue roundworms and filariae). They enter the human host via contaminated food, bites of carrier insects, or direct penetration of the skin. The cestodes (tapeworms) are segmented and enter the intestine via contaminated food. There are four species of cestodes: *Taenia solium* (pork tapeworm), *Taenia saginata* (beef tapeworm), *Diphyllobothrium latum* (fish tapeworm), and *Hymenolepis nana* (dwarf tapeworm). The segmented cestodes have heads and hooks or suckers that attach to the tissue.

The trematodes (flukes) are flat, nonsegmented parasites that feed on the host. Four types of trematodes exist: *Fasciola hepatica* (liver fluke), *Fasciolopsis buski* (intestinal fluke), *Paragonimus westermani* (lung fluke), and *Schistosoma species* (blood fluke).

Five types of nematodes may feed on intestinal tissue: *Ascaris lumbricoides* (giant roundworm), *Necator americanus* (hookworm), *Enterobius vermicularis* (pinworm), *Strongyloides stercoralis* (threadworm), and *Trichuris trichiura* (whipworm).

Two types of nematodes are tissue-invading: *Trichinella spiralis* (pork roundworm) and *Wuchereria bancrofti* (filariae). The pork roundworm, or *T. spiralis*, can cause **trichinosis** (disease caused by ingestion of raw or inadequately cooked pork that contains larvae of the *T. spiralis* parasite), which can be diagnosed by muscle biopsy. By thoroughly cooking pork, the roundworm, if present, is destroyed.

Side Effects and Adverse Reactions

The common side effects of **anthelmintics** (agents that destroy worms) include GI distress, which may manifest as anorexia, nausea, vomiting, and occasionally diarrhea and stomach cramps. The neurologic problems associated with anthelmintics are dizziness, weakness, headache, and drowsiness. Adverse reactions do not occur frequently, because the drugs usually are given for a short period (1 to 3 days), with the following exception: thiabendazole for treatment of threadworms and pork worms. Thiabendazole should be avoided if the patient has liver disease.

Table 33-3 lists eight anthelmintic drugs prescribed to treat various types of parasitic worms.

Nursing Process
Patient-Centered Collaborative Care

Anthelmintics

Assessment

- Obtain a history of foods patient has eaten, especially meat and fish, and how food was prepared.

TABLE 33-3 ANTHELMINTIC DRUGS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
bithionol (Bitin, Lorothidol))	A: PO: 30-50 mg/kg in 2 daily doses given every other day with food for 10-15 doses	Effective against flukes. For *Paragonimus* or *Fasciola* species when patient cannot receive praziquantel due to resistance or adverse effect.
diethylcarbamazine (Hetrazan)	A/C >15 kg: PO: 6 mg/kg, single dose	For treatment of tropical pulmonary eosinophilia or loiasis. Only available from CDC as investigational drug.
ivermectin (Stromectol)	A/C >15 kg: PO: 150-200 mcg/kg, single dose	Broad-spectrum antiparasitic drug. Causes paralysis to the parasite. Highly active against various mites. Pregnancy category: C; PB: UK; t½: 16-28 h
praziquantel (Biltricide)	A/C >4 y: PO: 20-25 mg/kg t.i.d. × 1-2 d	For beef, pork, and fish tapeworms; blood flukes; and liver, lung, and intestinal flukes. Pregnancy category: B; PB: 80%-85%; t½: 0.8-1.5 h
pyrantel pamoate (Pin-X)	A/C >2 y: PO: 10 mg/kg, single dose; *max:* 1 g	For giant roundworm, hookworm, and pinworm. Pregnancy category: C; PB: UK; t½: UK

A, Adult; *b.i.d.,* two times a day; *C,* child; *d,* day; *h,* hour; *max,* maximum; *PB,* protein-binding; *PO,* by mouth; *PRN,* as needed; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week; *y,* year; *>,* greater than; *<,* less than.

- Note if any other person in the household has been checked for helminths (worms).
- Assess patient for anal itching.
- Assess baseline vital signs, and collect a stool specimen.

Nursing Diagnoses

- Defensive coping related to invasion of helminth
- Activity intolerance related to dizziness, headache, drowsiness
- Disturbed body image related to fear of rejection by others
- Deficient knowledge related to inexperience with anthelmintic regime

Planning

- Patient will be free of helminths.
- Patient will explain how to prepare foods properly to avoid recurrence.
- Patient will describe methods of infection control.

Nursing Interventions

- Collect stool specimen in a clean container. Avoid having stool come in contact with water, urine, or chemicals, which could destroy parasitic worms.
- Administer prescribed anthelmintics after meals to prevent or minimize occurrence of GI distress.
- Report to health care provider if patient has any side effects.

Patient Teaching

- Explain to patient the importance of washing hands before eating and after going to the toilet. The parasite can be transferred within the family if proper hygiene is not used.
- Advise patient to take daily showers and not baths.
- Encourage patient to change sheets, bedclothes, towels, and underwear daily.
- Advise patient that a second course of anthelmintics may be necessary if helminthiasis persists after therapy.
- Emphasize importance of taking prescribed drug at designated times and keeping health care appointments.
- Teach patient to read all directions regarding over-the-counter drugs before use.
- Warn patient that drowsiness may occur, and operating a car or machinery should be avoided if this should happen.
- Teach patient to report any side effects/adverse reactions to health care provider.

Cultural Considerations

- Obtain an interpreter when necessary; do not rely on family members, who may not fully disclose because of honor or shame or because of lack of understanding of medical terminology.

Evaluation

- Evaluate effectiveness of anthelmintic therapy and absence of side effects.
- Determine if patient is using proper hygiene to avoid spread of parasitic worms.
- Evaluate patient's knowledge of preventative measures for helminthiasis.

Information on malaria: *www.cdc.gov/malaria*

CRITICAL THINKING CASE STUDY

TP, a 75-year-old woman, has shingles. She complains of pain and blisters (vesicular eruptions), which partially surround her waist. The health care provider prescribed acyclovir, 800 mg, every 4 hours, five times a day for 7 days.

1. When taking the health history, what should the nurse ask TP?
2. How does herpes zoster differ from varicella-zoster virus (VZV)? Explain who would be more susceptible to contracting herpes zoster virus infection.
3. How is acyclovir effective for relieving TP's symptoms?
4. Is the prescribed acyclovir dose correct? Explain your answer.
5. How does acyclovir differ from famciclovir and amantadine?
6. What comfort measures should the nurse suggest to TP?
7. What should the nurse teach TP about being around other people?

NCLEX STUDY QUESTIONS

1. A patient is diagnosed with HSV-3. The nurse understands that this illness is better known by which name? (Select all that apply.)
    - **a.** Chickenpox
    - **b.** Hepatitis B
    - **c.** Shingles in an adult
    - **d.** Cytomegalovirus
2. Zanamivir (Relenza) is ordered for a patient. What does the nurse know about use of this drug?
    - **a.** Treatment of HSV-2
    - **b.** Oral administration for treatment of HSV-1
    - **c.** Treatment of varicella-zoster viruses
    - **d.** Administration within 48 hours of onset of symptoms to be effective
3. A patient who is taking acyclovir asks the nurse about the drug. Which instruction should the nurse include in patient teaching?
    - **a.** Restrict fluids to prevent complications.
    - **b.** Monitor blood pressure for hypertension.
    - **c.** Stevens-Johnson syndrome is an adverse effect.
    - **d.** Blood tests are important for checking kidney function.
4. A patient with a history of malaria, presently being treated with chloroquine, is admitted to the hospital. What should the nurse advise the patient to do?
    - **a.** Get frequent hearing checks.
    - **b.** Take antimalarials before meals.
    - **c.** Get frequent testing of stool specimens.
    - **d.** Check heart rate before taking medication.
5. A patient is taking thiabendazole for trichinosis. What does the nurse realize about this condition and its treatment?
    - **a.** The medication is given for 7 days.
    - **b.** The medication should be avoided if the patient has renal disease.
    - **c.** Family members should be checked for the same disease.
    - **d.** Proper hygiene must be taught to avoid the spread of disease.
6. Acyclovir (Zovirax) has been ordered for a patient with genital herpes. Which nursing interventions are appropriate for this patient? (Select all that apply.)
    - **a.** Monitor patient's BUN and creatinine.
    - **b.** Monitor patient's BP for hypertension.
    - **c.** Administer IV acyclovir over 30 minutes.
    - **d.** Advise patient to maintain adequate fluid intake.
    - **e.** Teach patient to perform oral hygiene several times a day.
    - **f.** Monitor patient's CBC for blood dyscrasias.

OBJECTIVES

- Compare the groups of drugs that are urinary antiseptics and antiinfectives.
- Describe the side effects and adverse reactions to urinary antiseptics and antiinfectives.
- Differentiate the uses for a urinary analgesic, a urinary stimulant, and a urinary antispasmodic.
- Apply the nursing process, including teaching, to nursing care of the patient receiving urinary antiseptic/antiinfective drugs.

OUTLINE

Urinary Antiseptics/Antiinfectives and Antibiotics
  Nitrofurantoin
  Nursing Process: Patient-Centered Collaborative Care: Urinary Antiinfective:
  Nitrofurantoin
  Methenamine
  Trimethoprim and Trimethoprim-Sulfamethoxazole
  Fluoroquinolones (Quinolones)
  Drug-Drug Interactions
Urinary Analgesics
  Phenazopyridine
Urinary Stimulants
Urinary Antispasmodics/Antimuscarinics

micturition, p. 463
urinary analgesic, p. 460
urinary antiseptics/antiinfectives, p. 460
urinary stimulant, p. 460
urinary tract infection, p. 460

The largest number of urinary tract disorders are caused by **urinary tract infections** (UTIs), microbial infections of any part of the urinary tract. UTIs may result from an upper UTI, such as pyelonephritis, or a lower UTI, such as cystitis, urethritis, or prostatitis. A group of drugs called **urinary antiseptics/antiinfectives** prevents bacterial growth in the kidneys and bladder, but is not effective for systemic infections. Urinary antiseptics/antiinfectives have a **bacteriostatic** (inhibit bacterial growth) effect when given in lower dosages. They also have a **bactericidal** (kill bacteria) effect when given in higher dosages.

Urinary antiseptics/antiinfectives, **urinary analgesics** (relieve pain and burning in the urinary tract), **urinary stimulants** (agents that increase muscle tone of urinary muscles), and urinary antispasmodics/antimuscarinics are presented in this chapter. Chapters 29, 30, and 31 present further discussions of antibiotics, fluoroquinolones, and sulfonamides used to treat UTIs. Diuretics are discussed in Chapter 43.

Acute cystitis, a lower UTI, frequently occurs in female patients because of their shorter urethra. It is more common in women of childbearing age, older women, and young girls. Acute cystitis is commonly caused by *Escherichia coli.* Other bacterial causes include the gram-positive *Staphylococcus saprophyticus* and gram-negative *Klebsiella, Proteus,* and *Pseudomonas.* Symptoms of cystitis include pain and burning on urination and urinary frequency and urgency. A urine culture is usually obtained before the start of any antiinfective/antibiotic drug therapy. In male patients, a lower UTI is most likely prostatitis with symptoms similar to cystitis.

Acute pyelonephritis, an upper UTI, is commonly seen in women of childbearing age, older women, and young girls. *E. coli* is the most common organism causing pyelonephritis. Symptoms include chills, high fever, flank pain, pain during urination, urinary frequency and urgency, and pyuria. The bacterial count in the urine is greater than 100,000 bacteria/mL. In severe cases, the patient may be hospitalized and receive intravenous (IV) antibiotics (e.g., an aminoglycoside, ticarcillin/clavulanic acid, or piperacillin/tazobactam).

The most commonly used agents for treating UTIs are nitrofurantoin (Macrodantin); trimethoprim-sulfamethoxazole (Bactrim, Septra); and fluoroquinolones such as nalidixic acid (NegGram), norfloxacin (Noroxin), and ciprofloxacin (Cipro). Treatment may consist of a single double-strength dose of the chosen drug, a 3-day course, or the traditional method of 7 to 14 days of drug dosing. Fosfomycin tromethamine (Monurol), a nitrofurantoin prototype drug, is effective for UTIs as a single-dose treatment. Other agents used to treat UTIs include oral amoxicillin/clavulanic acid (Augmentin) and oral third-generation cephalosporins (cefixime, cefpodoxime proxetil, or ceftibuten). With severe UTIs, IV drug therapy followed by oral drug therapy is usually recommended.

URINARY ANTISEPTICS/ANTIINFECTIVES AND ANTIBIOTICS

Urinary antiseptics/antiinfectives are limited to the treatment of UTIs. Drug action occurs in the renal tubule and bladder, where it is effective in reducing bacterial growth. A urinalysis, as well as a culture and sensitivity test, is usually performed before the initiation of drug therapy. The groups of urinary antiseptics/antiinfectives are nitrofurantoin, methenamine, trimethoprim, and the fluoroquinolones.

Nitrofurantoin

Nitrofurantoin (Macrodantin) was first prescribed to treat UTIs in 1953. Nitrofurantoin is bacteriostatic or bactericidal, depending on the drug dosage, and is effective against many gram-positive and gram-negative organisms, especially *E. coli.* It is used to treat acute and chronic UTIs. The drug data for nitrofurantoin are given in Prototype Drug Chart 34-1.

Pharmacokinetics Nitrofurantoin is well absorbed from the gastrointestinal (GI) tract. The drug is usually taken with food to decrease GI distress. Decreased absorption occurs when the drug is taken with

PROTOTYPE DRUG CHART 34-1

Nitrofurantoin

Drug Class Urinary antiinfective Trade Names: Macrodantin Pregnancy Category: B	**Dosage** A: PO: 50-100 mg q.i.d. (with meals and h.s.); take with food; *max:* 7 mg/kg/d C >1 mo: PO: 1.25-1.75 mg/kg/d q6h; *max:* 7 mg/kg/d
Contraindications Hypersensitivity, moderate to severe renal impairment, oliguria, anuria, infants <1 mo, term pregnancy, lactation with infant suspected of having G-6-PD deficiency Caution: Vitamin B deficiency, electrolyte imbalance, diabetes mellitus	**Drug-Lab-Food Interactions** Drug: Decreased renal clearance with probenecid leading to toxicity; decreased absorption with antacids; decreased effectiveness of fluoroquinolones; decreased effectiveness of oral contraceptives
Pharmacokinetics Absorption: Well absorbed from GI tract; enhanced with food Distribution: PB: 20%-60%, crosses placenta, excreted in breast milk Metabolism: t½: 20 min Excretion: In urine; small amounts in bile	**Pharmacodynamics** PO: Onset: UK Peak: 30 min Duration: UK
Therapeutic Effects/Uses To treat acute and chronic UTIs Mode of Action: Inhibits bacterial enzymes and metabolism, also inhibits bacterial cell wall formation	
Side Effects Anorexia, nausea, vomiting, abdominal pain, rust/brown discoloration of urine, diarrhea, rash, pruritus, chills, dizziness, headache, drowsiness, confusion, depression, alopecia, nystagmus	**Adverse Reactions** Superinfection, angioedema, peripheral neuropathy, hemolytic anemia, aplastic anemia, thrombocytopenia, agranulocytosis Life-threatening: Anaphylaxis, hepatotoxicity, Stevens-Johnson syndrome

A, Adult; *C,* child; *CLcr,* creatinine clearance; *G-6-PD,* glucose-6-phosphate dehydrogenase; *GI,* gastrointestinal; *h.s.,* at bedtime; *min,* minute; *mo,* month; *PB,* protein-binding; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *UK,* unknown; *UTI,* urinary tract infection; *y,* year; <, less than.

antacids. Nitrofurantoin is moderately protein-bound. With normal renal function, the drug is rapidly eliminated because of its short half-life of 20 minutes; however, it accumulates in the serum with urinary dysfunction.

Pharmacodynamics When nitrofurantoin is given in low doses for prophylactic use, the drug has a bacteriostatic effect. High concentration of nitrofurantoin causes a bactericidal effect. Nitrofurantoin is effective against many gram-positive and gram-negative organisms such as *E. coli, Neisseria, streptococci, Staphylococcus aureus,* and others. It is not as effective against *Pseudomonas aeruginosa, Proteus species,* and some species of *Klebsiella.* The onset and duration of action are unknown. Peak action occurs 30 minutes after absorption. If sudden onset of dyspnea, chest pain, cough, fever, and chills develops, the patient should contact the health care provider. Symptoms resolve after discontinuing the drug.

The nursing process for nitrofurantoin is applicable to the other urinary antiseptics/antiinfectives.

Methenamine

Methenamine (Hiprex) produces a bactericidal effect when the urine pH is less than 5.5. Methenamine is available as hippurate salt. It is effective against gram-positive and gram-negative organisms, especially *E. coli* and *P. aeruginosa.* It is used for chronic UTIs. Methenamine should not be taken with sulfonamides, because crystalluria is likely to occur. It is absorbed readily from the GI tract, and approximately 90% of the drug is excreted in the urine unchanged. Methenamine forms ammonia and formaldehyde in acid urine; therefore the urine needs to be acidified to exert a bactericidal action. Cranberry juice (several 8-ounce glasses per day), ascorbic acid, and ammonium chloride can be taken to decrease the urine pH.

Nursing Process
Patient-Centered Collaborative Care

Urinary Antiinfective: Nitrofurantoin

Assessment

- Obtain a history from patient of clinical problems with UTI, incontinence, or other urinary tract disorders.
- Assess patient for signs and symptoms of UTI: pain or burning sensation on urination, frequency and urgency of urination.
- Monitor complete blood count (CBC) on patients with long-term therapy; monitor regularly.
- Monitor urine culture and sensitivity results.
- Assess renal and hepatic function.
- Determine urine pH. A pH of 5.5 is desired. However, alkalinization of the urine is not recommended.

Nursing Diagnoses

- Acute pain related to inflammation in the urinary tract
- Risk for infection related to insufficient knowledge to avoid invasion of pathogens

Planning

- Patient will be free of signs and symptoms of UTI within 10 days.

Nursing Interventions

- Monitor patient's urinary output and urine specific gravity. Careful attention to output is required when administering urinary antiseptics to patients with anuria and oliguria. Report promptly any decrease in urine output.
- Obtain urine culture to identify infecting organism before initiation of drug therapy to treat UTI.
- Observe patient for side effects and adverse reactions to urinary antiseptic drugs. Peripheral neuropathy (tingling, numbness of extremities) may result from renal insufficiency (inability to excrete drug) or long-term use of nitrofurantoin. Peripheral neuropathy may be irreversible.

Patient Teaching

General

- Teach patient not to crush tablets or open capsules.
- Advise patient to rinse mouth thoroughly after taking oral nitrofurantoin. Drug can stain teeth.
- Encourage patient to avoid antacids because they interfere with drug absorption.
- Teach patient to shake suspension well before administration and protect from freezing.
- Warn patient not to drive a motor vehicle or operate dangerous machinery; drug may cause drowsiness.
- Advise female patient to immediately report pregnancy to health care provider.

Diet

- Inform patient to increase fluids and take drug with food to minimize GI upset.

Side Effects

- Alert patient that urine may turn a harmless brown color.
- Encourage patient to report any signs of secondary fungal or bacterial infection (superinfection), such as stomatitis or anogenital discharge or itching.

Methenamine

- Educate patient to drink cranberry juice, eat plums, or take vitamin C (with approval of health care provider) to keep urine acidic. Foods that are alkaline, such as milk and some vegetables, may increase urine pH. Urine pH should be less than 5.5 for the antiseptic to be effective.

Fluoroquinolones

- Warn patient to avoid operating hazardous machinery or driving a car while taking drug, especially if dizziness is present.

- Encourage patient to take drug with food and avoid antacids, because they interfere with drug absorption.
- Alert patient that drug may turn urine a harmless brown color.
- Direct patient to report any signs of superinfection or secondary fungal or bacterial infection.
- Tell patient to avoid excessive exposure to sunlight.

Cultural Considerations

- Alleviate fear or concerns of patient from a different cultural background. Use culturally consistent communication when explaining the treatment regimen for a UTI. An interpreter may be necessary. The use of pamphlets in the language patient reads or speaks most easily can facilitate patient understanding.

Evaluation

- Evaluate the effectiveness of the urinary antiinfectives in alleviating the UTI. Patient is free of side effects and adverse reactions to drug.

Trimethoprim and Trimethoprim-Sulfamethoxazole

Trimethoprim (Proloprim) can be used alone for the treatment of UTIs, although it is usually used in combination with a sulfonamide, sulfamethoxazole (the combined preparation is generically called *TMP/SMZ*), to prevent the occurrence of trimethoprim-resistant organisms. This drug combination produces slow-acting bactericidal effects against most gram-positive and gram-negative organisms. TMP/SMZ (Bactrim, Septra) is discussed in Chapter 31. Trimethoprim is used in the treatment and prevention of acute and chronic UTIs. The amount of trimethoprim in the prostatic fluid is about two to three times greater than the amount in the vascular fluid. The half-life of trimethoprim is normally 8 to 11 hours, but it is longer in patients with renal dysfunction.

Fluoroquinolones (Quinolones)

Fluoroquinolones are one of the groups of urinary antibacterials that are effective against lower UTIs; they include nalidixic acid (NegGram), norfloxacin (Noroxin), ciprofloxacin hydrochloride (Cipro), and ofloxacin . , Norfloxacin, ciprofloxacin, and ofloxacin, are effective against a wide variety of UTIs. The drug dosage must be decreased when renal dysfunction is present. The half-lives of these drugs are ordinarily 2 to 8 hours, but are prolonged in patients with renal dysfunction. Table 34-1 lists the urinary antiseptics/antiinfectives and their dosages, uses, and considerations.

Side Effects and Adverse Reactions

Nitrofurantoin. Side effects of nitrofurantoin use include (1) GI disturbances such as anorexia, nausea, vomiting, diarrhea, and abdominal pain and (2) pulmonary reactions such as dyspnea, chest pain, fever, and cough.

Methenamine. Methenamine use has GI side effects, including nausea, vomiting, and diarrhea. Allergic reactions to the dye in Hiprex have occurred. Bladder irritation and crystalluria (when taken in large doses) may occur.

Trimethoprim. GI symptoms (including nausea and vomiting) and skin problems (including rash and pruritus) can accompany trimethoprim use.

Fluoroquinolones. Nalidixic acid use can have the following side effects: headaches, dizziness, syncope (fainting), peripheral neuritis, visual disturbances, and rash. Nausea, vomiting, diarrhea, headaches, and visual disturbances can occur with cinoxacin and norfloxacin use. Photosensitivity is a common side effect associated with fluoroquinolones.

Drug-Drug Interactions

The following drug-drug interactions can occur with the use of urinary antiseptics/antiinfectives:

- Antacids decrease nitrofurantoin absorption.
- Sodium bicarbonate inhibits the action of methenamine.
- Methenamine mandelate taken with sulfonamides increases the risk of crystalluria.
- Nalidixic acid enhances the effects of warfarin (Coumadin).
- Most urinary antiseptics cause false-positive Clinitest results.

URINARY ANALGESICS

Phenazopyridine

Phenazopyridine hydrochloride (Pyridium), an azo dye, is a urinary analgesic (relieves urinary pain and burning) that has been available for almost 40 years. It is used to relieve the pain, burning sensation, and frequency and urgency of urination that are symptomatic of lower UTIs. The drug can cause GI disturbances, hemolytic anemia, nephrotoxicity, and hepatotoxicity. The urine becomes a harmless reddish orange because of the dye. Phenazopyridine can alter the glucose urine test (Clinitest); therefore, a blood test should be used to monitor glucose levels.

URINARY STIMULANTS

When bladder function is decreased or lost as a result of (1) a neurogenic bladder (a dysfunction caused by a lesion of the nervous system), (2) a spinal cord injury (paraplegia, hemiplegia), or (3) a severe head injury, a parasympathomimetic may be used to stimulate **micturition** (urination). The drug of choice, bethanechol chloride (Urecholine), is a urinary stimulant, also known as a *direct-acting parasympathomimetic* (cholinomimetic). The drug action is to increase bladder tone by increasing tone of the detrusor urinal muscle, which produces a contraction strong enough to stimulate urination. Bethanechol is discussed in detail in Chapter 19.

TABLE 34-1 ANTISEPTICS AND URINARY ANTIINFECTIVES

GENERIC (TRADE) NAME	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
fosfomycin tromethamine (Monurol)	A: PO: 3-g packet dissolved in 4 oz water, as a single dose	For uncomplicated UTIs in women. Has a bactericidal effect against most gram-negative and gram-positive bacteria. Side effects include headaches and diarrhea. Pregnancy category: B; PB: 0%; t½: 3-8.5 h
methenamine hippurate (Hiprex, Urex)	Hippurate: A: PO: 1 g b.i.d. C 6-12 y: PO: 0.5-1 g q12h	For chronic UTIs. Urine pH should be acidic (<5.5). Do not use with sulfonamides. May cause crystalluria, so push fluids. May cause GI irritation, so give with meals. Pregnancy category: C; PB: UK; t½: 4 h
nitrofurantoin (Macrodantin)	See Prototype Drug Chart 34-1.	
trimethoprim (Proloprim)	A: PO: 100 mg b.i.d. or 200 mg/d for 10-14 d	For prevention and treatment of acute and chronic UTIs in both men and women. High doses can cause GI upset. Drug can be combined with sulfamethoxazole (Bactrim). Pregnancy category: C; PB: 45%; t½: 8-10 h
ertapenem (Invanz)	A/Adol: IM/IV: 1 g/d for 10-14 d C >3 mo: IM/IV: 15 mg/kg b.i.d. for 10-14 d	To prevent recurring UTIs, acute pelvic infections, and diabetic foot infections. Effective against gram-positive and gram-negative bacteria. Commonly causes diarrhea, nausea, and headache. Pregnancy category: B; PB: 95%; t½: 4.5 h
Sulfonamides		
trimethoprim-sulfamethoxazole (TMP-SMZ, Bactrim, Septra)	See Prototype Drug Chart 31-1 in Chapter 31.	Effective for serious UTIs and otitis media. Pregnancy category: C; PB: 44%-70%; t½: 6-12 h
Quinolones (Fluoroquinolones)		
ciprofloxacin (Cipro)	A: PO: Mild to moderate: 250 mg q12h for 3 d A: PO: ER: 500 mg/d for 3 d A: IV: 200 q12h A: PO: severe/complicated: 500 mg q12h for 7-14 d; 1 g/d XRfor 7-14 d C: PO: 10-20 mg/kg q12h for 10-21 d A: IV: 400 mg q12h for 7-14 d; dilute and infuse over 1 h C: IV: 6-10 mg/kg q8h for 10-21 d	Has broad-spectrum antibacterial effect. For UTI, skin and soft-tissue infections, bone and joint infections, and anthrax infection. Antacid inhibits drug absorption. Use with caution in patients with seizure disorders. Can be taken without food. Photosensitivity can occur. Avoid excessive exposure to sunlight. Pregnancy category: C; PB: 20%-40%; t½: 4 h
nalidixic acid (NegGram)	A: PO: 1 g q.i.d. for 1-2 wk; 500 mg q.i.d. for long-term use; *max:* 4 g/d C >3 mo: PO: 55 mg/kg/d in 4 divided doses for 1-2 wk; 33 mg/kg/d for long-term use	For acute and chronic UTIs. Resistance to drug may occur. Highly protein-bound. Not distributed in prostatic fluid. Give with food to avoid GI upset. Photosensitivity can occur. Have patient contact health care provider if seizures or severe headaches occur. Pregnancy category: C; PB: 93%; t½: 1-2.5 h
norfloxacin (Noroxin)	A: PO: 400 mg q12h for 3-21 d on empty stomach	For acute and chronic UTIs. Most potent drug of the quinolone group. Food may inhibit drug absorption. Pregnancy category: C; PB: 10%-15%; t½: 3-4 h
ofloxacin	A: PO: 200 mg q12h for 3-10 d	For UTIs, respiratory tract infections, and skin infections. May cause headaches, dizziness, and insomnia. Pregnancy category: C; PB: UK; t½: 4-8 h
Other		
aztreonam (Azactam)	A: IM/IV: 500 mg–1 g q8-12h C >9 mo: IM/IV: 30 mg/kg q6-8h	Treatment of UTIs caused by gram-negative organisms. Also useful for lower respiratory tract infections and septicemia. Pregnancy category: B; PB: 56%-60%; t½: 1.5-2 h
imipenem/cilastatin sodium (Primaxin)	A: IV: 250 mg q6-8h; *max:* 4 g/d or 50 mg/kg/d, whichever is less	Treatment of serious UTIs. Also useful for lower respiratory tract, bone, and joint infections; septicemia; and endocarditis. Pregnancy category: C; PB: imipenem 20%/cilastatin 40%; t½: 1 h
polymyxin B SO_4	A/C: IV: 15,000-25,000 units/kg/d in divided doses q12h	Effective for UTIs and prevention of bacteruria from Foley catheter. Can cause nephrotoxicity. Monitor renal function (BUN, serum creatinine). Pregnancy category: B; PB: UK; t½: 4-6 h

A, Adult; *Adol,* adolescent; *b.i.d.,* twice a day; *BUN,* blood urea nitrogen; *C,* child; *CLcr,* creatinine clearance; *d,* day; *ER,* extended-release; *GI,* gastrointestinal; *h,* hour; *IM,* intramuscular; *IV,* intravenous; *min,* minute; *mo,* month; *PB,* protein-binding; *p.c.,* after meals; *PO,* by mouth; *q.i.d.,* four times a day; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *UTI,* urinary tract infection; *wk,* week; *y,* year; *>,* greater than; *<,* less than.

URINARY ANTISPASMODICS/ ANTIMUSCARINICS

Urinary tract spasms resulting from infection or injury can be relieved with **antispasmodics** that have a direct action on the smooth muscles of the urinary tract. This group of drugs (dimethyl sulfoxide [also called *DMSO*], oxybutynin [Ditropan], and flavoxate [Urispas]) is contraindicated for use if urinary or GI obstruction is present or if the patient has glaucoma. Antispasmodics have the same effects as **antimuscarinics** (agents that block parasympathetic nerve impulses), parasympatholytics, and anticholinergics (see Chapter 19). Side effects include dry mouth, increased heart rate, dizziness, intestinal distention, and constipation. Tolterodine tartrate (Detrol) is an antimuscarinic/anticholinergic drug used to control an overactive bladder, which causes frequency in urination. This drug also decreases urge urinary incontinence. It has the same side effects as antispasmodics/anticholinergics. The patient taking antimuscarinic/anticholinergic drugs should be taught to report urinary retention, severe dizziness, blurred vision, palpitations, and confusion. The patient should be warned to use caution in hot environments to avoid heat prostration. Table 34-2 lists drugs that are urinary analgesics, stimulants, and antispasmodics/antimuscarinics.

TABLE 34-2 URINARY ANALGESICS, STIMULANTS, AND ANTISPASMODICS

GENERIC (BRAND)	ROUTE AND DOSAGE	USES AND CONSIDERATIONS
Urinary Analgesics		
phenazopyridine HCl (Pyridium)	A: PO: 200 mg t.i.d. p.c.; *max:* 600 mg/d	For chronic cystitis to alleviate pain and burning sensation during urination. Urine will be reddish orange. Can be taken concurrently with an antibiotic. Treats only symptoms, not underlying cause. Do not use long-term for undiagnosed urinary tract pain. Pregnancy category: B; PB: UK; t½: UK
Urinary Stimulants		
bethanechol Cl (Urecholine)	A: PO: 10-50 mg t.i.d./q.i.d. 1 h a.c. or 2 h p.c.; *max:* 200 mg/d A: subQ: 5-mg single dose, may repeat 3-4 times PRN; *max:* 40 mg/d	For hypotonic or atonic bladder. Do not take if peptic ulcer is present. Can cause epigastric distress, abdominal cramps, nausea, vomiting, diarrhea, and flatulence. Can cause dizziness, lightheadedness, and fainting, especially when standing up from lying or sitting position. Pregnancy category: C; PB: UK; t½: UK
Urinary Antispasmodics		
dimethyl sulfoxide (DMSO, Rimso-50)	Bladder instillation: 50 mL of 50% sol retained for 15 min; repeat q2wk until relief	For cystitis. Administered into the bladder to remain for 15 minutes. Additional effects are antiinflammatory, anesthetic, and bacteriostatic. Can cause garlic-like taste and odor on breath and skin for up to 72 h. Pregnancy category: C; PB: UK; t½: UK
flavoxate HCl (Urispas)	A: PO: 100-200 mg t.i.d./q.i.d.	For urinary tract spasms. Avoid in patients with glaucoma. Cautious use by older adults. Side effects include nausea, vomiting, dry mouth, drowsiness, blurred vision. Pregnancy category: B; PB: 50%-80%; t½: 10-20 h
oxybutynin Cl (Ditropan)	A: PO: 5 mg b.i.d./t.i.d.; *max:* 20 mg/d Older adults: PO: 2.5-5 mg b.i.d.; *max:* 20 mg/d C >5 y: PO: 5 mg b.i.d.; *max:* 15 mg/d	For urinary tract spasms and overactive bladder. Contraindicated for patients with cardiac, renal, hepatic, and prostate problems. Side effects include drowsiness, blurred vision, and dry mouth. Pregnancy category: B; PB: UK; t½: 2-5 h
mirabegron (Myrbetriq)	A:PO: 25 mg qd	For treatment of overactive bladder. Pregnancy category: C; PB: 71%; t½: 50 h
Antimuscarinics/Anticholinergics		
tolterodine tartrate (Detrol, Detrol LA)	A: PO: 2 mg b.i.d.; *max*: 4 mg/d A: ER: 4 mg/d	To control overactive bladder by decreasing urinary frequency and urgency. Patients with narrow-angle glaucoma should not take this drug. Dry mouth is common. Pregnancy category: C; PB: 96%; t½: 2-4 h
trospium chloride (Sanctura, Sanctura XR)	A: PO: 20 mg b.i.d.; *max:* 60 mg/d A: ER: 60 mg/d in morning	To treat overactive bladder by action of a muscarinic-receptor antagonist. Pregnancy category: C; PB: 50%-85%; t½: 20-35 h
solifenacin succinate (VESIcare)	A: PO: 5 mg/d initially; then up to 10 mg/d if tolerated; *max:* 10 mg/d	To treat overactive bladder by action of a muscarinic-receptor antagonist. Pregnancy category: C; PB: 98%; t½: 55 h
darifenacin hydrobromide (Enablex)	A: PO: 7.5-15 mg/d; *max:* 15 mg/d	To treat overactive bladder by action of a muscarinic-receptor antagonist. Pregnancy category: C; PB: 98%; t½: 13-19 h

A, Adult; *a.c.,* before meals; *b.i.d.,* twice a day; *C,* child; *d,* day; *ER,* extended-release; *h,* hour; *max,* maximum; *min,* minute; *PB,* protein-binding; *p.c.,* after meals; *PO,* by mouth; *PRN,* as needed; *q.i.d.,* four times a day; *subQ,* subcutaneous; *sol,* solution; *t½,* half-life; *t.i.d.,* three times a day; *UK,* unknown; *wk,* week; *XR,* extended release; *y,* year; *>,* greater than.

CRITICAL THINKING CASE STUDY

FL, a 29-year-old woman, has complained to her health care provider of painful urinary frequency and urgency. The patient has an elevated temperature. A urine specimen indicates that FL has a urinary tract infection (UTI). The health care provider prescribes co-trimoxazole D.S. tablets (double-strength, T-160 mg/S-800 mg) twice a day for 14 days.

1. What other information should the health care provider obtain from the patient?
2. What other dose of co-trimoxazole (TMP-SMZ) could be prescribed? Explain your answer.
3. What should the health care provider discuss with the patient in regard to taking the drug and its possible side effects? What other information should FL receive?
4. What is the recommended time for follow-up care for FL?
5. What other drugs might be used instead of co-trimoxazole? Would one urinary antiinfective drug be more effective than another antiinfective drug? Explain your answer.

NCLEX STUDY QUESTIONS

1. A patient is taking nitrofurantoin (Macrodantin). What will the nurse teach the patient?
   a. Expect the urine to turn blue.
   b. Keep the urine acidic by drinking milk.
   c. Rinse the mouth after taking oral nitrofurantoin to avoid teeth staining.
   d. Take an antacid with oral nitrofurantoin to avoid gastrointestinal distress.
2. A patient complains about a burning sensation and pain when urinating. Which urinary analgesic does the nurse suspect will be ordered?
   a. tolterodine (Detrol)
   b. oxybutynin (Ditropan)
   c. bethanechol (Urecholine)
   d. phenazopyridine (Pyridium)
3. A patient is taking the urinary antiseptic methenamine mandelate for a urinary tract infection. The nurse understands that this drug should not be given concurrently with which other drug to avoid potential crystalluria?
   a. ertapenem (Invanz)
   b. ciprofloxacin (Cipro)
   c. nalidixic acid (NegGram)
   d. trimethoprim-sulfamethoxazole (Bactrim)
4. A patient is receiving solifenacin succinate (VESIcare). The nurse knows that this drug is used to treat which condition?
   a. Chronic cystitis
   b. Urinary tract stones
   c. Urinary tract infection
   d. Overactive bladder
5. The patient is taking tolterodine tartrate (Detrol). The nurse plans to teach the patient to report which condition?
   a. Alkaline urine
   b. Urinary retention
   c. Excessive tearing
   d. Reddish orange urine
6. The nurse is caring for a patient who is taking nitrofurantoin (Macrodantin). Which nursing interventions are appropriate for this patient? (Select all that apply.)
   a. Monitor urinary output and urine specific gravity.
   b. Monitor the patient for peripheral neuropathy.
   c. Advise the patient to take the medication on an empty stomach to enhance absorption.
   d. Warn the patient to avoid excess exposure to sunlight.
   e. Inform the patient that urine may turn a harmless brown color.

Answers: 1, c; 2, d; 3, d; 4, d; 5, b; 6, a, b, e.

UNIT XI

Immunologic Agents

Immunity comprises functions that protect people from the effects of invasion of the body by microscopic organisms such as bacteria, viruses, molds, spores, pollens, protozoa, and cells from other persons or animals. A person remains in harmony with these organisms as long as the organisms do not enter the body's internal environment. The body has various defenses (e.g., skin) that prevent microorganisms from gaining access to its internal environment. However, these defenses are not infallible, and invasion of the body's internal environment by microorganisms occurs often. A properly functioning immune system neutralizes, eliminates, or destroys the invading microorganisms. To do this without harming the body, immune system cells use defensive actions against only nonself proteins and cells. This means that immune system cells can differentiate between the body's own healthy self cells and other nonself proteins and cells.

Nonself proteins and cells include (1) all foreign cells and microorganisms, (2) infected or debilitated body cells, and (3) self cells that have undergone malignant transformation into cancer cells. This ability to recognize self versus nonself, which is necessary to prevent healthy body cells from being destroyed along with the invaders, is called *self-tolerance.* Immune system cells are the only body cells capable of recognizing self from nonself.

Unique proteins on the surface of all body cells of each individual serve as a personal identification code for that person. The cell-surface proteins of one person are recognized as "foreign" by the immune system of another person. These are antigens—proteins capable of stimulating an immune response.

Immune function is generally most efficient when people are in their twenties and thirties; it slowly declines with increasing age. Older adults have marginal immune function, causing increased susceptibility to a variety of pathologic conditions.

IMMUNE SYSTEM STRUCTURE

The immune system is not confined to any one organ or body area. Instead, immune system cells originate in the bone marrow. Some of these cells mature in the bone marrow; others leave the bone marrow and mature in different body sites. After maturation, most immune system cells are released into the blood, where they circulate throughout the body and exert specific effects.

IMMUNE SYSTEM FUNCTION

The three processes necessary for immunity together with the cells involved in these responses can be categorized as inflammation, antibody-mediated immunity (humoral immunity), and cell-mediated immunity. Inflammation is discussed in the introduction to Unit VII. Full immunity, or *immunocompetence,* requires the adequate function and interaction of all three processes, although some functions of each overlap. Long-lasting immune actions are those generated by antibody-mediated immunity and cell-mediated immunity.

Antibody-Mediated Immunity

Antibody-mediated immunity (AMI), also called *humoral immunity,* involves antigen-antibody interactions that neutralize, eliminate, or destroy foreign proteins. Antibodies for these interactions are produced by populations of B-lymphocytes.

Antigen-Antibody Interactions

Antigen-antibody interactions occur in the body's internal environment. To make an antibody that can exert its effects on a specific antigen, the body must first be exposed to that antigen to the degree that the antigen enters the body. Even when exposure includes penetration, not all exposures result in the stimulation of antibody production. Invasion by the antigen must occur in such large numbers that some of the antigen either evades detection by the normal nonspecific defenses or overwhelms the abilities of the inflammatory response to neutralize, eliminate, or destroy the invader.

Acquiring Antibody-Mediated Immunity

The two broad categories of immunity are *innate immunity* and *acquired immunity.* Innate immunity is a genetically determined characteristic of an individual, group, or species. A person either has or does not have innate immunity. For example, humans have many innate immunities to viruses and other microorganisms that cause specific diseases in animals. As a result, humans are not susceptible to such diseases as mange, distemper, hog cholera, or any of a variety of animal afflictions. This type of immunity cannot be developed or transferred from one person to another and is not an adaptive response to exposure or invasion by foreign proteins.

Acquired immunity is the immunity that every person's body makes (or can receive) as an adaptive response to invasion by foreign proteins. Antibody-mediated immunity is an acquired immunity. Acquired immunity occurs either naturally or artificially and can be either active or passive. Active immunity occurs when antigens enter the body and the body responds by making specific antibodies against the antigen. This type of immunity is active because the body takes an active part in making the antibodies. Active immunity can occur under conditions that are either natural or artificial. Natural active immunity occurs when an antigen enters the body without human assistance, and the body responds by actively making antibodies against that antigen (e.g., chickenpox virus). Most of the time, the first invasion of the body by this antigen results in the person manifesting signs and symptoms of the disease. However, processes occurring in the body at the same time allow the person to acquire immunity to that antigen so that a second exposure to the same antigen will not cause illness. This type of immunity is the most effective and the longest lasting.

Artificial active immunity is a type of protection developed against illnesses that produce such serious side effects that total avoidance of the disease is most desirable. Small amounts of specific antigens are deliberately placed in the body (as a vaccination) so that the body responds by actively making antibodies against the antigen. Because antigens used for this procedure have been specially processed to make them less likely to proliferate within the body, this exposure does not in itself cause the disease.

Examples of diseases for which artificially acquired active immunity can be obtained include tetanus, diphtheria, measles, smallpox, mumps, and rubella. This type of immunity lasts many years, although repeated but smaller doses of the original antigen are periodically required as a "booster" to maintain complete protection against the antigen.

Passive immunity occurs when antibodies against a specific antigen are in a person's body, but the person did not actively generate these antibodies. Instead, these antibodies are made in the body of another person or animal and then transferred to the body of a specific individual. Because these antibodies are foreign to the individual, the body recognizes the antibodies as nonself and takes steps to eliminate them relatively quickly. For this reason, passive immunity can provide only immediate, short-term protection against a specific antigen.

Cell-Mediated Immunity

Cell-mediated immunity (CMI), or cellular immunity, involves many leukocyte actions, reactions, and interactions that range from the simple to the complex. This type of immunity is provided by committed lymphocyte stem cells that mature in the secondary lymphoid tissues of the thymus and pericortical areas of lymph nodes. Certain CMI responses influence and regulate the activities of antibody-mediated immunity and inflammation by producing and releasing cytokines; therefore, total immunocompetence relies on optimal CMI function.

The leukocytes playing the most important roles in CMI include several specific T-lymphocyte subsets along with a special population of cells known as *natural killer cells* (NK cells). T-lymphocytes further differentiate into a variety of subsets, each of which has a specific function. The three T-lymphocyte subsets crucial to the development and continuation of CMI are helper/inducer T-cells, suppressor T-cells, and cytotoxic/cytolytic T-cells.

Protection Provided by Cell-Mediated Immunity

Specific components of CMI assist in providing protection to the body by their highly developed abilities to differentiate self from nonself. The nonself cells most easily recognized by CMI are self cells that are infected by organisms that live within host cells and self cells that are mutated at the DNA level and are thus abnormal. CMI provides a surveillance system that rids the body of self cells that might potentially harm the body. CMI is critically important in preventing development of cancer and metastasis after exposure to carcinogens.

CHAPTER

- Review Questions for the NCLEX® Examination
- References from the Textbook
- Unfolding Case Studies

OBJECTIVES

- Describe the life cycle of the human immunodeficiency virus (HIV), and relate it to the actions of pharmacologic agents used in the treatment of HIV disease.
- Identify the risk factors for HIV transmission.
- Describe the six classifications of antiretroviral therapy, and give examples of medications in each group.
- Explain specific issues of medication adherence to antiretroviral agents.
- Discuss the nurse's role in medication management and issues of adherence.
- Explain prophylactic treatment for opportunistic infections.
- Discuss the medical management for preventing mother-to-child transmission of HIV infection during pregnancy.
- Discuss health care workers' exposure risks, and relate the risk and type of exposure to recommendations.
- Apply the nursing process, including teaching, to the care of patients with HIV infection.

Acquired immunodeficiency syndrome (AIDS) was first reported in the United States in 1981 and has led to the death of more than 25 million people globally since 1981. In 2009, an estimated 1.8 million deaths occurred, including 260,000 children younger than 15 years. It is estimated that 33.3 million people worldwide were living with HIV in 2009. The annual number of new HIV infections was 2.6 million in 2009, a reduction from 3 million in 2001. In the United States, it is estimated that at the end of 2009, 1.5 million people were living with HIV/AIDS, and that 210,000 people are unaware that they are HIV infected.

Significant improvement in HIV-related morbidity and mortality and a reduction in perinatal and behaviorally associated HIV transmission have become possible with combination antiretroviral therapy. Attaining viral suppression of HIV necessitates the use of at least two and preferably three active drugs from two or more drug classes.

This is referred to as **highly active antiretroviral therapy** (HAART), **combination antiretroviral therapy** (cART), or **antiretroviral therapy** (ART). Patients who engage and are retained in HIV care and treatment can now experience HIV as a chronic illness rather than a disease of death and dying. In the United States, approximately 30% of people living with HIV/AIDS are age 50 years or older. Areas of concern in older HIV patients are as follows:

1. Older HIV-infected patients may have age-related comorbid illnesses that can complicate management of HIV infection.
2. HIV may affect the biology of aging, possibly causing premature aging.
3. Reduced mucosal and immunologic defenses (such as postmenopausal atrophic vaginitis) and behavioral changes (such as decreased condom use because of less concern about pregnancy and increased use of erectile dysfunction medication) could result in increased risk of HIV acquisition and transmission.
4. Health care providers generally perceive older adults to be at decreased risk for HIV and as a result do not screen this age group as frequently as others.

Although strides have been made in the treatment of HIV/AIDS, challenges remain. One important aspect is increased drug **resistance** to current therapies. The makeup of the HIV DNA strands allows the virus to mutate from a drug-sensitive to a drug-resistant form. The patient is encouraged to achieve >95% medication **adherence** to minimize medication resistance, but studies suggest that 6% to 16% of patients who are naïve to ART have pre-existing genotypic resistance.

Nursing and public health initiatives should incorporate harm-reduction education to further minimize transmission of resistant virus (e.g., safer sex, not sharing needles or drug works, needle exchange programs).

HIV INFECTION: PATHOPHYSIOLOGY

HIV is an RNA retrovirus. It is unable to survive and replicate unless it is inside a living human cell. HIV destroys CD4+ T cells (also called *helper T cells* or *CD4 + T lymphocytes*), which play a critical role in the human **immune response** through recognition of infectious and neoplastic processes. The destruction of CD4 cells by HIV results in immune deficiency. The CD4 cell count is an indicator for immune function in those with HIV.

Normal CD4 counts range from 800 to 1200 cells/mm^3. After initial infection, there is rapid viral replication, resulting in a high level of virus in peripheral blood (viral load). There is a corresponding drop in CD4 cells, which triggers an immune response, resulting in CD4 cell replacement and HIV antibody production. The viral load drops with establishment of immune response. Symptoms range from mild to severe (fever, fatigue, pharyngitis, myalgia or arthralgia, lymphadenopathy, headache, night sweats) in those recently infected with HIV and can be experienced 2 to 12 weeks after HIV exposure. This period is called *acute retroviral syndrome, acute seroconversion syndrome,* or *primary HIV infection.* Symptoms in this stage can often be mistaken by both patient and health care provider for a transient flulike illness. Consequently, few people are diagnosed during this time. Additionally, the time delay from infection to a positive HIV test result averages 10 to 14 days, but some do not seroconvert for 3 to 4 weeks. Almost all patients seroconvert within 6 months. This time delay between infection and positive test results is known as the *window period.* For this reason, patients who are at risk for HIV infection and test negative should be counseled to have the test repeated in 3 months (the close of the window period). If HIV is strongly suspected, an HIV RNA quantitative test can be done. A high viral load would support HIV diagnosis (>10,000 c/mL and usually >100,000 c/mL).

Over time and in the absence of treatment, HIV infection generally progresses slowly with a gradual decline in CD4 cells. AIDS is a diagnosis that indicates advanced disease. The 1993 AIDS surveillance case definition includes all patients with a CD4 count <200 cells/mm^3 or <14% of total lymphocytes, or one of the other AIDS-defining conditions listed in Table 35-1. The risk of opportunistic infection increases when CD4 counts fall below 200 cells/mm^3.

TABLE 35-1 **CLASSIFICATION SYSTEM FOR HIV INFECTION***

	CLINICAL CATEGORIES FOR ADULTS		
	(A) ASYMPTOMATIC, ACUTE (PRIMARY) HIV OR PERSISTENT GENERALIZED LYMPHADENOPATHY	(B) SYMPTOMATIC, NOT (A) OR (C) CONDITIONS	(C) AIDS-INDICATOR CONDITIONS
(1) ≥500/mcL	A1	B1	C1
(2) 200-499/mcL	A2	B2	C2
(3) <200/mcL	A3	B3	C3
AIDS-indicator T-cell count			

≥, Greater than or equal to; <, less than.

From the Department of Health and Human Services, Henry J. Kaiser Family Foundation: Panel on practices for treatment of HIV infection: guidelines for the use of antiretroviral agents in HIV-infected adults and adolescents, Dec 1, 1998.

*The revised CDC classification system for HIV-infected adolescents and adults categorizes persons on the basis of CD4 T-lymphocyte counts and clinical conditions associated with HIV infection. The system is based on three ranges of CD4 T-lymphocyte counts and three clinical categories (Categories A to C).

CD4 T-LYMPHOCYTE CATEGORIES

HIV-infected persons should be classified based on existing guidelines for the medical management of HIV-infected persons; thus, the lowest accurate CD4 T-lymphocyte count (but not necessarily the most recent) should be used for classification purposes.

Clinical Categories

Category A consists of one or more of the following conditions in an adolescent or adult (13 years of age or older) with documented HIV infection. Conditions listed in categories B and C must not have occurred.

- Asymptomatic HIV infection
- Persistent generalized lymphadenopathy
- Acute (primary) HIV infection with accompanying illness or history of acute HIV infection

Category B consists of symptomatic conditions in an HIV-infected adolescent or adult that are not included in category C and are attributed to HIV infection or are considered to have a clinical course complicated by HIV infection. Examples of conditions in category B include, but are not limited to, the following:

- Bacillary angiomatosis
- Candidiasis, oropharyngeal (thrush)
- Candidiasis, vulvovaginal; persistent, frequent, or poorly responsive to therapy
- Cervical dysplasia (moderate or severe)/cervical carcinoma in situ
- Constitutional symptoms, such as fever (101.3° F or 38.5° C) or diarrhea lasting longer than 1 month
- Hairy leukoplakia, oral
- Herpes zoster (shingles), involving at least two distinct episodes or more than one dermatome
- Idiopathic thrombocytopenic purpura
- Listeriosis
- Pelvic inflammatory disease, particularly if complicated by tubo-ovarian abscess
- Peripheral neuropathy

For classification purposes, category B conditions take precedence over category A conditions.

Category C includes the clinical conditions listed in the AIDS surveillance case definition. For classification purposes, once a category C condition occurs, the person remains in category C.

- Bacterial pneumonia, recurrent (two or more episodes in 12 months)
- Candidiasis of the bronchi, trachea, or lungs
- Candidiasis, esophageal
- Cervical carcinoma, invasive, confirmed by biopsy
- Coccidioidomycosis, disseminated or extrapulmonary
- Cryptococcosis, extrapulmonary
- Cryptosporidiosis, chronic intestinal
- Cytomegalovirus disease
- HIV-related encephalopathy
- Herpes simplex: chronic ulcers or bronchitis, pneumonitis, or esophagitis
- Histoplasmosis, disseminated or extrapulmonary
- Kaposi sarcoma
- Lymphoma, Burkitt, immunoblastic, or primary central nervous system
- *Mycobacterium avium* complex (MAC) or *M. kansasii,* disseminated or extrapulmonary
- Mycobacterium tuberculosis, pulmonary or extrapulmonary
- *Pneumocystis jiroveci* (formerly *carinii*) pneumonia (PCP)
- Progressive multifocal leukoencephalopathy (PML)
- Salmonella septicemia, recurrent

HIV LIFE CYCLE

The phases of the HIV life cycle (Figure 35-1) are (1) binding and fusion: HIV begins its life cycle when it binds to a CD4 receptor and one of two co-receptors on the surface of a CD4 T-lymphocyte. The virus then fuses with the host cell. After fusion, the virus releases RNA, its genetic material, into the host cell; (2) reverse transcription: An HIV enzyme called **reverse transcriptase** (RT) converts the single-stranded HIV RNA to a double-stranded HIV DNA; (3) integration: The newly formed HIV DNA enters the host cell's nucleus, where an HIV enzyme called **integrase** "hides" the HIV DNA within the host cell's own DNA. The integrated HIV DNA is called a provirus; (4) transcription: When the host cell receives a signal to become active, the provirus uses a host enzyme called RNA polymerase to create copies of the HIV genomic material, as well as shorter strands of RNA called messenger RNA (MRNA). The mRNA is used as a blueprint to make long chains of HIV proteins; (5) **assembly:** An HIV enzyme called **protease** cuts the long chains of HIV proteins into smaller individual proteins. As the smaller HIV proteins come together with copies of HIV's RNA genetic material, a new virus particle is assembled; (6) **budding:** The newly assembled virus pushes out ("buds") from the host cell. During budding, the new virus steals part of the cell's outer envelope. This envelope, which acts as a covering, is studded with protein/sugar combinations called HIV glycoproteins. These HIV glycoproteins are necessary for the virus to bind to CD4 and co-receptors. The immature virus breaks free of the infected cell; (7) maturation: The protease enzyme finishes cutting HIV protein chains into individual proteins that combine to make a new working virus. The new copies of HIV can now move on to infect other cells.

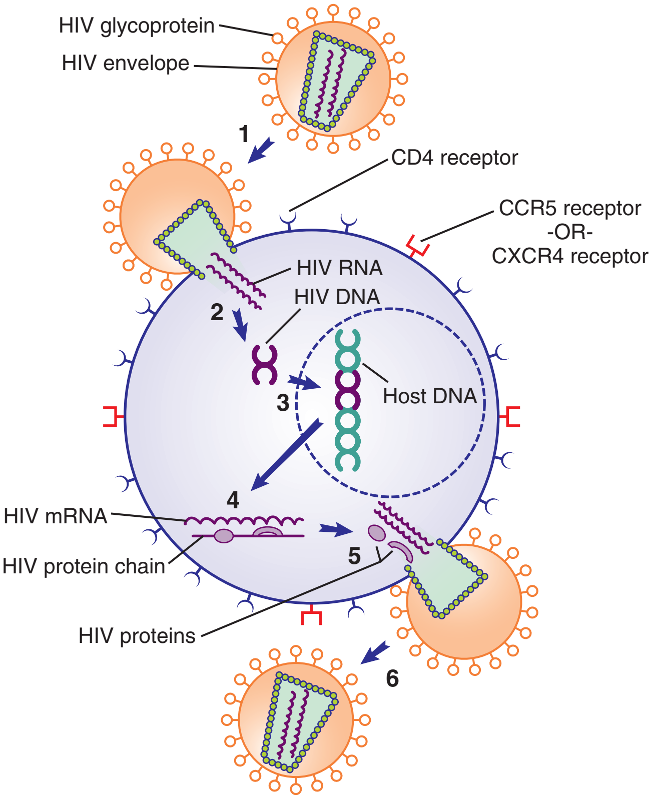

FIGURE 35–1 The life cycle of the human immunodeficiency virus. (Image courtesy of the National Institutes of Health.)

HIV TRANSMISSION

HIV is spread via intimate contact with blood, semen, vaginal fluids, and breast milk. Transmission of the virus occurs primarily by: (1) sexual contact (includes oral, vaginal, and anal sex); (2) direct blood contact (intravenous drug use with shared needles, shared drug works, shared contaminated personal care items such as razors, and blood transfusions [now extremely rare in the United States]); and (3) mother to child (through shared maternal-fetal blood circulation, by direct blood contact during delivery, or in breast milk). Included in these modes are accidental needle injury, artificial insemination with donated semen, and organ transplant. HIV is not spread by casual contact (e.g., hugging), by touching items previously touched by a person infected with the virus, or during participation in sports. Those at highest risk include persons engaging in unprotected sex, those with multiple sexual partners (either the patient themselves or partner[s] of the patient), intravenous drug users who share needles or drug works, and infants born to women with HIV. The risk of mother-to-child transmission (MTCT) is 25% without ART; the risk decreases to 1% to 2% with successful use of ART. Other factors that increase the risk of MTCT are mother with a viral load >1000 copies/mL at delivery, premature rupture of the membranes, hepatitis C virus co-infection, preterm gestation, and vaginal delivery.

LABORATORY TESTING

Several laboratory tests are important for initial patient evaluation upon entry to care, during follow-up evaluation for those not on ART, and before and after initiation or modification of ART to assess for immunologic and virologic efficacy of treatment.

The laboratory tests used to determine when to initiate medication therapy and to monitor efficacy of therapy and indications for changing therapy are **CD4 T-cell** count, plasma HIV RNA quantitative assay (or **viral load** [VL] test), and HIV resistance testing.

The count reflects the number of CD4 cells circulating in the blood. The result is listed as an absolute number and a relative percentage. The absolute count can vary in the same patient depending on laboratory used, time of day laboratory blood work is drawn, or acute illness. The CD4 percentage is a more stable reflection of the **immune system** and is used in conjunction with the absolute count to monitor health status and response to medication therapy. The patient should be encouraged to use the same laboratory at approximately the same time of day to promote consistency of results. The nurse should monitor the laboratory used, because lab value references vary from laboratory to laboratory. The HIV viral load is indicative of the level of virus circulating in the blood and is the best determinant of treatment efficacy. Two FDA-approved commercially available assays commonly used are the quantitative polymerase chain reaction assay and the branched-chain DNA. A key goal of therapy is to achieve and maintain a viral load below the limits of detection (<20 to 40 copies/mL, depending on assay used). This goal should be achieved in 16 to 24 weeks of therapy.

HIV Resistance Testing

Resistance to antiretroviral medications leads to treatment failure and to risk of transmitting drug-resistant virus. Determination of the presence of a drug-resistant strain of HIV is important to prevent ineffective medication treatment. Two types of testing are available: Genotypic resistance testing identifies mutations in the genetic code of HIV associated with drug resistance. Phenotypic testing determines if the patient's HIV is able to replicate in the presence of specific antiretroviral medications. Genotypic resistance testing is recommended upon entry into care, regardless of whether ART will be started immediately.

Additional Laboratory Evaluation

Screening for HLA-B5701 determines if the patient has a mutation associated with a hypersensitivity reaction to abacavir (Ziagen). Those with a positive HLA-B5701 result should not receive abacavir and should have it listed as a drug allergy. This test should be done and results reviewed before abacavir is considered as part of a treatment regimen.

A viral tropism assay should be done before initiation of a CCR5 antagonist medication.

CLASSIFICATION

HIV disease staging and classification systems are important tools for tracking and monitoring the HIV epidemic and providing the clinician and patient with information about HIV disease stage and clinical management.

The two major classification systems are the Centers for Disease Control and Prevention (CDC) staging system (revised in 1993 and 2008) and the World Health Organization (WHO) system (last revised in 2007). In December 2008, CDC published *Revised Surveillance Case Definitions for HIV Infection Among Adults, Adolescents, and Children Aged <18 Months and for HIV Infection and AIDS Among Children Aged 18 Months to <13 Years—United States, 2008* (*www.cdc.gov/mmwr/preview/mmwrhtml/rr5710a1.htm*).

The CDC system assesses the severity of HIV disease by CD4 cell counts and by presence of specific HIV-related conditions; the system is based on the lowest documented CD4 cell count (nadir CD4) and on previously diagnosed HIV-related conditions. The WHO system is useful in resource-constrained settings without access to CD4 cell measurements and classifies HIV disease on the basis of clinical manifestations that clinicians and those with varying levels of HIV expertise and training can recognize in diverse settings.

TREATMENT GOALS

The primary goals for initiating ART are to reduce HIV-associated morbidity and mortality and prolong the duration and quality of life; restore and preserve immunologic function; maximally and durably suppress plasma HIV viral load; and prevent HIV transmission.

INDICATIONS FOR ANTIRETROVIRAL THERAPY

Recommendations for HIV management, including initiation and ongoing treatment with **antiretroviral** medications, change rapidly based on updated clinical data and expert medical opinion. Guidelines for the Use of Antiretroviral Agents in HIV 1 Infected Adults and Adolescents have been developed by the U.S. Department of Health and Human Services (DHHS) Expert Panel on Antiretroviral Guidelines for Adults and Adolescents. This panel recommends ART for all HIV-infected individuals. The strength of this recommendation varies based on pretreatment CD4 cell count; however, regardless of CD4 count, ART is strongly recommended for HIV-infected pregnant patients; for those with a history of an AIDS-defining illness, HIV-associated nephropathy, or HIV and hepatitis B coinfection; and for serodiscordant couples. The panel posts updated information regularly at *http://aidsinfo.nih.gov*.

With increased treatment options and a better understanding of the risks of untreated HIV infection or uncontrolled viremia, there is a shift toward earlier consideration of ART. Suppression of HIV with ART may decrease inflammation and immune activation that is thought to contribute to higher rates of cardiovascular, kidney, and liver disease, neurologic complications, and malignancy in HIV-infected cohorts. If therapy is to be initiated, medications are selected based on results of genotypic resistance testing where applicable; co-morbidities (e.g., liver disease, renal dysfunction, depression); potential drug-drug interactions; pregnancy status; and assessment of patient's willingness and readiness to start therapy. Evaluation of medication readiness should include dosage regimen, pill burden, dosing frequency, food restrictions, side effects, and patient's daily routine. Tools for promoting medication adherence (e.g., alarms, pill planners) and plans for management of potential medication side effects should be reviewed before medication initiation. The patient should be instructed in the need for >95% medication adherence, the potential for development of medication resistance with less than optimal adherence, and clinical implications of resistance.

CLASSES OF ANTIRETROVIRAL MEDICATIONS

Reverse transcriptase inhibitors, protease inhibitors (PIs), **entry (fusion) inhibitors, CCR5 antagonists,** and **integrase inhibitors** make up the classification of drugs known as *antiretroviral therapy.* Reverse transcriptase inhibitors (RT inhibitors) are further divided into **nucleoside/nucleotide** (NRTI) **analogues** and **non-nucleoside** (NNRTI) **analogues.** More than 20 different antiretroviral agents are FDA approved, and various agents are available in fixed-dose combinations that contain two or more HIV medications from one or more drug classes. PIs have changed the prognosis for millions of patients infected with HIV. PIs combined with RT inhibitors can reduce viral plasma levels to undetectable levels, offering significant clinical benefits.

The most recent additions include maraviroc (Selzentry) a CCR5 antagonist; raltegravir (Isentress) and dolutegravir (Tivicay), integrase inhibitors; and etravirine (Intelence) and rilpivirine (Edurant), nucleoside reverse transcriptase inhibitors.

Antiretroviral Agents

Since the 1980s, when zidovudine monotherapy showed survival benefits in advanced HIV patients, much progress has been made. Newer agents have improved adherence (e.g., fewer pills for more convenient dosing, formulation changes that reduce dosing frequency or pill burden, combination dosage forms with two or three drugs in one pill). Other improvements include increased potency, improved side-effect profile (e.g., decreased gastrointestinal effects), and protease-inhibitor boosting with ritonavir.

ART is the standard of care in the treatment of HIV infection. The following combinations are preferred regimens for antiretroviral-naïve patients:

- Efavirenz (NNRTI)/tenofovir (NRTI)/emtricitabine (NRTI)
- Ritonavir-boosted atazanavir (PI) plus tenofovir (NRTI)/emtricitabine (NRTI)
- Ritonavir-boosted darunavir (PI) plus tenofovir (NRTI)/emtricitabine (NRTI)
- Raltegravir (integrase inhibitor) plus tenofovir (NRTI)/emtricitabine (NRTI)

Nucleoside/Nucleotide Reverse Transcriptase Inhibitors

Seven NRTIs are approved for use in the United States: zidovudine (Retrovir), didanosine (Videx), stavudine (Zerit), lamivudine (Epivir), abacavir (Ziagen), tenofovir (Viread), and emtricitabine (Emtriva). Six fixed-dose combination products are also available: Combivir (lamivudine/zidovudine), Trizivir (Abacavir/lamivudine/zidovudine), Epzicom (abacavir/lamivudine), Atripla (efavirenz/emtricitabine/tenofovir), Truvada (emtricitabine/tenofovir), and Complera (rilpivirine/emtricitabine/tenofovir). Tenofovir (Viread) is the only nucleotide analogue.

NRTIs, the foundation of ART, act by interfering with HIV viral RNA-dependent DNA polymerase, resulting in inhibition of viral replication. Two of these agents are typically included in initial ART regimens. The preferred dual NRTI is tenofovir/emtricitabine (or zidovudine/lamivudine in pregnant patients).

All NRTIs except didanosine should be taken with food for optimal tolerability. Didanosine should be taken 60 minutes before meals or 2 hours after meals for optimal absorption. With the exception of abacavir, NRTIs require dosage adjustment in persons with renal insufficiency (creatinine clearance <50 mL/min). Similarly, fixed-dose NRTI combinations should be avoided in patients with renal insufficiency. Gastrointestinal side effects (e.g., nausea, diarrhea, abdominal pain) are transient and improve within the first 2 weeks of therapy.

As a class, NRTIs are associated with changes in the body's metabolism secondary to mitochondrial toxicity. Complications include peripheral neuropathy, myopathy, pancreatitis, and lipoatrophy. Lipoatrophy, or wasting of fat on the extremities, face, and buttocks, is associated with chronic NRTI administration. Rare fatalities have occurred owing to lactic acidosis and hepatic steatosis associated with NRTIs. Drug interactions are uncommon with NRTIs. Gastrointestinal complaints and mitochondrial toxicity are less likely to occur with tenofovir. The most serious side effect with tenofovir is renal toxicity, which occurs rarely.

Adherence with NRTIs can be improved with once-daily dosing (possible with abacavir, didanosine, emtricitabine, lamivudine, and tenofovir) and with fixed-dosage combination products (e.g., Combivir and Truvada).

Prototype Drug Chart 35-1 gives pharmacologic data for zidovudine, and Prototype Drug Chart 35-2 shows the data for tenofovir.

Non-Nucleoside Reverse Transcriptase Inhibitors

Five NNRTIs are used in the United States: efavirenz (Sustiva), delavirdine (Rescriptor), nevirapine (Viramune), rilpivirine (Edurant), and etravirine (Intelence). NNRTIs prevent viral replication by competing with binding of the reverse transcriptase enzyme at the active site. The primary advantage of using NNRTIs is to reserve a protease-inhibitor–based therapy for future use. In general, an NNRTI regimen has a lower pill burden compared with most PI-based regimens. Major disadvantages are the prevalence of NNRTI-resistant viral strains and the low genetic barrier of NNRTIs for development of resistance. (Resistance testing is recommended for treatment-naïve patients before starting therapy.) NNRTIs also have the potential for drug interactions.

Efavirenz is the first-choice drug within the NNRTI class. It should be used with caution in pregnancy because neural tube defects have been reported after early human gestational exposure. Central nervous system (CNS) toxicities, including dizziness, sedation, nightmares, euphoria, or loss of concentration, may occur in up to 50% of patients. Efavirenz should be used cautiously in patients with depression or history of psychiatric or mental illness. Efavirenz is optimally administered as a component of Atripla, given once daily at bedtime on an empty stomach or with a low-fat meal to prevent excessive drug absorption.

Nevirapine may be used as an alternative in adult patients during pregnancy (especially during the first trimester) or in patients who are planning to conceive or are not using effective and consistent contraception. Nevirapine has a greater risk of severe rash and hepatotoxicity. Delavirdine appears to

PROTOTYPE DRUG CHART 35-1

Zidovudine

Drug Class

Nucleoside reverse transcriptase inhibitor
Trade names: ZDV, AZT, Retrovir
Pregnancy category: C
FDA approved: 1987
Estimated annual cost: $6700 (brand), $4350 (generic)

Dosage

Prevention of maternal-fetal HIV transmission
Maternal therapy: PO: 100 mg 5 times/d until the start of labor
Intrapartum: IV: 2 mg/kg loading dose over 30-60 min followed by continuous infusion of 1 mg/kg/h until cord is clamped. For scheduled cesarean delivery, begin IV 3 h before surgery
Newborn (syrup): PO: Continue dose through 6 wk of age
Infant (full-term): PO: 4 mg/kg/dose b.i.d. (IV: 1.5 mg/kg/dose q6h).
Infant (30-36 wk gestation at birth): PO: 2 mg/kg/dose q12h; at 2 wk of age, 3 mg/kg/dose q12h (IV: 1.5 mg/kg/dose q12h; at 2 wk of age, advance to 2.3 mg/kg/dose q12h)
Infant (<30 weeks gestation at birth): PO: 2 mg/kg/dose q12h; at 4 wk of age, 3 mg/kg/dose q12h (IV: 1.5 mg/kg/dose q12h; at 4 wk of age, 2.3 mg/kg/dose q12h)
Treatment:
A: PO: 200 mg q8h or 300 mg q12h; IV: 1 mg/kg q4h (ATC: 5-6 doses/d)
C: 4 wk to <18 y: PO: ≥30 kg: 300 mg b.i.d.; 9-29 kg: 9 mg/kg/dose b.i.d.; 4-8 kg: 12 mg/kg/dose b.i.d.
C: 6 wk-11 y: IV: 120 mg/m^2/dose q6h or 20 mg/m^2/h; ≥12 y: 1 mg/kg/dose q4h ATC (5-6 doses/d)

Contraindications

Life-threatening allergies to zidovudine or components of preparation
Caution: Bone marrow compromise, renal and hepatic dysfunction, decreased hepatic blood flow

Drug-Lab-Food Interactions

Drug: Ganciclovir, probenecid, valproic acid may increase concentration/adverse effects. Rifampin may decrease concentration/effects.
Lab: May increase ALT, AST

Pharmacokinetics

Absorption: PO: 66%-70%
Distribution: PB: 25%-38%, crosses blood-brain barrier, crosses placenta, peak serum levels: 30-90 min
Metabolism: t½: 0.5-3 h; extensive first-pass effect in liver
Excretion: 63%-95% in urine

Pharmacodynamics

Not applicable

Therapeutic Effects/Uses

Management of patients with HIV infection; prevention of maternal-fetal HIV transmission
Mode of Action: Inhibits viral enzyme reverse transcriptase, an enzyme necessary for viral HIV replication

Side Effects

Numbness, tingling, burning and pain in lower extremities, abdominal pain, rash, GI intolerance, fever, sore throat, headache, pruritus, muscle pain, difficulty swallowing, arthralgia, insomnia, confusion, mental changes, bluish-brown bands on fingernails

Adverse Reactions

Nausea, vomiting, anemia (pale skin, unusual fatigue or weakness), neutropenia (fever, chills, sore throat), seizures

A, Adult; *b.i.d.,* twice a day; *C,* child; *d,* day; *FDA,* Food and Drug Administration; *GI,* gastrointestinal; *h,* hour; *HIV,* human immunodeficiency virus; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; *t½,* half-life; *wk,* week; *y,* year; >, greater than; ≥, greater than or equal to; <, less than.

have the least potent antiviral activity and is not recommended as part of an initial regimen.

Etravirine is the first agent in this group to show antiviral activity in treatment-experienced patients with HIV that was resistant to an NNRTI and other antiretroviral agents. Etravirine also has many drug interactions, including combinations with fosamprenavir/ritonavir, atazanavir/ritonavir, other NNRTIs, carbamazepine, phenobarbital, and rifampin. Common side effects include rash (during the first 6 weeks of therapy), diarrhea, nausea, fatigue, abdominal pain, peripheral neuropathy, headache, and hypertension. Etravirine has been associated with potentially life-threatening and fatal skin reactions (e.g., Stevens-Johnson syndrome).

Prototype Drug Chart 35-3 presents the pharmacologic data for efavirenz.

PROTOTYPE DRUG CHART 35-2

Tenofovir

Drug Class

Nucleotide reverse transcriptase inhibitor (NtRTI)
Trade name: Viread
Pregnancy category: B
FDA approved: 2001
Estimated annual cost: $10,480

Dosage

A/C ≥12 y: PO: 300 mg once daily with or without food (high-fat meals may increase bioavailability)

Contraindications

None listed in FDA-approved labeling
Caution: Renal and hepatic dysfunction

Drug-Lab-Food Interactions

Drug: acyclovir, ganciclovir, valganciclovir may increase levels/adverse effects of tenofovir
Lab: may increase triglycerides, AST, ALT, alkaline phosphatase

Pharmacokinetics

Absorption: PO: 25%-40%
Distribution: PB: <7% to proteins, peak serum levels: 36-84 min fasting; 96-144 min with food
Metabolism: $t_{1/2}$: converted intracellularly by hydrolysis to tenofovir, then phosphorylated to active tenofovir diphosphate
Excretion: 70%-80% primarily in urine as unchanged drug

Pharmacodynamics

Not applicable

Therapeutic Effects/Uses

Management of patients with HIV infection; treatment of chronic hepatitis B
Mode of Action: Inhibits viral enzyme reverse transcriptase, an enzyme necessary for viral HIV replication

Side Effects

Diarrhea, nausea, vomiting, flatulence, insomnia, dizziness, depression, fever

Adverse Reactions

Lactic acidosis, hepatomegaly with steatosis

A, Adult; *C,* child; *d,* day; *FDA,* Food and Drug Administration; *GI,* gastrointestinal; *h,* hour; *HIV,* human immunodeficiency virus; *IV,* intravenous; *max,* maximum; *min,* minute; *PB,* protein-binding; *PO,* by mouth; $t_{1/2}$, half-life; *wk,* week; *y,* year; >, greater than; ≥, greater than or equal to; <, less than.

Protease Inhibitors

PI-based regimens (one or two PIs plus two NRTIs) have revolutionized the treatment of HIV infection, leading to sustained viral suppression, improved immunologic function, and prolonged patient survival. Nine PIs are approved by the FDA: lopinavir/ritonavir (Kaletra), atazanavir (Reyataz), fosamprenavir (Lexiva), tipranavir (Aptivus), darunavir (Prezista), saquinavir (Invirase), indivavir (Crixivan), ritonavir (Norvir), and nelfinavir (Viracept). Unlike NRTIs and NNRTIs, PIs act at the end of the HIV life cycle to target viral assembly by inhibiting the activity of protease, an enzyme used to cleave nascent proteins for final assembly of new virons, resulting in formation and release of immature, defective and noninfectious virus particles. Each PI has unique characteristics based on clinical efficacy, side-effect profile, and pharmacokinetic properties. Darunavir or atazanavir (both "boosted" with ritonavir) are first-line choices of PIs in ART.

Selection of a PI-based regimen should consider dosing frequency, food and fluid requirements, pill burden, drug interaction potential, and side-effect profile. When initiating therapy with PIs, gastrointestinal side effects (nausea, vomiting, and diarrhea) can be bothersome and may negatively affect adherence. Metabolic abnormalities, including significant elevation of cholesterol and triglycerides, fat maldistribution, and insulin resistance/diabetes are associated with PI use, with each PI differing in its propensity to cause these metabolic complications. Atazanivir, a preferred PI for initial ART, has not reported insulin resistance and is less likely to elevate cholesterol and triglycerides. Metabolic abnormalities are established risk factors for cardiovascular disease, including myocardial infarction and hypertension, so lifestyle modifications, smoking cessation, exercise, and cardiac risk management are advised for those receiving chronic PI-based therapies.

Ritonavir boosting is a relatively new concept and one of the mainstays of PI therapy. The potent inhibitory effect of ritonavir on the cytochrome P450 3A4 isoenzyme allows the addition of 100 to 200 mg of ritonavir to other PIs as a pharmacokinetic booster. This helps to reduce dietary restrictions, increase drug exposure, inhibit metabolism, and maximize blood levels of the co-administered PI, thus reducing dosing frequency and pill burden and overcoming viral resistance. Because "boosted" regimens may be less complex, patients may be able to follow and tolerate them better.

Prototype Drug Chart 35-4 presents the pharmacologic data for atazanavir.

Entry Inhibitors

Enfuvirtide (Fuzeon) is the only agent approved in this class. Enfuvirtide acts by a mechanism that inhibits gp41 fusion to

PROTOTYPE DRUG CHART 35-3

Efavirenz

Drug Class

Nonnucleoside reverse transcriptase inhibitor (NNRTI)
Trade name: Sustiva
Pregnancy category: D
FDA approved: 1998
Estimated annual cost: $8275

Dosage

Note: Dose given at bedtime to minimize CNS adverse effects
A: PO: 600 mg once daily
C: PO: 10-<15 kg: 200 mg daily; 15-<20 kg: 250 mg daily; 20-<25 kg: 300 mg daily; 25-<32.5 kg: 350 mg daily; 32.5-<40 kg: 400 mg daily; ≥40 kg: 600 mg daily

Contraindications

Life-threatening allergies to efavirenz or components of preparation; concurrent use of midazolam, triazolam, ergot alkaloids
Caution: Patients with history of mental illness or drug abuse; liver impairment; seizure disorder

Drug-Lab-Food Interactions

Drug: carbamazepine, nevirapine, phenobarbital, phenytoin, rifampin; St. John's wort may decrease effect of atorvastatin, bupropion, clarithromycin, clopidrogel, methadone, and sertraline. See Contraindications.
Food: Avoid alcohol because of liver/CNS adverse effects; high-fat meals increase absorption

Pharmacokinetics

Absorption: PO: Increased following high-fat meal
Distribution: PB: >99%, widely distributed (found in CSF)
Metabolism: $t\frac{1}{2}$: 40-55 h; metabolized in liver Time to peak levels: 3-5 h
Excretion: 16%-41% in feces, primarily as unchanged drug; 14%-34% in urine, primarily as metabolite

Pharmacodynamics

Not applicable

Therapeutic Effects/Uses

Treatment of HIV-1 infections in combination with at least two other antiretroviral agents.
Mode of Action: Binds to reverse transcriptase, blocking RNA-dependent and DNA-dependent DNA polymerase activity including HIV-1 replication.

Side Effects

Rash; CNS effects (dizziness, insomnia, abnormal dreams/thinking, impaired concentration, amnesia, agitation, hallucinations, euphoria, anxiety); nausea, diarrhea

Adverse Reactions

Aggressive reaction, allergic reaction, convulsion, liver failure, neuropathy, suicide, abnormal vision

A, Adult; *C,* child; *CNS,* central nervous system; *CSF,* cerebrospinal fluid; *DNA,* deoxyribonucleic acid; *FDA,* U.S. Food and Drug Administration; *h,* hour; *HDL,* high-density lipoprotein; *HIV-1,* human immunodeficiency virus-1; *PB,* protein-binding; *PO,* by mouth; *RNA,* ribonucleic acid; $t\frac{1}{2}$, half-life; >, greater than; ≥, greater than or equal to; <, less than.

prevent HIV cell entry. This class of agents targets prevention of the fusion of the HIV and CD4 cell and prevents passing the viral genome to the CD4 cell. Enfuvirtide is indicated only in combination with three to five other antiretroviral agents for patients with limited treatment options requiring salvage therapy. It is expensive, and the medication must be taken by subcutaneous injection in a dose of 90 mg twice daily.

Enfuvirtide does not require dosage adjustment in patients with renal failure or hepatic impairment. It is not metabolized by CYP enzymes and is not associated with any CYP-mediated drug-drug interactions. Injection-site reactions (e.g., subcutaneous nodules, redness) occur in up to 98% of patients. Other side effects reported include rash and diarrhea. Serious allergic reactions, including anaphylaxis, fever, and hypotension, have occurred in less than 1% of patients.

CCR5 Co-Receptor Antagonists

Maraviroc, the only agent in this class, blocks the CCR5 co-receptor needed for CCR5-tropic HIV entry into immune cells, preventing viral replication. When combined with at least two other antiretroviral agents, it is effective in about 50% of patients having resistance to most classes of antiretroviral agents. For maraviroc to be effective, it is important to ensure that the HIV uses the CCR5 co-receptor rather than the CXCR4 co-receptor or a mix of both receptors for viral entry. A blood test documenting the presence of the CCR5 receptor (tropism test) must be obtained before starting the medication.

Maraviroc is indicated in combination with other antiretroviral agents for treatment-experienced adult patients with evidence of viral replication and HIV-1 strains resistant to multiple antiretroviral therapy. The most common side effects are cough, pyrexia, upper respiratory tract infection, rash, abdominal pain, and dizziness. Possible drug-induced hepatotoxicity with allergy-type features has been reported. Use caution in patients with liver or heart disease or a history of orthostatic hypotension and in those on medication that lowers blood pressure.

PROTOTYPE DRUG CHART 35-4

Atazanavir

Drug Class

Protease inhibitor
Trade name: Reyataz
Pregnancy category: B
FDA approved: 2003
Estimated annual cost: $14,115

Dosage

Treatment Naïve

A: PO: 300 mg plus ritonavir 100 mg once daily or 400 mg once daily if unable to tolerate ritonavir
C: PO: 6-17 y, ≥39 kg: same as adult; 32-38 kg: 250 mg with ritonavir 100 mg once daily; 25-31 kg: 200 mg with ritonavir 100 mg once daily; 15-24 kg: 150 mg with ritonavir 80 mg once daily

Treatment Experienced

A: PO: 300 mg plus ritonavir 100 mg once daily
C: PO: 6-17 y, 39 kg or greater: same as adult; 32-38 kg: 250 mg with ritonavir 100 mg once daily; 25-31 kg: 200 mg with ritonavir 100 mg once daily

Contraindications

Hypersensitivity to atazanavir or any component, concurrent use with alfuzosin, ergot derivatives, lovastatin, midazolam (oral), rifampin, simvastatin, St. John's wort
Caution: Patients with pre-existing conduction abnormalities (may prolong PR interval), hepatitis B or C, hepatic impairment, hemophilia A or B

Drug-Lab-Food Interactions

Drug: azole antifungals, clarithromycin may increase levels/adverse effects; antacids, carbamazepine, H_2 antagonists, proton pump inhibitors, rifampin may decrease levels/effects. See Contraindications.
Lab: May increase liver function tests, cholesterol, triglycerides, glucose
Food: Bioavailability increased when taken with food

Pharmacokinetics

Absorption: PO: Rapidly, increased with food
Distribution: PB: 98%, peak levels attained in 2-3 h
Metabolism: $t\frac{1}{2}$: 7-8 h (9-18 h when boosted with ritonavir). Metabolized in liver
Excretion: Primarily fecal elimination (70%); urine (13%)

Pharmacodynamics

Not applicable

Therapeutic Effects/Uses

Treatment of HIV-1 infection in combination with other antiretroviral agents.
Mode of Action: Inhibits HIV protease, rendering enzyme incapable of processing polyprotease precursors; production of noninfectious immature HIV particles results

Side Effects

Rash, nausea, cough

Adverse Reactions

Hyperglycemia, diabetes mellitus, jaundice

A, Adult; *b.i.d.,* twice a day; *C,* child; *FDA,* U.S. Food and Drug Administration; *h,* hour; *HIV,* human immunodeficiency virus; *mo,* month; *PB,* protein-binding; *PO,* by mouth; $t\frac{1}{2}$, half-life; *y,* year; >, greater than; ≥, greater than or equal to; <, less than.

Integrase Inhibitors

Raltegravir and dolutegravir exert their action by interfering with integrase, the enzyme that HIV needs to multiply, thus limiting the ability of the virus to replicate and infect new cells. They are used for the treatment of HIV-1 infections with at least two or three other antiretroviral agents in both treatment-naïve (recommended initial agent) and treatment-experienced patients. Common side effects of raltegravir include nausea, headache, diarrhea, and pyrexia. Caution is advised in patients who are at increased risk for certain types of muscle problems (e.g., myopathy and rhabdomyolysis), including patients who take medications that can increase risk, such as statins. Raltegravir is administered twice daily. Common side effects of dolutegravir include insomnia and headache. Dolutegravir is administered once daily (twice daily when given with efavirenz, fosamprenavir/ritonavir, tipranavir/ritonavir, or rifampin).

Table 35-2 shows the respective routes, dosages, and considerations of antiretroviral agents. Information on drug interactions is shown in Table 35-3.

IMMUNE RECONSTITUTION INFLAMMATORY SYNDROME

Immune reconstitution inflammatory syndrome (IRIS) is related to specific opportunistic pathogens and is experienced

TABLE 35-2 ANTIRETROVIRAL AGENTS

NAME	AVAILABILITY	DOSAGE	COMMENTS
Nucleoside Reverse Transcriptase Inhibitors (NRTIs)			
abacavir (ABC) (Ziagen) Trizivir (with ZDV + 3TC) Epzicom (with 3TC)	Ziagen: 300-mg tabs 20-mg/mL oral solution Trizivir: ABC 300 mg, ZDV 300 mg, 3TC 150 mg Epzicom: ABC 600 mg, 3TC 300 mg	Ziagen: 300 mg b.i.d. or 600 mg once daily Trizivir: 1 tab b.i.d. Epzicom: 1 tab once daily	Take without regard to meals Metabolized by alcohol dehydrogenase Excreted renally Do not use Trizivir and Epzicom for patients with CLcr <50 mL/min t½: 1.5 h Side effects: hypersensitivity reaction (avoid if HLA-B*5701 is positive due to increased risk of hypersensitivity reaction); symptoms include fever, rash, nausea, vomiting, malaise, fatigue, loss of appetite; respiratory symptoms include sore throat, cough, shortness of breath, lactic acidosis with hepatic steatosis
didanosine (DDL) (Videx EC)	Videx EC: 125 mg, 200 mg, 250 mg, 400 mg Videx 10 mg/mL powder for oral solution	Body wt >60 kg: 400 mg once daily or 200 mg b.i.d. With TDF: 250 mg/d Body wt <60 kg: 250 mg/d With TDF: 200 mg/d	Take ½ h before or 2 h after meal Excreted renally; adjust dosage in patients with renal insufficiency t½: 1.5 h Side effects: pancreatitis, peripheral neuropathy, nausea, lactic acidosis with hepatic steatosis (rare), risk of myocardial infarction, retinal changes, optic neuritis, insulin resistance, diabetes
emtricitabine (FTC) (Emtriva) Atripla (with EFV + TDF) Truvada (with TDF) Complera (with TDF and RPL)	Emtriva: 200 mg caps 10 mg/mL oral solution Atripla: EFV 600, FTC 200 mg, TDF 300 mg Truvada: FTC 200 mg, TDF 300 mg Complera: FTC 200 mg, RPL 25 mg, TDF 300 mg	Emtriva: 200-mg cap once daily or 240 mg oral solution once daily Atripla: 1 tab once daily Truvada: 1 tab once daily Complera: 1 tab once daily	Take without regard to meals Excreted renally; adjust dosage in patients with renal insufficiency Do not use Atripla/Complera for patients with CLcr <50 mL/min; Do not use Truvada for patients with CLcr <30 mL/min t½: 10 h Side effects: lactic acidosis with hepatic steatosis (rare), hyperpigmentation, skin discoloration
lamivudine (3TC) (Epivir) Combivir (with ZDV) Epizicom (with ABC) Trizivir (with ZDV + ABC)	Epivir: 150-mg, 300-mg tabs 10-mg/mL oral solution Combivir: 3TC 150 mg, ZDV 300 mg Epzicom: ABC 600 mg, 3TC 300 mg Trizivir: ABC 300 mg, ZDV 300 mg, 3TC 150 mg	Epivir: 150 mg b.i.d. or 300 mg once daily Combivir: 1 tab b.i.d. Epizicom: 1 tab once daily Trizivir: 1 tab b.i.d.	Take without regard to meals Excreted renally; adjust dosage in patients with renal insufficiency Do not use Combivir, Trizivir, Epizicom for patients with CLcr <50 mL/min t½: 5-7 h Side effects: minimal toxicity, lactic acidosis with hepatic steatosis (rare)
stavudine (d4T) (Zerit)	Zerit: 15-mg, 20-mg, 30-mg, 40-mg caps 1 mg/mL powder for oral solution	Body wt ≥60 kg: 40 mg b.i.d. Body wt <60 kg: 30 mg b.i.d.	Take without regard to meals Excreted renally; adjust dosage in patients with renal insufficiency t½: 1 h Side effects: peripheral neuropathy, lipodystrophy, pancreatitis, hyperlipidemia, rapidly progressive ascending neuromuscular weakness (rare), lactic acidosis with hepatic steatosis (rare)
tenofovir (TDF) (Viread) Atripla (with EFV+FTC) Truvada (with FTC) Complera (with FTC and RPL)	Viread: 150-mg, 200-mg, 250-mg, 300-mg tabs Atripla: EFV 600, FTC 200 mg, TDF 300 mg Truvada: FTC 200 mg, TDF 300 mg Complera: FTC 200 mg, RPL 25 mg, TDF 300 mg	Viread: 1 300-mg tab/d without regard to meals Atripla: 1 tab h.s. on empty stomach Truvada: 1 tab/d without regard to meals Complera: 1 tab/d with food	Excreted renally; adjust dosage in patients with renal insufficiency Do not use Atripla/Complera for patients with CLcr <50 mL/min; do not use Truvada for patients with CLcr <30 mL/min t½: 17 h Side effects: asthenia, headache, diarrhea, nausea, vomiting, flatulence, renal insufficiency, osteomalacia, lactic acidosis with hepatic steatosis (rare)

TABLE 35-2 ANTIRETROVIRAL AGENTS—cont'd

NAME	AVAILABILITY	DOSAGE	COMMENTS
zidovudine (AZT, ZDV) (Retrovir) Combivir (with 3TC) Trizivir (with 3TC + ABC)	Retrovir: 100-mg caps 300-mg tabs 10-mg/mL IV solution 10-mg/mL oral solution Combivir: 3TC 150 mg, ZDV 300 mg Trizivir: ABC 300 mg, ZDV 300 mg, 3TC 150 mg	Retrovir: 300 mg b.i.d. or 200 mg t.i.d. Combivir: 1 tab b.i.d. Trizivir: 1 tab b.i.d.	Take without regard to meals Excreted renally; adjust dosage in patients with renal insufficiency Do not use Combivir, Trizivir for patients with CLcr <50 mL/min t½: 1.1 h Side effects: bone marrow suppression, macrocytic anemia, neutropenia, GI intolerance, headache, insomnia, asthenia, lactic acidosis with hepatic steatosis (rare)
Non-Nucleoside Reverse Transcriptase Inhibitors (NNRTIs)			
delavirdine (DLV) (Rescriptor)	Rescriptor: 100-mg, 200-mg tabs	400 mg t.i.d. (100 mg may be mixed with 3 oz water; 200-mg tabs taken as intact tablets)	Take without regard to meals Metabolized by cytochrome P450, excreted in urine/feces t½: 5.8 h Side effects: rash, increased transaminase levels, headaches
efavirenz (EFV) (Sustiva) Atripla (with TDF + FTC)	Sustiva: 50-mg, 200-mg caps 600-mg tabs Atripla: EFV 600, FTC 200 mg, TDF 300 mg	Sustiva: 600 mg h.s. or before on empty stomach Atripla: 1 tab/d h.s. or before	Take on empty stomach, high-fat/high-caloric meals increase concentration. Metabolized by cytochrome P450 Sustiva: no dosage adjustment in renal insufficiency Do not use Atripla for patients with CLcr <50 mL/min t½: 40-55 h Side effects: rash, increased transaminase levels, CNS symptoms including dizziness, confusion, agitation, hallucinations, euphoria
etravirine (ETR) (Intelence)	25-mg, 100-mg, 200-mg tabs	200 mg b.i.d. after a meal	Caloric meals increase concentration Metabolized by cytochrome P450 No dosage adjustment in patients with renal insufficiency t½: 41 +/– 20 h Side effects: rash including Stevens-Johnson syndrome, nausea
rilpivirine (RPL) (Edurant) Complera (with FTC and TDF)	Edurant: 25-mg tab Complera: FTC 200 mg, RPL 25 mg, TDF 300 mg	Edurant: 25 mg/d Complera: 1 tab once daily with food	Take with a meal t½: 50 h Side effects: rash depression, headache, insomnia
nevirapine (NVP) (Viramune, Viramune XR)	Viramune: 200-mg tabs 50-mg/5-mL oral suspension Viramune ER: 100-mg, 400-mg tabs	Viramune: 200 mg/d for 14 d, then 200 mg b.i.d. Viramune ER: 400 mg once daily	Take without regard to meals Metabolized by cytochrome P450 t½: 25-30 h Side effects: rash, including Stevens-Johnson syndrome, symptomatic hepatitis
Protease Inhibitors (PIs)			
atazanavir (ATV) (Reyataz)	Reyataz: 150-mg, 200-mg, 300-mg caps	Reyataz: 400 mg once daily or RTV 100 mg + ATV 300 mg once daily	Take with food; avoid taking with antacids Cytochrome P450 3A4 inhibitor and substrate Adjust dosage in patients with hepatic insufficiency t½: 7 h Side effects: hyperbilirubinemia, prolonged P-R interval (use with caution in patients with underlying conduction defects or concomitant medications that prolong P-R interval), hyperglycemia, fat maldistribution, possible increased bleeding in patients with hemophilia
darunavir (DRV) (Prezista)	Prezista: 75-mg, 150-mg, 600-mg, 800-mg tabs	Prezista: (DRV 600 mg + RTV 100 mg) b.i.d.	Administer with food (increases concentration) Cytochrome P450 3A4 inhibitor and substrate Adjust dosage in patients with hepatic insufficiency t½: 15 h Side effects: rash, diarrhea, nausea, headache, elevated transaminase levels, hyperglycemia, fat maldistribution, possible increased bleeding in hemophiliacs, hyperlipidemia

TABLE 35-2 ANTIRETROVIRAL AGENTS—cont'd

NAME	AVAILABILITY	DOSAGE	COMMENTS
fosamprenavir (fAPV) (Lexiva)	Lexiva: 700-mg tab 50-mg/mL oral suspension	Lexiva: 1400 mg b.i.d. or fAPV 1400 mg + RTV 200 mg/d or fAPV 700 mg + RTV 100 mg b.i.d.	Tablet: Take with or without food Oral suspension: Take with food Cytochrome P450 3A4 inhibitor, inducer, and substrate Adjust dosage in patients with hepatic insufficiency t½: 7.7 h Side effects: rash, diarrhea, nausea, vomiting, headache, hyperlipidemia, elevated transaminase levels, hyperglycemia, fat maldistribution, possible increased bleeding in hemophiliacs
indinavir (IDV) (Crixivan)	Crixivan: 200-mg, 400-mg caps	Crixivan: 800 mg every 8 h With RTV: IDV 800 mg + RTV 100 mg or 200 mg q12h	Unboosted: take 1 h before or 2 h after meals; with RTV: may take with or without meals Cytochrome P450 3A4 inhibitor and substrate Adjust dosage in patients with hepatic insufficiency t½: 1.5-2 h Side effects: nephrolithiasis, GI intolerance, nausea, indirect hyperbilirubinemia, headache, asthenia, blurred vision, dizziness, rash, metallic taste, thrombocytopenia, alopecia, hemolytic anemia, hyperlipidemia, elevated transaminase levels, hyperglycemia, fat maldistribution, possible increased bleeding in patients with hemophilia
lopinavir/ritonavir (LPV/r) (Kaletra)	Kaletra: Tab: LPV 200 mg and RTV 50 mg; LPV 100 mg and RTV 25 mg Oral solution: LPV 400 mg and RTV 100 mg/5 mL	Kaletra: LPV 400 mg + RTV 100 mg b.i.d. or LPV 800 mg + RTV 200 mg once daily	May take tablet with or without food; take oral solution with food Cytochrome P450 3A4 inhibitor and substrate t½: 5-6 h Side effects: GI intolerance, nausea, vomiting, diarrhea, asthenia, PR interval prolongation, pancreatitis, hyperlipidemia, elevated transaminase levels, hyperglycemia, fat maldistribution, possible increased bleeding in patients with hemophilia
nelfinavir (NFV) (Viracept)	Viracept: 250-mg, 625-mg tabs	Viracept: 1250 mg b.i.d. or 750 mg t.i.d.	Take with meal or snack Cytochrome P450 3A4 inhibitor and substrate t½: 3.5-5 h Side effects: diarrhea, hyperlipidemia, elevated transaminase levels, hyperglycemia, fat maldistribution, possible increased bleeding in hemophiliacs
ritonavir (RTV) (Norvir)	Norvir: 100-mg tabs 100-mg caps 600 mg/7.5 mL solution	Norvir: Booster: 100-400 mg in 1-2 divided doses	Take with food Cytochrome P450 3A4 potent inhibitor t½: 3-5 h Side effects: GI intolerance, nausea, vomiting, diarrhea, paresthesias, hepatitis, asthenia, taste perversion, hyperlipidemia, hyperglycemia, fat maldistribution, possible increased bleeding in patients with hemophilia
saquinavir (SQV) (Invirase)	Invirase: 200-mg caps 500-mg tabs	Invirase: SQV 1000 mg + RTV 100 mg b.i.d.	Take within 2 h of a meal Cytochrome P450 3A4 inhibitor and substrate t½: 12 h Side effects: GI intolerance, nausea, diarrhea, headache, hyperlipidemia, elevated transaminase levels, hyperglycemia, PR interval prolongation, fat maldistribution, possible increased bleeding in hemophiliacs

Continued

TABLE 35-2 **ANTIRETROVIRAL AGENTS—cont'd**

NAME	AVAILABILITY	DOSAGE	COMMENTS
tipranavir (TPV) (Aptivus)	Aptivus: 250-mg caps 100 mg/mL oral solution	Aptivus: TPV 500 mg + RTV 200 mg b.i.d.	Take with food Cytochrome P450 3A4 inducer and substrate $t_{1/2}$: 6 h Side effects: hepatotoxicity, rash (has sulfonamide moiety), hyperlipidemia, hyperglycemia, fat maldistribution, possible increased bleeding in patients with hemophilia
Entry Inhibitor			
enfuvirtide (T20) (Fuzeon)	Fuzeon: Injection powder 90 mg/mL after reconstitution	Fuzeon: 90 mg subQ b.i.d.	Store vial at room temperature; following reconstitution, refrigerate and use within 24 h $t_{1/2}$: 3.8 h Side effects: local injection site reaction (pain, erythema, induration, nodules, cysts, pruritus, ecchymosis), increased rate of bacterial pneumonia, hypersensitivity reaction (rash, fever, nausea, vomiting, chills, rigors, hypotension, elevated transaminases)
CCR5 Antagonists			
maraviroc (MRV) (Selzentry)	Selzentry: 150-mg, 300-mg tabs	300 mg b.i.d. 150 mg b.i.d. when given with strong CYP3A inhibitors (e.g., itraconazole, clarithromycin) 600 mg b.i.d. when given with strong CYP3A inducers (e.g., rifampin, carbamazepine, phenytoin)	Concentration may increase in renal dysfunction (CrCL <50); use not recommended May need to adjust dose with concomitant medications (interactions) May take without regard to food $t_{1/2}$: 14-18 h Side effects: Fever, upper respiratory tract infection, orthostatic hypotension, hepatotoxicity, rash, cough, abdominal pain, dizziness
Integrase Inhibitors			
raltegravir (RAV) (Isentress)	Isentress: 400-mg tabs	400 mg b.i.d.	Take without regard to food No adjustment needed with renal or hepatic dysfunction Absorption increased with high-fat meal $t_{1/2}$: 8 h Side effects: nausea, headache, diarrhea, pyrexia, increased total cholesterol, fatigue, rash including Stevens-Johnson syndrome and epidermal necrolysis
dolutagravir (Tivicay)	Tivicay: 50-mg tabs	50 mg once/d	Take without regard to meals No adjustment needed with renal or hepatic dysfunction Absorption increased with high-fat meal $t_{1/2}$: 14 h Side effects: headache, insomnia, rash

by a low percentage of patients early in ART. IRIS has two distinct entities: (1) paradoxical IRIS, which is an exacerbation of treated (successful or partial) opportunistic infection (OI); and (2) unmasking IRIS, a response to undiagnosed or subclinical OI. IRIS may occur in response to many pathogens. Diagnosis is a challenge because there are no laboratory markers; it is a condition of exclusion. For example, new OI or concurrent illness must be excluded before IRIS can be diagnosed.

Risk factors for developing IRIS include a low CD4 cell count (particularly <50 cells/mcL) at time of ART initiation and a high baseline HIV RNA. Starting ART soon after

TABLE 35-3 DRUG INTERACTIONS

Drug interaction associated with HAART is a challenging issue facing providers who treat patients with HIV. Medications used as initial treatment are associated with significant drug interactions. Concurrent treatment of comorbid disease states and therapies for preventing and/or treating opportunistic infections further increase the risk of drug interactions.

Nucleoside Reverse Transcriptase Inhibitors (NRTIs)

Drug interactions associated with NRTIs are minimal because these medications are not metabolized by the CYP450 system. Nevertheless, drug interactions may still occur within the class.

Non-Nucleoside Reverse Transcriptase Inhibitors (NNRTIs)

Drugs in this class are prone to interactions because they are extensively metabolized via CYP3A4 and can act as either inducers or inhibitors of CYP3A4. Efavirenz and nevirapine are inducers of CYP3A4, and delavirdine is an inhibitor.

Protease Inhibitors (PIs)

All PIs are potent inhibitors of CYP3A4 and result in drug interactions. Levels of medications also metabolized by the same system have the potential to be markedly increased, leading to an increased incidence of adverse effects. The protease inhibitor ritonavir is the most potent inhibitor of CYP3A4 in this class.

CCR5 Antagonists

CCR5 antagonists are a substrate of CYP3A. Concentrations are significantly increased in the presence of strong CYP3A inhibitors and reduced with CYP3A inducers. Dosage adjustments are necessary when used with these agents.

Integrase Inhibitors

Integrase inhibitor raltegravir is primarily eliminated by glucouronidation mediated by UDP-glucuronosyltransferase enzymes (UGTIA1). Strong inducers of UGTIA1 enzymes can significantly decrease the concentration of raltegravir.

b.i.d., Twice a day; *d,* day; *h,* hour; *t.i.d.,* three times a day; *wk,* week.

initiation of treatment for recognized OI also increases risk for IRIS. Severity of IRIS ranges from mild to life-threatening. Treatment varies according to specific pathogen and clinical situation but typically includes continuing ART if possible, treating the OI as indicated, and adding antiinflammatory therapy (including corticosteroids) as needed.

NURSE'S ROLE IN ANTIRETROVIRAL THERAPY

Thorough assessment of the patient's physiologic and psychosocial health needs and literacy levels is required initially and for the duration of care. Follow-up assessment after ART begins should include medication side effects, adherence to regimen, and issues affecting medication adherence. Patients may confuse medication side effects with new onset of symptoms. Careful follow-up assessment can detect the need for additional medical care or medication management.

Adherence challenges are common with any medication therapy, but ART presents a greater challenge as patients are asked to achieve adherence of 95% or greater. Nonadherence can result in HIV viral replication and potential for drug resistance. Multiple strategies for adherence are available and should be discussed with patients. Medication organizers, alarms on cell phones or mobile devices, medication "maps" with pictures, and medication diaries are available tools. Friends, family members, and personal support systems can assist patients with adherence. Nurses can facilitate adherence by allowing sufficient time to educate patients about medications, developing a trusting relationship, and building a partnership with the patient.

Nursing assessment should include asking the reasons for missing medications. These commonly include stigma, forgetting, feeling ill, side effects, not having the medicine when doses are due, pill fatigue, medication costs, loss of health insurance, and lack of transportation to the pharmacy. If barriers to adherence are identified, individualized plans should be addressed with the patient and the HIV care provider.

Patient education should include purpose of each medication, dosage schedule, food and fluid restrictions, recommended food choices, and storage of medications. Additional suggestions include taking medication during a daily routine, such as brushing teeth, or using a medication calendar to track medications taken. The nurse should assess whether scheduled appointments to assist the patient with filling a medication organizer would be helpful until the patient is comfortable with completing this task. Discussion of anticipated side effects of the medications and how to manage them is necessary.

Nursing Process
Patient-Centered Collaborative Care

Antiretroviral Therapy

Assessment

- Obtain a patient history. Assess for signs and symptoms related to clinical progression of HIV disease. Assess physiologic and psychosocial needs; refer to medical care and psychological support as indicated.
- Perform medication reconciliation, including all prescription, over-the-counter (OTC), and herbal products. Assess for use of illegal drugs and other nonprescription drug use. Report potential drug-drug or drug-herbal interactions.
- Obtain a nutritional history to assess for nutritional deficits and for potential drug-food interactions. Assess for potential need for therapeutic lifestyle change if patient has or is at risk for developing a lipid disorder or diabetes.
- Assess readiness to learn and preferred method of instruction (written, verbal, pictorial).

Nursing Diagnoses

- Ineffective health self-maintenance related to knowledge deficit about HIV/AIDS
- Fear related to perceived stigma of HIV diagnosis
- Imbalanced nutrition related to loss of appetite and frequent stools
- Ineffective coping and/or compromised patient and significant other coping related to HIV diagnosis
- Risk for infection related to compromised immune system, especially if CD4 count is <200
- Ineffective health self-management related to complex medication management
- Knowledge deficit regarding drug interaction
- Readiness for enhanced health management related to expressed desire to improve knowledge about disease progression and outcomes of care
- Deficient knowledge related to medication management

Planning

- Patient's viral load will become and remain undetectable.
- Patient's CD4 count will become as high as possible.
- Patient will not experience secondary infections.
- Patient will participate in medical treatment and in spiritual and psychological support that best fits patient needs and belief system.
- Patient will promptly report new onset of symptoms and side effects.
- Patient will adhere to medication regimen and/or report difficulties related to adherence.

Nursing Interventions

- Educate patient about adherence to the therapeutic regimen by providing information on medications and timetable of dosing in the patient's preferred method of learning.
- Counsel patient about hand washing technique and methods to maintain health.
- Monitor laboratory reports for indications of decreasing CD4 counts and/or rising viral load; inform HIV health care provider.
- Refer patient for health care maintenance and appropriate health screening examinations, including PAP test, ophthalmology and dental examinations, and age- or risk-related colonoscopy.
- Refer patient for nutritional counseling as needed.
- Refer patient for spiritual support and/or for mental health or substance use counseling as needed.

Patient Teaching

General

- Explain how HIV may damage the immune system.
- Describe modes of transmission of HIV and ways to prevent transmission to others.
